Neurones express high levels of a structurally modified, activated form of pp60^{c-src}

Joan S. Brugge*, Patricia C. Cotton*, A. E. Queral*, John N. Barrett†, Doris Nonner† & Robert W. Kean†

† Department of Physiology and Biophysics, University of Miami, School of Medicine, Miami, Florida 33101, USA

Neural tissues contain high levels of the cellular homologue of the transforming protein of Rous sarcoma virus (RSV)¹⁻⁴, but neither the specific cell types expressing high levels of c-src, nor the function of the cellular src (c-src) protein has been determined. Using primary culture methods, we have found that pure neurones and astrocytes derived from the rat central nervous system (CNS) contain 15- to 20-times higher levels of the c-src protein than fibroblasts. However, the specific activity of the c-src protein from the neuronal cultures is 6- to 12-times higher than that from the astrocyte cultures. In addition, the c-src protein expressed in neuronal cultures contains a structural alteration within the aminoterminal region of the molecule that causes a shift in the mobility of the c-src protein on the SDS-polyacrylamide gels. These results indicate that a structurally distinct form of the cellular src protein that possesses an activated tyrosylkinase activity is expressed at very high levels in post-mitotic CNS neurones.

Figure 1 shows photomicrographs of the neuronal (A) and astrocytic (B) cultures used in this study. Neuronal cultures were obtained by dissociation of the metencephalon and lower telencephalon from 14-day rat embryos. The cells were cultured in a cerebrospinal fluid-like medium (N5) containing a neurotrophic fraction from horse serum⁵. This serum fraction promotes the maintenance of neurones in culture. The neuronal nature of the majority of cells (>98%) was confirmed by their ability to fire action potentials and bind tetanus toxin⁶ or anti-serum to neurofilaments⁷ (Fig. 1A). The few (<2%) non-neuronal cells were fibrous astrocytes that stained with antibodies to the glial fibrillary acidic protein (GFAP), a specific marker for astrocytes⁸.

Purified astrocytes were prepared from newborn rat cerebral cortices. Cultures were grown in N5 medium supplemented with 5% horse serum. Ninety-nine per cent of these cells displayed

flat-sheet like morphology and stained with antibody to GFAP (Fig. 1B). Other cells (1%) were neurones or fibrous astrocytes, as evidence by binding of tetanus toxin and monoclonal antibody to A2B5⁹.

Lysates from these cultured cells were assayed for pp60^{c-src} specific tyrosylkinase activity using a monoclonal antibody that recognizes the rat c-src protein¹⁰ (Fig. 2). ³²P-incorporation into pp60^{c-src} was used as a measure of the relative levels of pp60^{c-src} kinase activity. Neuronal lysates exhibited 8- to 10-times higher levels of ³²P incorporation into pp60^{c-src} than lysates from the cultured astrocytes, 4- to 6-times higher levels than lysates from embryonic brain tissue, and at least 20- to 30-times higher levels than lysates from embryonic limb tissue. Similar differences in the levels of kinase activity were detected when enolase was included in the assays to measure exogenous substrate phosphorylation¹¹. High levels of c-src protein kinase activity were maintained in the neuronal cultures that were carried in culture for as long as 4 months¹¹. These results indicate that the post-mitotic CNS neurones express and maintain high levels of the c-src protein kinase activity.

The higher levels of pp60^{c-src}-specific enolase phosphorylation detected in lysates from neurones compared with astrocytes could reflect differences in the steady-state levels of pp60^{c-src}, or differences in the specific activity of pp60^{c-src}. To examine these possibilities, we quantified levels of pp60^{c-src} protein and pp60^{c-src} kinase activity in neuronal and astrocyte cultures labelled with ³⁵S-methionine for 48 h (Fig. 3). Both the neuronal and astrocytic cultures contained 15- to 20-times higher levels of ³⁵S-methionine labelled pp60^{c-src} than rat fibroblast cultures, and contained levels comparable with those detected in RSV-transformed mouse cells (RSV-3T3 cells) (Fig. 3B). Since the ratio of trichloroacetic acid (TCA)-precipitable ³⁵S-c.p.m. per µg protein was similar for all of the cell lysates, the difference in the levels of ³⁵S-labelled pp60^{c-src} reflect the actual differences in the steady-state levels of pp60^{c-src}. Figure 3A shows that the pp60^{c-src}-specific phosphorylation of enolase was 6-times higher in lysates from neurones than in those from astrocytes. In replica experiments, lysates from neuronal cultures were found to possess 6- to 12-times higher levels of activity than lysates from astrocytes and 3-times lower than lysates from RSV-transformed cells. Since the levels of ³⁵S-methionine labelled pp60^{c-src} detected in neurones, astrocytes and RSV-transformed cells are similar, these results indicate that the specific activity of pp60^{c-src} from neurones is 6- to 12-times higher than that of astrocytes and 3-times lower than that of pp60^{v-src} in RSV-transformed mouse cells.

Lysates from neural retina and brain tissues contain a structurally distinct form of the cellular src protein that migrates as an electrophoretic variant of pp60^{c-src} on SDS-polyacrylamide gels¹². The alteration responsible for the shift in electrophoretic mobility maps within the aminoterminal region of pp60^{c-src}. To determine the cell-type producing this electrophoretic variant, the pp60^{c-src} protein was immunoprecipitated from lysates of ³²P-labelled neuronal, astrocytic or fibroblastic cultures (Fig. 4A). The proteins of molecular weight 60,000 were then subjected to partial proteolytic peptide mapping using *Staphylococcus* V8 protease (Fig. 4B). Figure 4C shows the pattern of cleavage of ³²P-labelled pp60^{c-src}. We have previously found that the V3 and V4 peptides derived from the pp60 protein from neural tissues migrate slightly more slowly than the analogous peptides of pp60 from CEFs or non-neural tissues, such as limb, liver, and heart¹². The V8 protease cleavage profile for the src protein immunoprecipitated from astrocytes is identical to that of pp60^{c-src} from fibroblasts. In contrast, the aminoterminal V3 and V4 peptides from the pp60^{c-src} protein expressed in neurons migrated more slowly than the V3 and V4 from the fibroblast and astrocyte pp60^{c-src} proteins. This electrophoretic variance was also observed in lysates from embryonic chicken neural tissues after 5 days' incubation and in embryonic rat neural tissues¹¹. A small amount of ³²P-incorporation was detected in V3 and V4 peptides that comigrated with the fibroblast-specific V3 and V4 peptides. It is not clear whether these peptides are

Fig. 1 Photomicrographs of cultures of neurones (A) and astrocytes (B) from embryonic and neonatal rat brain. A, For neurones, panels a-c show the phase contrast micrographs of the cells in d-f, which were stained with antibodies against neurofilament (NF)⁷ (d), tetanus toxin⁶ (e), or A2B5 antigen⁹ (f). For astrocytes (B) panel a shows the phase contrast micrograph of the cells in panel b stained with antibodies to glial fibrillary acidic protein (GFAP)⁸. Scale bar 20 μ m.

Methods. A, Neuronal cultures were obtained by dissociation of the metencephalon and lower telencephalon from 14-day Sprague-Dawley rat embryos. The tissue was disrupted into a cell suspension by gentle trituration and the cells were grown on collagen-polylysine coated 60-mm tissue culture dishes in N5 medium supplemented with 5% neurotropic fraction of horse serum as described⁵. For neurofilament staining (d), the cells were first fixed for 5 min in 10% buffered formalin and permeabilized with 95% ethanol. Cells were visualized using rabbit antiserum with 95% ethanol. Cells were visualized using rabbit antiserum to human NF protein, followed by fluorescein isothiocyanate (FITC)-conjugated goat anti-rabbit immunoglobulins (Ig). Tetanus toxin positive cells were visualized by incubation with tetanus toxin (2.5 μ g ml⁻¹) followed by horse anti-tetanus toxin and FITC-conjugated goat anti-horse whole serum. A2B5⁺ cells were visualized with monoclonal antibodies to A2B5 followed by tetramethyl-rhodamine isothiocyanate (TRITC) conjugated goat anti-mouse Ig. B, Astrocyte cultures were obtained by dissociation of the cerebral cortices from 1-day old Sprague-Dawley rats. The tissue was freed of meninges, and partially dissociated with pancreatin (1 mg ml⁻¹ in Ca²⁺/Mg²⁺-free Tyrodes) for 10 min. The cell suspension was centrifuged, and the pellet was dissociated by gentle repetitive pipetting and plated on collagen-polylysine coated 60-mm tissue culture dishes. Cultures were grown to confluency in N5 medium supplemented with 5% horse serum. Confluent cultures were treated with 10⁻⁵ M cytosine arabinose for 48 h to kill rapidly dividing cells. Cells were fixed and permeabilized as above and stained with rabbit antiserum against GFAP followed by FITC-conjugated goat anti-rabbit Ig. The percentage of cells binding antibodies was determined by counting approximately 1,000 cells per dish in four separate areas of the culture.

Fig. 2 Analysis of pp60^{c-src}-specific kinase activity of lysates of cultured neurones and astrocytes. Lane 1, astrocytes; 2, neurones; 3, adult mouse brain; 4, adult mouse limb. No 60K phosphoproteins were detectable in control immunoprecipitates obtained using anti-mouse Ig alone (see Fig. 3B, lanes 2, 4 and 7).

Methods. Cultures of neurones and of astrocytes were prepared as in Fig. 1 and lysed in 1 ml SLB detergent lysis buffer (1% sodium deoxycholate, 1% Nonidet, 0.075 mM NaCl, 5 mM EDTA, 10 mM Tris-HCl pH 7.0, 1 mM ethylene glycol-bis[β -aminoethyl ether]-N,N-tetraacetic acid) and clarified at 49,000g for 30 min. The protein concentration was then determined by the method of Lowry *et al.*³⁰ and samples were normalized for protein concentration (200 μ g) by the addition of SLB lysis buffer. pp60^{c-src} was then immunoprecipitated from the lysates and assayed for autophosphorylation according to Lipsich *et al.*¹⁰ using 1 μ l of a 1:100 dilution of ascites fluid from hybridoma 327 (MAb327) and 1 μ g of rabbit anti-mouse Ig. The kinase reaction was performed for 15 min at 22°C in kinase assay buffer (5 μ C [γ -³²P]ATP, 5 uM ATP, 10 mM Tris-HCl pH 7.4, and 5 mM MgCl₂). Samples were electrophoresed on a 7.5% Laemmli SDS-polyacrylamide gel³¹ and were autoradiographed with XAR (Kodak) film and a Lightning-Plus screen for 15 h.

derived from nonmodified *src* protein molecules present in the cultured neurones or from pp60 expressed in non-neuronal cells present in the neuronal cultures. This variant form of pp60^{c-src} was detected using three different antisera that recognize pp60^{c-src} (data not shown).

These results indicate that cultured neurones and astrocytes contain high levels of the pp60^{c-src} protein. However, the *c-src* protein expressed in neuronal cultures can be distinguished from the protein expressed in astrocytes in two ways: (1) the pp60^{c-src}

protein from neurones exhibits a 6- to 12-times higher specific activity of tyrosine phosphorylation than the protein from astrocytes, and (2) the pp60^{c-src} protein from neurones contains a structural alteration within the amino-terminal domain of the molecule. These results provide the first example of cell-type specific differences in the functional activity of a cellular proto-oncogene that involves structural modification of the protein rather than increased levels of the protein.

A correlation in activation of the *c-src* has also been observed

Fig. 3 Comparison of the specific activity of the cellular *src* protein in neurones and astrocytes. Electrophoresis sample buffer was added to half of the immunoprecipitate for analysis of the ^{35}S -methionine labelled $\text{pp60}^{\text{c-src}}$ (panel B), and the other half was assayed for enolase phosphorylation (panel A) by the addition of 2 μg of enolase and kinase reaction mix as described in Fig. 2. RSV-transformed mouse cells (lanes 1, 2); rat fibroblasts (F1-11 cells) (lanes 3, 4); rat astrocytes (lane 5); rat neurones (lanes 6, 7). **Methods.** Cultures of neurones and astrocytes were prepared as described in Fig. 1. These cells and rat F1-11 fibroblasts (from P. Jat, Massachusetts Institute of Technology) and RSV-transformed mouse 3T3 cells were labelled for 48 h with 100 μCi of ^{35}S -methionine in methionine-free medium supplemented with complete Dulbecco's minimum essential medium to 10% of the total volume. The medium was replenished after 24 h. The cells were lysed in SLB lysis buffer and the lysate clarified as described elsewhere³². The incorporation of ^{35}S -methionine into protein was assayed by TCA precipitation and the protein concentration was determined using the Lowry assay³⁰. The ratio of TCA-precipitable c.p.m. of ^{35}S -methionine to total protein was similar in all cell lysates. Sixty micrograms of each lysate was incubated with 1 μl MAb 327 and 1 μg of anti-mouse Ig (lanes 1, 3, 5, 6) or anti-mouse Ig alone as control (lanes 2, 4, 7). After washing, the immunoprecipitates were split. The levels of enolase phosphorylation were quantified by determining the c.p.m. of ^{32}P in excised gel pieces. (RSV-transformed cells, 7,270 c.p.m.; neurones, 2,480 c.p.m.; astrocytes, 402 c.p.m.; fibroblasts, 70 b.p.m.). The relative incorporation of ^{35}S -methionine into $\text{pp60}^{\text{c-src}}$ was determined by densitometric scanning of the 60K region of the autoradiogram using a Joyce-Loebbel Ephortec densitometer in the Rascor scan mode. In this experiment, the levels of incorporation of ^{35}S -methionine were equivalent for $\text{pp60}^{\text{c-src}}$ from the astrocyte and RSV-transformed cell cultures, 1.4-times higher in the neurone cultures, and 19-times lower in the fibroblast cultures.

between polyoma virus transformed cells and mouse 3T3 cells treated with platelet-derived-growth-factor (PDGF). The *c-src* protein associated with the middle T antigen of polyoma virus possesses 30- to 50-times higher levels of kinase activity and migrates with an electrophoretic mobility similar to that of $\text{pp60}^{\text{c-src}}$ from neurones^{13,14}. Ralston and Bishop have found that the *c-src* protein from mouse 3T3 cells treated with PDGF also contains an amino-terminal modification that alters both the electrophoretic mobility and the tyrosine kinase activity of $\text{pp60}^{\text{c-src}}$ (R. Ralston and J. M. Bishop, personal communication). In both of the latter systems, the modified aminoterminal fragment of $\text{pp60}^{\text{c-src}}$ was found to contain phosphotyrosine, which is not detectable in the unmodified form of the *c-src* protein. In contrast, we have not detected phosphotyrosine in the amino-terminal V8-protease fragments of $\text{pp60}^{\text{c-src}}$ expressed in neurones¹². It is possible that the activity of $\text{pp60}^{\text{c-src}}$ can be influenced by either tyrosine phosphorylation or other modifications within the amino-terminal domain of the molecule. Iba and Hanafusa have found that the *c-src* gene expressed by nontransforming retroviruses mutates at a high frequency¹⁵ to generate variants possessing elevated kinase activity¹⁶, which are capable of efficient transformation of fibroblasts¹⁵, suggest-

Fig. 4 Limited proteolysis of $\text{pp60}^{\text{c-src}}$ immunoprecipitated from lysates of cultured neurones and astrocytes. **A**, Cultures of neurones and astrocytes were prepared as described in Fig. 1. These cultures and Fisher rat 3T3 cells were labelled with ^{32}P (1 mCi ml^{-1}) for 4 h. Samples were lysed and $\text{pp60}^{\text{c-src}}$ was immunoprecipitated as described in Fig. 2 using 1 μl MAb 327 (1:100). The immunoprecipitates were electrophoresed on a 7.5% Laemmli SDS-polyacrylamide gel³¹. Lane 1, Fisher rat 3T3 cells; lanes 2 and 3, astrocytes; lanes 4 and 5, neurones. A doublet of $\text{pp60}^{\text{c-src}}$ is observed in lanes 4 and 5. **B**, Partial proteolysis of $\text{pp60}^{\text{c-src}}$. $\text{pp60}^{\text{c-src}}$ was excised and mapped by partial peptide proteolysis with 50 ng *Staphylococcus aureus* V-8 protease on a 12.5% SDS-polyacrylamide gel using the method of Cleveland³³. Following electrophoresis, samples were autoradiographed with XAR (Kodak) film and a Lightning-Plus screen. Lane 1, neurones; lane 2, astrocytes; lane 3, NIH Fisher rat 3T3 cells. The lines designate V-3' and V-4' peptides in lane 1. The dots indicate the V-3 and V-4 peptides in lanes 2 and 3. **C**, A map of $\text{pp60}^{\text{c-src}}$ showing the cleavage pattern observed following treatment with *Staphylococcus aureus* V-8 protease. Partial proteolytic digestion using low concentrations of V-8 protease cleaves the pp60 molecule into two fragments³⁴: (1) a peptide of M_r 34,000 (designated V1) which is phosphorylated on serine and contains the amino terminus of pp60 , and (2) a peptide of M_r 26,000 (designated V2) that is phosphorylated on tyrosine³⁵ and contains the carboxylterminus of $\text{pp60}^{\text{c-src}}$. Peptides of M_r 18,000 and 16,000 (designated V3 and V4) are generated by further cleavage of the V-1 peptide and both contain the aminoterminal of pp60 .

ing a large target region within $\text{pp60}^{\text{c-src}}$ in which mutations can activate the tyrosine kinase activity of $\text{pp60}^{\text{c-src}}$.

The expression of high levels of *c-src* kinase activity in post-mitotic neurones indicates that activation of *c-src* expression does not correlate with cell proliferation. This observation raises the question of whether either the *c-src* protein serves a specific function in neurones or the *c-src* protein is involved in the initiation or maintenance of neuronal differentiation. This result contrasts the functional activity of the viral *src* protein, which interferes with differentiation of neuroectoderm cells¹⁷, and other types of immature precursor cells¹⁸⁻²¹. The basis for this discrepancy is not known; however, recent evidence indicates that the viral *src* protein is functionally distinct from the cellular *src* protein. Although both proteins possess tyrosine specific kinase activity²²⁻²⁷, several laboratories have found that overexpression of the *c-src* protein does not mimic the transforming effects of the viral *src* protein^{15,28,29} and the phosphotransferase activity of the *c-src* protein is qualitatively and quantitatively different from that of the viral *src* protein (ref. 16; P. M. Coussens and D. Shalloway, personal communication). These differences in kinase activity could lead to changes in the substrate specificity of the *v-src* protein compared with the cellular

src protein *in vivo*, thus eliciting cellular responses not brought about by *c-src*-mediated tyrosine phosphorylation of cellular proteins.

Identification of neurones as the type of cell that specifically expresses high levels of the *c-src* protein kinase activity provides a focus for future investigation of the function of the cellular *src* protein. Neurones could provide an ideal system to probe the function of *c-src* since the physiology of these cells is so well characterized. In addition, the availability of cell cultures of neurones containing minimal contamination from other neural or stromal cell types offers many advantages over the use of whole tissues.

We thank Maureen Jarvis Maurer for helping with some of the experiments and Kathleen Donnelly for secretarial assistance. This work was supported by PHS grant CA28146 from the NCI (J.C.S.) and NS12207 from NINCDS (J.N.B.) and National Parkinson Foundation (R.W.K.). We thank S. H. Yen, L. Eng and M. Nirenberg for antiserum and R. O. Thompson for tetanus toxin.

Differentiation of PC12 phaeochromocytoma cells induced by *v-src* oncogene

Stefano Alemà, Patrizia Casalbore, Elisabetta Agostini & Franco Tatò*

Istituto di Biologia Cellulare, CNR, Rome, Italy and *Dipartimento di Biologia Cellulare e dello Sviluppo, Sezione Scienze Microbiologiche, Università La Sapienza, Rome, Italy

PC12 rat phaeochromocytoma cells^{1,2} are a model system that can be used to study both neuronal differentiation and the mechanism of action of nerve growth factor (NGF)³. PC12 cells respond to NGF protein by shifting from a chromaffin-cell-like phenotype to a neurite-bearing sympathetic neurone-like phenotype^{2,4,5}. Here we present data on the effect of infection of PC12 cells with retroviruses carrying the *src* oncogene of Rous sarcoma virus⁶. Previous studies have demonstrated that the expression of *src* severely affects the synthesis and accumulation of differentiated cell products in a variety of cell types⁷⁻⁹. We show that in the PC12 cell system, expression of *v-src* appears to have an inductive effect on differentiation that resembles the action of a 'physiological' growth factor.

PC12 cells grown without exogenously supplied NGF do not possess neurites. When NGF is added to cultures, there is a lag of about 24 h before neurites are first detectable, after which they appear over several days; by this time >95% of cells possess neurites¹. PC12 cells, cultured on collagen-coated dishes as described previously¹, were infected with the mammaltropic strain Schmidt-Ruppin D (SR-D) of Rous sarcoma virus (RSV) (multiplicity of infection (MOI) between 1 and 10 as assayed on susceptible chicken embryo fibroblasts). After a lag of about 48-72 h after infection, a fraction of the cells started to undergo a marked phenotypic conversion, shown by the emission of short and long neurites, as in NGF-treated cells (Fig. 1). Eventually, after 7-10 days, a variable proportion of infected cells (up to 30%, depending on MOI and experiment) exhibited long neurites. Differentiated cells conserved their phenotype in culture for several days, and could be replated after trypsinization. Severed neurites re-grew within 24-48 h. Parallel experiments were performed using PC12 cells that had been pretreated with

mitomycin C (1 µg ml⁻¹ for 18 h), thus eliminating further cell proliferation. In mitomycin C-treated cells, only neurite extension promoted by NGF took place, but its time course was considerably shortened, thus reinforcing the notion that division is not required for differentiation in this system⁴. On the contrary, infection with SR-D failed to elicit a differentiated phenotype in mitomycin C-treated PC12 cells, suggesting that establishment of infection¹⁰ is a necessary event (data not shown). Antibodies directed against NGF, although capable of fully inhibiting NGF-induced neurite extension, did not inhibit the outgrowth elicited by RSV infection. Conversely, putatively infected cells that did not emit short or long neurites continued to divide actively and were competent to extend fibres after cultivation in the presence of NGF. When tissue culture fluids from SR-D-infected PC12 cultures were tested for induction of morphological differentiation in uninfected cells, no neurite extension was detected in such cultures, making it unlikely that the observed phenomenon was a result of the release of long-range acting substances endowed with NGF-like properties.

Further evidence that differentiation of RSV-infected cells is under the continuous control of the *src* gene was provided by a genetic analysis using a variety of mammaltropic viral strains and their conditional mutants⁶. Thus, both the B77 strain of RSV and a murine recombinant retrovirus containing the *src* gene (MRSV)¹¹ were capable of inducing morphological differentiation of PC12 cells with similar kinetics to those exhibited by SR-D, albeit with a lower efficiency (Fig. 1d). PC12 cells, infected with the temperature-sensitive (*ts*) mutant LA339-B77 (ref. 12) and passaged at 39.5 °C, were indistinguishable from uninfected controls. Following a shift to 35 °C, however, the *ts*-LA339-infected cells within 2-3 days underwent a morphological transition to neurone-like cells with long processes (not shown). Infection with transformation-defective (*td*) B77 alone as well as with the non-mammaltropic strains SR-A and *ts*-LA24 did not produce any alteration in the morphology or growth behaviour of the cells. To substantiate that the emission of neurites was under the control of the *src* gene, we used the immune complex kinase assay¹³ to test for the presence of the *src* primary product, pp60^{v-src} (ref. 14), in RSV-infected cultures (Fig. 2). SR-D-infected PC12 cells at 5 days post-infection contained elevated levels of pp60^{v-src} (Fig. 2a), comparable with those of a SR-D-transformed clone of the rat myogenic cell line

Fig. 1 Phase-contrast and catecholamine fluorescence (insets) micrographs of fixed PC12 cells undergoing differentiation. *a*, Control, uninfected PC12 cells; *b*, NGF-treated cells; *c*, SR-D-infected cells; *d*, MRSV-infected cells, enriched through serum deprivation. The percentage of differentiated cells with long (beyond two cell body diameters) neurites was difficult to assess because PC12 cells have a strong tendency to aggregate. It was often possible to see many neurites emerging from cellular aggregates composed of tens of cells. Neurites in RSV-infected cultures possessed flattened growth cone-like structures and often had varicosities, which are a specific attribute of sympathetic-like cells, thus distinguishing RSV-induced processes from the short ephemeral extensions produced following certain treatments³¹.

Methods. PC12 cells were infected with RSV at a MOI of 1–10 in the presence of 2 μ g polybrene per ml and thereafter grown in standard culture conditions or in the absence of serum. After attaining confluence, cultures were trypsinized and seeded in triplicate at 2×10^5 cells per 35-mm collagen-coated dishes and further incubated at the appropriate temperature for 5 days. NGF-treated cells were cultured in medium supplemented with 100 ng per ml of 2.5S NGF³² (a kind gift of D. Mercanti); the medium was changed every third day. Photographs were taken after fixation with 3% paraformaldehyde. Catecholamines were visualized by the glyoxylic acid method³³.

L8 (ref. 15). In contrast, pp60^{v-src} was expressed at significantly lower levels in cultures of Rat-1 cells freshly (5 days) infected with SR-D at the same MOI (Fig. 2*a*). Levels of pp60^{c-src}, the cellular *src* kinase activity¹⁶, remained constant when assayed 10 days after addition of NGF or infection by RSV (Fig. 2*b*).

SR-D-infected and differentiated cells remain viable when cultivated in serum-free conditions, whereas undifferentiated ones die within a few days. This property, also shared by NGF-treated PC12 cells¹⁷, has been exploited as a simple means to obtain cultures highly enriched in differentiated cells, and suitable for assaying the expression of two constitutive markers of the PC12 cell line: storage of catecholamines and α -bungarotoxin binding sites^{2,18}. Neither marker was significantly altered (Fig. 1, insets and data not shown), suggesting that in these cells expression of high levels of pp60^{v-src} does not interfere with the differentiative programme.

We next investigated whether morphologically differentiated cells can synthesize DNA or whether differentiation is accompanied by a progressive withdrawal from the cell cycle, as shown previously for NGF-treated PC12 cells². This was monitored by pulsing the cells with ³H-thymidine in high serum for 48 h and locating labelled cells by autoradiography. The autoradiographic studies showed that while most control PC12 cells, grown in serum, were labelled, a considerable proportion of serum-free enriched, differentiated cells, bearing neurites many cell body diameters in length, had ceased to incorporate ³H-thymidine (Fig. 3). Differentiated PC12 cells, selected through serum deprivation, showed a further three-fold increase in pp60^{v-src} specific activity, a finding which indicates strongly that differentiated cells do express levels of kinase usually associated with transformation in other rat cell types (see SR-D-L8 in Fig. 2).

Our results show that while expression of v-*src* in the PC12 cells system can efficiently induce these cells to progress further along their differentiative pathway, it does not seem to suppress two specific differentiation markers constitutively expressed in the cell line. This may seem surprising in view of the well-known effects of *src* in a wide range of RSV-transformed avian cell types in culture. In all systems in which *src* has a demonstrated

Fig. 2 Expression of pp60^{src} in uninfected and RSV-infected PC12, Rat-1 and L8 cells. *a*, pp60^{v-src} kinase activity in cell extracts of SR-D-infected Rat-1 (lanes 1, 2) and PC12 cells (lanes 3, 4) 5 days post-infection; SR-D-transformed L8, clone F (lanes 5, 6). Lanes 2, 4 and 6 are assays carried out on extracts diluted 1 to 5 in order to check linearity of assay. *b*, pp60^{c-src} activity in extracts of control uninfected (lane 1), NGF-treated (lane 2) and SR-D-infected (lane 3) PC12 cells. hc, IgG heavy chain.

Methods. PC12 and Rat-1 cells were cultured and infected as described in Fig. 1 legend. L8 cells, a rat myogenic cell line, were infected by SR-D and transformed cells were isolated and cloned as described in ref. 15. The *src*-encoded transforming protein has been demonstrated to possess kinase activity capable of phosphorylating the heavy chain of IgG. The *src* kinase activity was measured in cultures washed with phosphate-buffered saline and frozen *in situ* at -80°C . Briefly, cells were lysed in 1% NP40-containing buffer, also containing 0.2 mM phenylmethylsulphonyl fluoride. After clarification at 80,000g for 30 min, aliquots of extracts, normalized for total protein content (200–500 $\mu\text{g ml}^{-1}$), were challenged with 5 $\mu\text{l ml}^{-1}$ of two different tumour-bearing rabbit sera. The first antiserum (obtained from P. Enrietto) recognizes pp60^{src} of Prague-A strains of RSV and cellular *src* but does not cross-react significantly with pp60^{src} from the SR-D strain. The second antiserum (obtained from B. Friis) reacts poorly with pp60^{v-src} but precipitates pp60^{v-src} from both SR-D and Prague-A strains. The combined use of the two antisera allows the detection of relative variations in the kinase activity of the viral (*a*) and cellular (*b*) kinases without mutual interference. Immune complexes were reacted at 20°C for 10 min in 50 mM HEPES buffer, pH 7.5, 5 mM MgCl₂, 5 mM MnCl₂, 4 μCi of [γ -³²P]ATP and then analysed on 10% SDS-polyacrylamide gels.

Fig. 3 Micrographs of representative fields of autoradiographs from cultures of control (a, b) or SR-D-infected (c, d) PC12 cells. PC12 cells that had been cultured for 48 h either in serum-free medium (SR-D-infected) or in 10% fetal calf serum (control cultures) were transferred to high serum and incubated for 48 h with ^3H -thymidine ($2\ \mu\text{Ci ml}^{-1}$, $40\ \text{Ci mmol}^{-1}$, NEN). The cells were then fixed and processed for autoradiography as described elsewhere⁹. Phase-contrast (a, c) and bright-field (b, d) pictures of the same field are shown to better contrast ^3H -thymidine incorporation in nuclei and morphology of differentiated cells.

effect on differentiation, the effect seems to involve a direct and specific suppression of a given differentiation programme^{7-9,19,20}. It was recently shown, however, that macrophages could be infected by RSV, without discernible alterations in proliferative or differentiative parameters²¹. Neither the failure of macrophages to transform nor the ability of PC12 cells to differentiate can be explained by reduced levels of pp60^{v-src} (ref. 22 and Fig. 2). These cells may, however, lack a developmentally regulated (lineage-specific) function, which is essential in the pathway leading other cell types to transformation²².

The vertebrate *c-src* gene is expressed at high levels and in a stage- and cell-type-specific fashion in the nervous system^{23,24}, a finding that has led to the hypothesis that pp60^{c-src} may be involved in the control of the differentiative processes of neural crest-derived cells²⁴. Whether this speculative argument is compatible with the available evidence remains to be assessed. For the moment, the present results provide some qualitative supporting evidence, notwithstanding the known structural and functional differences between *c-* and *v-src* gene products²⁵. In this context, it is noteworthy that expression of the *c-fos* proto-oncogene, while causing transformation in mammalian fibroblasts²⁶, promotes differentiation of teratocarcinoma stem cells²⁷.

A final intriguing question concerns the possible relationship between the mechanism of action of NGF and the biochemical events that accompany the activity of pp60^{v-src}, such as tyrosine phosphorylation of proteins or increased turnover of the phosphoinositides²⁹. Experiments are in progress to test this hypothesis and whether *v-src* triggers an aberrant type of differentiation in PC12 cells or shares a common pathway with NGF. However, receptor-bound growth factors such as epidermal growth factor share similar transduction events with *v-onc*-encoded transforming proteins²⁹, yet do not induce differentiation of PC12 cells³⁰. Therefore, there seems to be a high degree of molecular specificity in the multiple responses triggered by NGF and *v-src*.

We thank B. Friis and P. Enrietto for gifts of specific antibodies, A. Cattaneo and G. Falcone for valuable suggestions, A. Calconi and A. M. Salvia for technical assistance, and A. Sebastiano for help in preparation of the manuscript. This investigation was supported by Consiglio Nazionale delle Ricerche under P. F. Oncologia (84.00822.44) and Medicina Preventiva.

The genome of the avian retrovirus MH2 contains, in addition to the *v-myc* oncogene shared with three other avian retroviruses (MC29, CMII and OK-10), a second cell-derived oncogene, *v-mil* (refs 1-3). Like the three other viruses, which contain only *v-myc*, MH2 induces mainly liver and kidney carcinomas in fowl and

Fig. 1 Growth kinetics of virus-infected chicken neuroretina cells. NR cells were infected with MH2 (wild-type), MC29, CMII, OK-10 and RAV-1 (a) and MH2, MH2-PA200, MH2-cl.16, MH2-cl.25, MH2-OB and RAV-1 (b), then seeded at low density ($\sim 2 \times 10^5$ cells per 5-cm dish). Medium was renewed daily and cells from two aliquot dishes were counted as indicated. Viruses were obtained by RAV-1 superinfection of non-producer clones. (c) Constructed mutants. B, *Bam*HI; E, *Eco*RI; H, *Hind*III; Hp, *Hpa*I; K, *Kpn*I; P, *Pst*I; Pv, *Pvu*I; X, *Xho*I; L, long terminal repeat. Open boxes represent proviral sequences and closed boxes flanking cellular sequences.

Methods. Preparation of NR cell cultures and growth assay: Neuroretinas were dissected from 7-day-old chick embryos. Cells were dissociated and resuspended in Eagle's basal medium (BME) supplemented with 5% fetal calf serum. Dishes (35 mm) containing $\sim 2 \times 10^6$ cells were infected with the various viruses. When proliferation became evident in wild-type MH2-infected cells (7–10 days post-infection), cultures were passaged once in 5-cm dishes until MH2-infected cells reached confluency, and then seeded at low density for growth assay. Isolation of class I mutants MH2-cl.16, MH2-cl.25: Two viral stocks were used. MH2 (RAV-1) was obtained by superinfecting a non-producer quail embryo fibroblast (QEF cells) clone, MH2-QB2 (ref. 11), with RAV-1. MH2 (RAV-3) was kindly provided by Dr C. Moscovici. Both viruses exhibited comparable mitogenic and transforming properties in NR cells and directed the synthesis of P100^{gag-mil} in transformed cells. QEF cells were infected at low multiplicity with MH2 (RAV-1) or MH2 (RAV-3) and seeded 6 h later at low density in soft agar-containing medium. Colonies of transformed cells developed within 2 weeks and were individually transferred to 35-mm dishes. At confluency, RAV-1 was added to rescue virus from occasional non-producer clones. Supernatants were used to infect NR cells. Media from two such clones, 16 and 25, contained virus which failed to induce NR cell growth. MH2-cl.16 originated from MH2 (RAV-1) and MH2-cl.25 from MH2 (RAV-3). The two mutant viruses were subcloned on QEF cells in soft agar, and virus stocks rescued from non-producer colonies by RAV-1 superinfection were unable to induce NR cell multiplication, but transformed chicken fibroblasts and macrophages. Isolation of class II mutant MH2-PA200: MH2-PA200 was isolated by end-point dilution of MH2 on NR cells. NR cells were infected with serial twofold dilutions of MH2 (RAV-1), to determine the highest dilution of the virus inducing cell proliferation. The reciprocal of this dilution defined the mitogenic titre of the virus in mitogenic units (MU) per ml. Several NR cultures were then infected with 0.3–0.5 MU per plate and superinfected 1 week later with RAV-1 to rescue virus from occasional non-producer cells. Virus produced by one such culture was selected for this study because it induced NR cell multiplication in the absence of morphological transformation. This variant was designated MH2-PA200 (RAV-1). Strategy used for constructed mutants (c): DNA of pMH2-Hd plasmid¹ was digested with *Bam*HI, ligated and transfected in *Escherichia coli* HB101 cells. A clone was selected, pMH2-OB, which lacked the 1.3-kb *Bam*HI restriction fragment derived from the *gag* gene. Sequence analysis around the recombination site indicated that translation of the pMH2-OB RNA should result in the synthesis of a product containing the amino-terminal 52 amino acids of p19^{gag} linked to 5 amino acids derived from the *v-mil* sequence in a +1 frameshift (C. Henry and B. Debuire, unpublished data). To construct the MH2-LI200 mutant, DNA of pMH2-Hd plasmid was partially cleaved by *Sal*I endonuclease and cohesive termini were filled in by treatment with the Klenow fragment of DNA polymerase I. This generated a new *Pvu*I site as expected, and should result in a +1 frameshift in the translation of the *v-myc* sequence. Infectious virus (MH2-OB) was rescued from pMH2-OB DNA transfected cells using RAV-1 as helper virus.

transforms fibroblasts and macrophages *in vitro*⁴. However, MH2 and MC29 differ in their biological properties when assayed on cultures of chicken embryo neuroretina (NR) cells. Indeed, NR cells, which normally do not multiply *in vitro*, are induced to proliferate and become transformed upon infection with MH2, whereas infection with MC29 has no apparent effect on these cells^{5,6}. To analyse the functions of the two oncogenes of MH2, we isolated spontaneous and *in vitro*-constructed mutants of this virus and investigated their effects on NR cell multiplication and transformation. We report here that expression of *v-mil* is sufficient to induce NR cell proliferation, although it does not result in cell transformation. In addition, viruses expressing only the *v-myc* oncogene fail to induce any detectable change in NR cells. However, cooperation of the two oncogenes is required to achieve transformation of NR cells by MH2.

Neuroretinas, dissected from 7-day-old chicken embryos, were dissociated into essentially single-cell suspensions and plated in Eagle's basal medium containing 5% fetal bovine serum. These cultures contain only neurones and glial cells^{7,8}. Infection of NR cells with MH2 resulted within 7–10 days in the appearance of actively proliferating cells which could be readily subcultured for several generations (Fig. 1a). These cells were morphologically transformed and displayed anchorage-independent growth capacity (results not shown). In contrast, NR cells infected with MC29, CMII or OK-10, or with the helper virus RAV-1 used as a control, retained the morphology and limited growth capacity of normal cells (Fig. 1a). This lack

of phenotypic response was not due to a block in virus replication, because the *v-myc* products were synthesized in infected cells and supernatants of infected NR cultures contained virus that efficiently transformed chicken embryo fibroblasts (results not shown).

To analyse the biological properties of the two oncogenes of MH2 further, we isolated two classes of virus mutants by their capacity to alter the phenotype of NR cells. Class I mutants were selected because they were unable to induce NR cell proliferation (see Fig. 1 legend). Two such mutants, MH2-cl.16 and MH2-cl.25, were isolated from two distinct viral stocks. MH2-cl.16 and MH2-cl.25, like wild-type MH2, transformed chicken embryo fibroblasts and macrophages (T. Graf, personal communication). In contrast to wild-type virus-infected cultures, NR cells infected with either mutant were not transformed, nor were they stimulated to grow (Fig. 1b). An additional mutant virus, MH2-OB, possessing similar biological properties (Fig. 1b), was obtained by deleting most of the *gag* sequence in plasmid pMH2-Hd (ref. 1) which contains a biologically active provirus (this yields a premature termination of the *gag-mil* protein, see Fig. 1c).

Two class II mutants were isolated as follows. Mutant virus MH2-PA200 was selected because it induced proliferation of NR cells, without morphological transformation (Fig. 1 legend). Such cells could be subcultured for many generations but ultimately did senesce (after ca. two months). The second mutant, MH2-LI200, with similar biological properties, was derived from

Fig. 2 Characterization of *gag* and *mil* related proteins synthesized in avian cells infected by wild-type and mutant MH2 viruses. Chicken NR cells transformed by wild-type MH2 (a), or infected by MH2-PA200 (b) and fibroblasts transformed by MH2-cl.25 (c), MH2-cl.16 (d) and MH2-OB (e) were incubated for 3 h in the presence of 30 $\mu\text{Ci ml}^{-1}$ of L-35S-methionine (specific activity 1,000 Ci mmol $^{-1}$), lysed and immunoprecipitates prepared as described previously²². Sera used were as follows: lanes 1, pre-immune rabbit serum; lanes 2, rabbit anti *gag* serum; lanes 3, rabbit antiserum prepared to a bacterially expressed protein corresponding to the carboxy terminus of P100^{gag-mil} (F.D. and J.G., in preparation). Immunoprecipitated proteins were analysed by SDS-polyacrylamide gel electrophoresis as described by Laemmli²³ followed by fluorography on the dried gel.

plasmid pMH2-Hd (ref. 1) by generating a frameshift mutation in *v-myc*, resulting in the premature termination of its translation product (Fig. 1c legend).

The P100^{gag-mil} translation product of *v-mil*^{9,10} was readily detected by immunoprecipitation of lysates of ³⁵S-methionine-labelled cells infected with either wild-type MH2 or class II mutants (that is, MH2-PA200, Fig. 2b) using antiserum specific for *gag* proteins (lanes 2) or for a bacterially expressed *v-mil* protein (lanes 3). In contrast, no *v-mil* specific protein was detected in fibroblasts transformed by class I mutants (Fig. 2c-e, respectively).

We next performed blot analyses of RNA isolated from cells infected with either wild-type or mutant viruses. As expected from previous studies^{1,11}, cells infected with wild-type MH2 synthesized a 5.7-kilobase (kb) genomic RNA detectable with either a *v-mil* or a *v-myc* probe (Fig. 3c, lanes 1 and 2, respectively) and a 2.8-kb subgenomic RNA detected with a *v-myc* probe only (Fig. 3c, lane 2). The 5.7-kb genomic RNA and the 2.8-kb subgenomic RNA species are known to encode respectively the P100^{gag-mil} and p60/61^{myc} proteins^{12,13}. The 2.8-kb *myc*-specific RNA was detected in fibroblasts transformed by MH2-cl.16, MH2-cl.25 and MH2-OB at levels similar to those observed in cells transformed by wild-type MH2 (Fig. 3a, b, d, lanes 2). No virus-specific RNA hybridizing to the *v-mil* probe was detected in cells infected with mutant virus MH2-cl.16 and MH2-cl.25, indicating that these mutants had lost most or all of the *v-mil* sequences. In addition to the 2.8-kb RNA, cells infected with MH2-OB synthesized a 4.4-kb RNA that hybridized to both *v-mil* and *v-myc* probes (Fig. 3d). This, together with the size of the fragment deleted to generate pMH2-OB (1.3-kb, see Fig. 1c), led us to conclude that the 4.4-kb RNA was the genomic RNA of MH2-OB. The 4.0-kb species detected by the *v-mil* probe corresponds to the previously described *c-mil* endogenous transcript in fibroblasts¹ and appears on long exposures (Fig. 3a, b, lanes 1).

In contrast, no RNA hybridizing to a *v-myc* probe was detected in NR cells infected with MH2-PA200 (Fig. 3e, lane 2). The only virus-specific RNA synthesized in these cells was a 5.7-kb RNA hybridizing to a *v-mil* probe (Fig. 3e, lane 1). This RNA also hybridized to an *env* probe (not shown). The MH2-PA200 provirus has been molecularly cloned and the restriction map of this provirus suggests that it has been generated by recombina-

Fig. 3 Size of viral RNA in MH2 wild-type or mutant infected chicken fibroblasts and NR cells. Northern blots of polyadenylated RNA were probed in lanes 1 with a 1.1-kb *Bam*H1-*Hpa*I *v-mil*-specific fragment (see Fig. 1c) and in lanes 2 with a 0.6-kb *Aha*I/*Hae*III-*Eco*RI fragment derived from the last exon of the chicken *c-myc* locus²⁴. The probes were labelled with ³²P by nick translation and used as described previously¹¹. Viruses used are listed across the top of the figure. Lanes a-d, transformed fibroblasts; lane e, MH2-PA200-infected NR cells. Transformed fibroblasts in lane c were obtained after transfection with a molecularly cloned MH2 provirus (pMH2-Hd)¹ together with a plasmid containing a biologically active RAV-1 provirus (a generous gift from Dr J. M. Bishop).

tion between wild-type MH2 and its helper virus, resulting in the probable substitution of $\Delta\text{gag-pol-}\Delta\text{env}$ sequences of the helper by $\Delta\text{gag-mil-}\Delta\text{myc}$ sequences from wild-type MH2 (to be published elsewhere).

MH2-PA200 and MH2-LI200 were as efficient as wild-type virus in inducing proliferation of NR cells (Fig. 1b). However, in contrast to wild-type virus-infected cells, NR cells infected with either mutant were not morphologically transformed nor were they able to form colonies in soft agar-containing medium. Both virus mutants also failed to transform macrophages (T. Graf, personal communication) and chicken embryo fibroblasts (not shown). The latter is surprising since the mouse virus MSV3611¹⁹ that contains *v-raf*, the mouse-derived counterpart of *v-mil*, readily transforms mouse fibroblasts. This may indicate a structural difference in the two transduced genes or a different response of the target cells in the chicken and mouse species. Finally, reconstitution experiments showed that proliferating NR cells infected with MH2-PA200 became rapidly transformed on superinfection with MC29 (not shown).

The results presented here show that the ability to induce proliferation and transformation of NR cells from 7-day-old chicken embryos is a characteristic property which distinguishes MH2 from the other *v-myc*-containing viruses. Characterization of mutants MH2-PA200 and MH2-LI200 demonstrates that expression of *v-mil* is both necessary and sufficient to account for the mitogenic property of MH2 in NR cells. However, infection of NR cells and fibroblasts with mutant viruses expressing only *v-mil* does not result in cell transformation. That the mutant MH2-LI200 exhibits similar biological properties indicates that the *v-mil* sequence of MH2-PA200 is similar to that of wild-type virus. The *v-mil* gene shares significant sequence homology with other oncogenes of the *src* gene family¹⁴ which induce both proliferation and transformation of NR cells^{5,15}. Interestingly, mutants in the *src* gene that, like *v-mil*, induce NR cell multiplication without transformation, have been described⁶. Several oncogenes of the *src* gene family encode plasma membrane-associated protein kinases specific for tyrosine residues, a property also shared by several growth factor receptors^{16,17}. In contrast, P100^{gag-mil} appears localized in the cytoplasm of transformed fibroblasts and is associated *in vitro* with a serine/threonine-specific protein kinase activity^{18,19}. Such differences in intracellular localization and/or kinase specificity

may explain the lack of transforming capacity of the *v-mil* product. Whether the mitogenic signals induced by the expression of *v-mil* and *v-src* in NR cells share common primary targets remains to be determined.

Mutants of MH2 expressing only the *v-myc* oncogene fail to induce transformation and proliferation of NR cells in the conditions used, although they still transform fibroblasts and macrophages. Therefore, the *v-myc* genes of MH2 and MC29 seem to be functionally indistinguishable, despite their structural differences^{20,21}. However, transformation of NR cells by the *v-myc* gene can be established in cells already infected with mutants expressing only the *v-mil* gene. These results indicate that transformation of chicken NR cells by MH2 requires cooperation of the two oncogenes.

Telomeric reciprocal recombination as a possible mechanism for antigenic variation in trypanosomes

E. Pays, M. Guyaux, D. Aerts*, N. Van Meirvenne* & M. Steinert

Department of Molecular Biology, University of Brussels, 67, rue des Chevaux, B1640 Rhode Saint Genèse, Belgium

* Tropical Medicine Institute, Antwerp, Belgium

In African trypanosomes, antigenic variation is achieved through differential gene activation, with one antigen gene being expressed at a time among a large collection of antigen-specific sequences. Transcription of the antigen gene always takes place in a telomere, but different telomeres can alternatively act as the expression site¹⁻⁴. Telomeric antigen genes can be expressed without apparent DNA rearrangement⁵⁻⁸, but they can also, like non-telomeric genes, have access to the telomeric expression site through a duplicative transposition mechanism resembling gene conversion⁷⁻¹⁰. We report here that, as previously suggested^{3,6}, telomeric genes may use another route to be activated. This mechanism of gene activation is by reciprocal crossing-over upstream from the gene, in the so-called 'barren' region. This allows the antigen gene to be placed in the previously activated telomere, while inactivating the formerly expressed gene by recombination into a silent environment. At least for the telomeric antigen gene described here, three possible activation mechanisms coexist.

In *Trypanosoma brucei*, antigen gene activation frequently involves DNA rearrangements, although occasionally telomeric antigen genes seem to be expressed without^{6,8,11} or with only minor^{3,7} concomitant changes. To explain this mode of gene activation, we suggested that telomeric genes could be placed in the expression site following reciprocal exchange with the previously expressed gene^{3,6}. However, in the clone derivation AnTat 1.1B→1.6C→1.1G, we observed that the antigen genes involved were expressed without apparent rearrangement, even at the chromosome level: the gene *1.1B*, carried by a 225-kilobase (kb) minichromosome, remains in the same location whether expressed (in clones AnTat 1.1B and 1.1G) or not (in clone AnTat 1.6C), while the *1.6* gene is always found in a large chromosome irrespective of whether it is active or inactive (M.G. and E.P., unpublished results). Similar observations have been made in other cases of gene activation without DNA duplication^{2,12} and suggest that at least some telomeric antigen genes can be activated *in situ*, although the nature of the activation mechanism remains unknown.

At the other extreme, telomeric antigen gene activation may involve important DNA rearrangements. This is true for the AnTat 1.1C→1.3B switch, where a telomere, carrying a 1.3-specific sequence, has converted another telomere over more than 40 kb³. Gene conversions of this size are unusual and are thought to result from a lack of homology between the interacting telomeres, so that the conversion can only be triggered far upstream from the gene. Therefore, we considered another switch involving the same two telomeres, but in reverse order, to check if it would again lead to a large conversion. This was achieved through cloning AnTat 1.10D from AnTat 1.3A (see Fig. 1 legend for details). Indeed, the two telomeres expected to be involved in this antigenic switch are the same as those involved in the AnTat 1.1C→1.3B clone derivation. These telomeres carry the *1.3* and *1.10* genes, respectively; the latter is a member of the *1.1* gene family, which was partially converted in the AnTat 1.1C clone^{3,10}. Surprisingly, we found that in the AnTat 1.10D clone, the *1.10* gene was activated without duplication, although its environment was completely altered. Restriction mapping and determination of the chromosomal location of the two telomeres concerned unambiguously revealed that the switch from AnTat 1.3A to 1.10D was associated with a reciprocal event in which the *1.10* gene recombined into the active *1.3A* telomere. In turn, the previously expressed gene (*1.3*) was found to have recombined into the old *1.10* gene environment, where it became inactivated.

In the AnTat 1.3A clone, the actively transcribed *1.3* gene is a copy (an 'expression-linked copy' or ELC) of the single *1.3*-specific sequence, the 'basic copy' (BC)⁹. Figure 1 shows the restriction map of the telomere harbouring the *1.3A* ELC and a map of the telomere carrying the silent *1.10* gene in the same clone, while Fig. 2 shows the chromosomal location of these two sequences in the AnTat 1.3A clone. As noted previously¹², the *1.10* gene is located on a large chromosome, like all the *1.1* gene family members; the *1.3A* ELC is transcribed from a small 225-kb chromosome, while the *1.3* BC is on a 1,000-kb chromosome (ref. 12 and Fig. 2).

In the AnTat 1.10D clone, the restriction maps of the 5' environment of these two sequences have become exchanged, the crossover point lying in a 4-10-kb region devoid of most restriction sites ('barren' region), usually found upstream from the trypanosome antigen genes¹³ (Fig. 1). Accordingly, on a chromosome-sized AnTat 1.10D DNA blot (Fig. 2), it is the *1.3A* ex-ELC which is present on a large chromosome, instead of the 225-kb one, while the *1.10* gene is now found on the 225-kb chromosome.

Figure 3 shows that the *1.10* gene is really the sequence transcribed in the AnTat 1.10D clone. The 2-kb *EcoRI* fragment characteristic of the *1.10* gene and 5' neighbourhood^{3,10} is hypersensitive to DNase I in isolated AnTat 1.10D nuclei (Fig. 3a, arrowhead), as are transcriptionally active genes in other trypanosome clones¹⁴ or other eukaryotes¹⁵.

This sequence was not duplicated in the AnTat 1.10D clone,

Fig. 1 Restriction maps of the telomeres carrying the *1.3* and *1.10* antigen genes, in clones AnTat 1.3A and 1.10D. ~, Antigenic variation; ~, cloning. In the restriction maps, the open and solid boxes represent the known extent of the *1.3* and *1.10* antigen genes, respectively, as deduced from complementary DNA analysis^{3,9,10}; the extent of the cDNA probes used to construct the maps by hybridization with Southern genomic blots²⁷ is delimited by arrows under the active genes. For each variant, the transcribed telomere is marked by a star. The bracketed sites are the targets for a telomeric DNA modification system, as discussed in the text. The crossover region between the two telomeres is indicated by a cross. B, *Bgl*I; Ba, *Bam*HI; Bg, *Bgl*III; C, *Cl*aI; E, *Eco*RI; H, *Hind*III; K, *Kpn*I; M, *Msp*I; P, *Pst*I; Pv, *Pvu*II; S, *Sal*I; Sp, *Sph*I; Ss, *Sst*I.

Methods. The *T. brucei* AnTat 1.10D clone was obtained by selecting an AnTat 1.10 expressor among the heterotypes arising in the cloned AnTat 1.3A population, passaged in mice at 2–7-day intervals (ref. 28; see ref. 9 for a description of the AnTat 1.3A clone). AnTat 1.10 variants were detected after 7 days in mice, and the cloning procedure took a total of 24 days.

as revealed, among many other restriction digests, by the *Pst*I and *Sph*I digestion patterns shown in Fig. 3b. The *Pst*I digestion allows the analysis of the 5' environment of the gene (see map in Fig. 1). The latter is usually contained in a 9-kb *Pst*I fragment^{3,10}, which is reduced to 7.5 kb in AnTat 1.10D DNA (Fig. 3b, arrowhead); no additional sequence is visible in that clone. A 16-kb *Pst*I fragment (arrow) is present in AnTat 1.3A DNA and lost in 1.10D; this is caused by incomplete cutting in the 3' *Pst*I site of the *1.10* gene (bracketed in the map of Fig. 1)¹⁶. Such a lack of cleavage is only found in silent telomeric sequences, and probably results from a special form of DNA modification affecting some restriction sites^{11,16,17}. Complete digestion at such sites is characteristic of actively transcribed antigen genes^{11,16,17}, and this is found to be true for the *1.10*

gene in AnTat 1.10D DNA. The *Sph*I digestion shown in Fig. 3b allows the analysis of the 3' environment of the gene (see Fig. 1). The latter is present in a telomeric fragment (arrowhead), whose size varies in different clones through chromosome 'growth' and shrinking^{18,19}. In blots of AnTat 1.10D DNA, the band containing this fragment is associated with a smear (asterisk). Such a smear is characteristic of actively transcribed sequences, presumably because terminal deletions are much more frequent in active, 'open', chromatin¹⁹. This again is in keeping with the *1.10* gene being expressed in the AnTat 1.10D clone.

Conversely, the *1.3A* ex-ELC is no longer expressed in the AnTat 1.10D clone. Indeed, *1.3*-specific RNA could not be found in Northern blots of that clone (not shown). Furthermore, the inactivation of the *1.3A* ELC can be revealed using the same three criteria as discussed above for *1.10* gene activation. The *1.3A* ELC, hypersensitive to DNase I in AnTat 1.3A nuclei⁹, is no longer preferentially digested in AnTat 1.10D (Fig. 4a, arrowhead). Moreover, this sequence is modified in AnTat 1.10D, as revealed by the *Pst*I + *Sph*I digestion pattern shown in Fig. 4b: a 3' *Sph*I site (bracketed in the *1.3* restriction map in Fig. 1) is incompletely cut in the ex-ELC (arrow) in the AnTat 1.10D clone, while this site was completely cut in the ELC in the AnTat 1.3A clone¹⁶. Finally, the smear associated with the transcriptionally active *1.3A* ELC in clone AnTat 1.3A (Fig. 4b, asterisk) is not present in the AnTat 1.10D DNA.

The results presented here strongly suggest that telomeric antigen genes can be activated (or inactivated) by reciprocal recombination taking place in the barren regions, upstream from the genes. Indeed, the telomere exchange precisely involves the genes active in the two successive clones. However, despite the short time elapsed in cloning the trypanosome variants, we cannot exclude the possibility of intermediates in which the *1.10* gene is activated independently of the recombination.

This mechanism of antigen gene activation has not been described previously, although it has already been proposed as a possible model for gene activation without duplication^{3,6,20}. It has been calculated that as little as 14 base pairs (bp) of homology are sufficient for homologous recombination in mammalian cells, although the recombination frequency decreases sharply under 200 bp of homology²¹. Since the barren telomeric sequences are presumed to be largely homologous and present near many antigen genes on numerous chromosomes^{2,13,22,23}, it

Fig. 2 Exchange of the *1.3* and *1.10* antigen genes in chromosome-sized DNA of the AnTat 1.3A and 1.10D clones. Chromosome-sized molecules of two trypanosome clones (indicated at the top of a, b and c) were separated using pulse-field gradient gel electrophoresis^{2,29}. The gel was stained with ethidium bromide (a) and then blotted onto nitrocellulose. The filter was hybridized with ³²P-labelled AnTat 1.3 (b) or 1.10 (c) cDNA probe (see Fig. 1). Compared with the size estimations reported in ref. 12, slight corrections have been incorporated here, according to new size estimates with a ladder of λ DNA polymers as marker (A. Bernards, personal communication).

Fig. 3 The 1.10 gene is activated without duplication in the AnTat 1.10D clone. *a*, Kinetics of DNase I digestion in AnTat 1.10D nuclei, showing that the 1.10 gene (arrowhead) is selectively hydrolysed. Nuclei were isolated as described previously¹⁴, then incubated (0.5 mg DNA per ml) at 25 °C for 0, 30 s, 1, 2, 4, 8, 12, 16 and 30 min with DNase I (100 ng ml⁻¹), or 30 min without DNase I, from left to right lanes respectively. After *EcoRI* digestion and gel electrophoresis, the DNA was blotted onto nitrocellulose and hybridized with a 5' AnTat 1.10 probe (see Fig. 1). *b*, Restriction digests showing that, in the AnTat 1.10D clone, the 1.10 gene is not duplicated and bears two typical features of actively transcribed antigen genes (loss of telomeric DNA modification; terminal size heterogeneity). The *PstI* and *SphI* digestions generate fragments representing the 5' and 3' regions of the gene and its neighbourhood, respectively (see map in Fig. 1). The arrowhead and arrowed fragments are from the 1.10D gene, and are discussed in the text. The asterisk refers to the smear characteristic for active telomeres (see text).

is surprising that telomeric reciprocal recombination, such as the one described here, had not previously been detected, while, in contrast, gene conversion events are relatively frequent (reviewed in ref. 24). Why antigen gene switching by gene conversion is frequently observed, while reciprocal recombination events are not, is not known. In this context, it is perhaps significant that the reciprocal recombination event reported here has been detected between telomeres whose interaction was found, in a previous derivation, to lead to a very large conversion³, as if they were unable to convert each other at the 'usual' 5' end points of gene conversion, made up of 70-bp repeats^{13,22}. The reciprocal recombination observed here is apparently asymmetrical, since it was accompanied by a large deletion (~6 kb) in the 5' barren region of the 225-kb chromosome. This is consistent with the evidence^{13,22,23} that this region is at least partially made up of large arrays of 70-bp repeats, as recombination may thus take place at many possible sites. Size variation in the 5' barren region has also been observed linked to ELC insertion in the telomeric expression site^{3,4,7}.

As an example of genetic mechanisms involved in antigenic variation, expression of the AnTat 1.10 antigenic type is particularly interesting. This antigen is encoded by a telomeric gene, belonging to the AnTat 1.1 multigene family¹⁰, which can be transcribed following either of the two different gene activation procedures described to date. Indeed, this gene was found to be activated by ELC synthesis (that is, gene conversion) in several clones (ref. 10 and E.P., unpublished results), although the extent of the conversion appeared different in each clone, from about 2 to 3.5 kb. On the other hand, the same sequence was activated *in situ*, without duplication or chromosomal translocation, in the AnTat 1.1C clone³. In this case, it was also (subsequently ?) partially converted into an AnTat 1.1 antigen-coding sequence. Finally, the present study has found that it is expressed following telomeric reciprocal recombination. There are thus, for the same gene, many mechanisms of activation. These results suggest that, as in yeast²⁵, the telomeres in trypanosomes may be 'hotspots' of multiple rearrangement processes. The high frequency of genetic exchange in telomeres may be due to both the presence of repeated sequences and single-strand nicks, and the close contact between telomeres in mitosis²⁶. These rearrangements could sometimes generate newly func-

Fig. 4 The 1.3A ELC is conserved, but inactive, in the AnTat 1.10D clone. *a*, Kinetics of DNase I digestion in AnTat 1.10D nuclei, showing that the 1.3A ex-ELC (arrowhead) is no longer selectively hydrolysed. The order is the same as for Fig. 3a, except that the digestion was by *PstI*, and hybridization with the AnTat 1.3 probe. *b*, Restriction digests showing that, in the AnTat 1.10D clone, the 1.3A ex-ELC no longer exhibits the characteristic features of an actively transcribed telomeric sequence (namely a terminal smear and the absence of 3' restriction site polymorphism; see text). The *PstI* digestion allows the identification of the fragment extending to the telomere end (see map in Fig. 1). In AnTat 1.10D DNA, it is no longer associated with a smear, as it was in AnTat 1.3A DNA (asterisk). The *PstI* + *SphI* digestion reveals a fragment (arrow) due to a modification in the 3' *SphI* site of the 1.3A ex-ELC in AnTat 1.10D DNA; this polymorphism was not detected for the 1.3A ELC. Arrowheads indicate AnTat 1.3 gene-containing fragments.

tional antigen genes whose expression may be selected provided that it ensures adequate antigenic variation.

We thank Professor P. Borst for allowing us to use the pulse-field gradient gel electrophoresis apparatus in his laboratory, A. W. C. A. Cornelissen for technical advice and N. Murphy for discussion and valuable comments on the manuscript. This work was supported by grants from the Commission of the European Communities (TSD-M-023-B(RS)), from the 'Fonds de la Recherche Scientifique Médicale' (FRSM, conv. 3.9003.84), from the ILRAD/Belgian Research Centres Agreement for Collaborative Research (Nairobi), and by an IRSIA and a short-term EMBO fellowship to M.G.

LEICESTER POLYTECHNIC

School of Life Sciences

POST-DOCTORAL
SCIENTIST

Applications are invited from post-doctoral scientists to work with Professor M C Elliott's Plant Cell Biochemistry Group in genetic engineering of plant cells in suspension culture. Experience of genetic manipulation techniques and protein chemistry will be an advantage but is not essential.

The post is available for at least two years from the 1 October 1985 or as soon as thereafter as possible. Salary will be in the range of £7,548-9,348 per annum (under review).

Application forms and further particulars may be obtained from: the Personnel Officer, Leicester Polytechnic, PO Box 143, Leicester LE1 9BH.

Closing date: 22nd August, 1985.

MAITRE ASSISTANT

à charge complète, comprenant la participation aux enseignements pratiques de biologie animale et de génétique moléculaire. Le titulaire aura une activité de recherche au sein d'un groupe travaillant sur la régulation hormonale de l'expression génétique.

Les candidatures (avec curriculum vitae, 3 références, liste de publications et un tiré-à-part des 3 publications les plus significatives) sont à adresser, avant le 30 septembre 1985, au Prof. Walter WAHLI, Institut de Biologie animale, Bâtiment de Biologie, CH-1015 LAUSANNE (Suisse). (W2097)A

Clinical Research Associates

Gastroenterology, Respiratory, Cardiovascular,
Dermatology and Antibiotics

Greenford, Middx.

Glaxo Group is one of the world's leading and most successful pharmaceutical companies. The Medical Marketing Division of Glaxo Pharmaceuticals Limited conducts clinical research, is engaged in product development and provides medical services to the Glaxo Group of Companies on an international basis.

We are currently seeking Clinical Research Associates to join our Clinical Research Division based at Greenford. The work of the Division includes registration trials worldwide and trials of international marketing importance on new therapeutic indications for existing pharmaceutical compounds and new formulations.

The successful applicants will be responsible for designing, organising and monitoring clinical trials (Phases 3 and 4) in the above areas. Travel, both in the United Kingdom and overseas, is a necessary part of the job and a company car will be provided.

Candidates should possess a PhD or equivalent post graduate experience in a relevant scientific discipline. Previous experience with clinical trials is desirable but not essential. The ability to communicate effectively, both verbally and in writing is essential.

Excellent conditions of employment include attractive salary, company bonus scheme, 5 weeks' holiday, non-contributory pension scheme, sports and social facilities, and generous relocation assistance where appropriate.

Please write or telephone for an application form to Mr. I Campbell, Senior Personnel Officer,

(7302)A

Glaxo Pharmaceuticals LIMITED

891/995 Greenford Road, Greenford, Middlesex, UB6 0HE. Tel: 01-422 3434 ext. 2324 quoting ref. IC/818.

Head of the Institute's Standards Processing Section

The Institute is responsible for the standardisation and control of biological substances used in human medicine and is a major WHO International Laboratory for Biological Standards.

The Standards Processing section, presently situated at the National Institute for Medical Research at Mill Hill, undertakes the production, custody and distribution throughout the world of all biological standards prepared at NIBSC. These include a wide range of World Health Organisation International Standards, British Standards and Reference Preparations, Standards for use by the European community and preparations for use in research.

The Institute will be moving to new purpose-built laboratories under construction in South Mimms, Hertfordshire, which it is projected will be completed in August 1986, and the laboratories will include excellent accommodation for the Standards Processing Section.

The Head of the Section will be responsible for management of the Section's programme of work on the preparation of standards and will be expected to undertake a programme of research in an area relevant to biological standardisation. The position requires extensive liaison with scientists in other departments of the Institute and elsewhere.

Applicants should have a PhD or equivalent in an appropriate discipline, and a successful record of laboratory management and/or biological research. Experience in processing and freeze drying of potentially unstable materials, for example in the pharmaceutical industry, would be an advantage, as would a record of research relevant to an aspect of biological standardisation.

Salary, depending on qualifications and experience, will be on an appropriate scale lying between £15,368 and £24,880 per annum, inclusive.

Applications with full details should be made to the Director, NIBSC, Holly Hill, Hampstead, London NW3 6RB. Further details may be obtained from the Personnel Officer.

Closing date for applications will be 6th September '85.
(7357)A

NIBSC

National Institute for Biological Standards and Control

YALE UNIVERSITY POSTDOCTORAL RESEARCH FELLOW

A postdoctoral research position is available immediately for study of the molecular biology of cell surface receptors. Background in molecular genetics and/or nucleic acid biochemistry is required. Opportunity to apply recombinant DNA techniques to the solution of problems in cell biology as a member of a multi-disciplinary team investigating the structure and function of cell surface receptors for polypeptide growth factors and biogenic amines. Salary will range from \$16,000 to \$22,000 commensurate with years of relevant postdoctoral experience.

Applicants should send curriculum vitae, a statement of relevant experience and the names of three references to Dr John P Perkins, Department of Pharmacology, Yale University School of Medicine, 333 Cedar Street, New Haven, CT 06510. (NW117)A

STATE OF KUWAIT UNIVERSITY OF KUWAIT

Applications are invited for the post of
**Lecturers (Assistant Professors),
Assistant Professors
(Associate Professors) and
Professors (Full Professors)**

IN THE DEPARTMENT OF ZOOLOGY — Faculty of Science, for the second semester of the academic year 1985/86 tenable for 1st February, 1986, in accordance with the following:

- 1 — All applicants must hold Ph.D. Degree or its equivalent from a recognized University.
- 2 — The fields should be in Genetics.
- 3 — No applications will be considered from those who are not holders of

Ph.D. Degree at time of application. Only applications for vacancies advertised, will be considered.

Application together with a copy non-returned of the academic qualifications and the candidate's publications should be sent by registered post directly to the Department of Administrative Affairs, Kuwait University, P.O. Box 5969, Safat, Kuwait, not later than 30th October, 1985.

Selected candidates will be called for interview before final decision of appointment.
(W2090)A

DIRECTOR

CANCER RESEARCH CENTER OF HAWAII

The Cancer Research Centre is an organized research unit of the University of Hawaii, housed in its own new building adjacent to the Queen's Medical Center in downtown Honolulu. The Director is responsible for providing executive leadership, direction and management for the research and administrative affairs of the CRCH, which consists of five programs: (1) Basic Science, (2) Clinical Science, (3) Epidemiology, (4) Data Resources, and (5) Cancer Control. The Director must also develop the coordinate productive relationships within the University of Hawaii, the State of Hawaii, federal and local agencies involved in cancer research, the medical community and the lay public. The total budget is nearly \$4 million including about \$900,000 from State of Hawaii general funds.

Candidates should have: an earned doctorate degree, MD or PhD; a record of demonstrated leadership and administrative ability; national and international recognition in cancer research; experience in working with external agencies that support cancer research; and a record of successful grant procurement and research achievement.

Salary is negotiable depending on qualifications and experience. The Directorship is non-tenurable, but it is expected that the selectee will qualify for early tenure in a related academic department or research institute.

To apply send current resume and the names, addresses and telephone numbers of at least five (5) references to Robert L Pecsok, Dean of Natural Sciences, 235 Bilger Hall, 2545 The Mall, University of Hawaii, Honolulu, HI 96822. Telephone: (808) 948-6451.

Closing date is August 29 or later if position has not been filled.

The University of Hawaii is an Equal Opportunity/Affirmative Action Employer

(NW127)A

Geologist/Senior Geologist

You will join a multi-disciplinary team including stratigraphers, geophysicists and computing geologists involved with regional geological and plate tectonic studies of areas of current exploration interest. Your work will include applied research into global plate tectonics and palaeogeography as an aid to developing future exploration strategies.

You should have a first or 2.i degree in Geology/Earth Sciences, a Ph.D in an appropriate aspect of Earth Science, and a minimum of 2 years' post-doctoral research or exploration experience. A proven ability to synthesise diverse kinds of geological information

is essential.

An attractive remuneration package includes a non-contributory pension scheme, subsidised restaurant, on-site sports and social facilities and relocation assistance, where appropriate.

Please telephone for an application form or write enclosing a c.v., **quoting reference SR 2624**, to: Anne Sheppard, The British Petroleum Company plc, BP Research Centre, Chertsey Road, Sunbury-on-Thames, Middlesex TW16 7LN. Tel: Sunbury-on-Thames (09327) 62028.

BP is an equal opportunity employer.

(7367)A

MOLECULAR BIOLOGY POST-DOCTORAL SCIENTIST

Celltech's Molecular Immunology group has an established interest in the expression of recombinant immunoglobulin genes. We are now increasing our effort in using these techniques to engineer therapeutic antibodies.

As part of this expanding programme, we are looking for a molecular biologist, either with post-doctoral experience or expecting soon to finish a Ph.D. This position demands a creative approach to engineering novel molecules and an interest in a range of areas, including molecular biology, immunology, and clinical testing of potential products.

You will work in a small friendly team, gaining valuable experience, with plenty of opportunity for interaction with Celltech's many research groups. Celltech pays competitive salaries commensurate with experience and qualifications.

Please send a full c.v. to Jane Walley, Personnel Officer, Celltech Limited, 244 Bath Road, Slough, Berks SL1 4DY quoting reference number 268.

(7296)A

FACULTY IN COMPLEX CARBOHYDRATE SCIENCE

The UNIVERSITY OF GEORGIA is establishing, in October 1985, the COMPLEX CARBOHYDRATE RESEARCH CENTER. The CCRC is particularly well-equipped and well-organized for collaborative and interdisciplinary research. The CCRC will start with 5 faculty and about 25 members and is projected to increase in 3 or 4 years to about 15 faculty and 100 members. The CCRC is initiating a search for additional faculty in regular tenure-track positions. Rank and salary will be dependent on experience. Applications are requested in all areas of complex carbohydrate science, although the CCRC is particularly interested in applicants with expertise in:

CHEMICAL SYNTHESIS
CONFORMATION ANALYSIS (COMPUTER MODELING)
MOLECULAR BIOLOGY (RECOMBINANT GENETICS)
ENZYMOLGY (ENDOGLYCANASES)
BIOASSAY (OF CARBOHYDRATES WITH REGULATORY PROPERTIES)
IMMUNOCHEMISTRY

Applications will be accepted for an indefinite period, although evaluations of those applications received will begin November 1, 1985. Applications should be sent to:

Dr Peter Albershiem, Director, Complex Carbohydrate Research Center, Richard B. Russell Agricultural Research Center, P.O. Box 5677, Athens, Georgia 30613, U.S.A.

The University of Georgia is an Affirmative Action/Equal Opportunity Employer. (NW124)A

sera-lab SERA-LAB LIMITED

This small successful biotechnology company requires a

Monoclonalist / Tissue culturist

to run an established monoclonal antibody laboratory along production lines. Technical assistance is available. The successful applicant will probably be at degree or equivalent level although first-hand experience in hybridoma technology is equally important. Experience in immunochemistry would be advantageous.

Pleasantly situated in rural Sussex yet near London, this permanent appointment is regarded an integral part of company structure. Salary by arrangement.

Applications to include C.V. plus names, addresses and telephone numbers of three referees to Dr. R.W. Tindle, Sera-Lab Limited, Crawley Down, West Sussex. RH10 4FF. Telephone Number 0342-716-366. (7342)A

MAMMALIAN CELL BIOLOGIST

A Ph.D. with academic or industrial post-doctoral experience is sought for a position in a multidisciplinary group studying high density mammalian cell culture in the Biotechnology Laboratory of Central Research at The Dow Chemical Company. The successful candidate will have experience in handling multiple cell lines and associated analytical techniques and will have responsibility for the planning, organization and execution of a high priority program in the development of optimal culture conditions.

For further information, please contact:

Dr. Kerr Anderson
Central Research
Biotechnology Laboratory
1701 Building
The Dow Chemical Company
Midland, MI 48674

(NW121)A

POSTDOCTORAL POSITION

Immediate opening for a molecular biophysicist to work on the structural, dynamic and thermodynamic characterisation of nucleic acid junctions (Nature 305, p 829). Physical and biochemical studies are currently underway in a laboratory equipped with an automatic oligonucleotide synthesis capability. Requirements are a PhD in Chemistry, Biochemistry, Molecular Biology or a related area. Salary range \$18-23,000.

Send vitae and names of 3 references to Dr Nadrian C Seeman, Department of Biological Sciences, SUNY/Albany, Albany, NY 12222. SUNYA is an Affirmative Action/Equal Opportunity Employer. Applications from minority persons, women, handicapped persons, and Viet Nam veterans are especially welcome. (NW112)A

FACULTY POSITIONS IN BIOCHEMICAL GENETICS

The Departments of Biochemistry and Medical Genetics, School of Medicine, Oregon Health Sciences University (OHSU), invite applications for two tenure track faculty positions at the assistant or associate professor level. We are particularly interested in candidates who are working in the following general areas:

- 1 Protein structure and function, or
- 2 Eukaryotic molecular genetics; somatic cell genetics.

Applicants should have a doctoral degree with at least 3 years of post-doctoral experience, and each is expected to carry out an independent active research program. Teaching responsibilities include participation in courses in Biochemistry, genetics, and developmental biology for medical students and PhD candidates. Compensation will depend on professional experience and will conform with institutional standards. Potential for collaboration exists with other departments of the University in a growing research environment that includes the Oregon Regional Primate Research Center, the Portland Shriners Hospital Research Unit and a new Institute for Advanced Biomedical Research. Co-chairmen of the search committee are Richard T. Jones, Chair, Department of Medical Genetics. Applicants should send curriculum vitae, bibliography, reprints of representative papers, a summary of career goals and research plans, and names of three references to: Biochemical Genetics Search Committee, School of Medicine, L224, Oregon Health Sciences University, 3181 Southwest Sam Jackson Park Road, Portland, Oregon 97201. All applications received by September 15, 1985 will be considered. Women and minority candidates are especially invited to apply. OHSU is an Equal Opportunity/Affirmative Action Employer. (NW132)A

THE UNIVERSITY OF NEW ENGLAND
Equal Opportunity is University Policy
DEPARTMENT OF BIOCHEMISTRY, MICROBIOLOGY & NUTRITION
Lecturer in Human Nutrition

The appointee should hold a postgraduate degree in the field of human nutrition and preferably a qualification in dietetics as well.

The appointee will be expected to teach and develop courses in human nutrition, to supervise honours and postgraduate students and carry out research

The Department is well equipped for research in a number of areas, including whole body calorimetry and energy metabolism of man

Informal enquiries to Associate Professor R.B. Cumming (067) 73-2510 or ISD (61 67 73-2510).

SALARY:	A\$26,236 — A\$34,467 per annum
CLOSING DATE:	30th August 1985
POSITION NO:	517

The appointment will be to the permanent staff but the University reserves the right to make the appointment probationary where it considers this appropriate.

Other conditions include superannuation, assistance with travel and removal expenses and with buying or building a house in Armidale

Applications including the names and addresses of three referees and stating the position number should be sent to the Staff Officer, University of New England, Armidale N.S.W. 2351, prior to the closing date. Applicants should forward a copy of this advertisement to their referees and ask them to send their reports direct to the Staff Officer, Mr B.G. Turner, marking their envelopes 'Private and Confidential' and quoting the position number, before the above closing date so as to expedite the appointment process. (W2095)A

**POST DOCTORAL
RESEARCH POSITION**

available immediately for a minimum of three years to study Cell Surface Phenotype, DNA Content and Kinetic Properties of Lymphoma cells using the flow cytometer as the main analytical instrument. Independent research in related areas such as Lymphoma Growth Regulation and Differentiation, and Anti Idiotypic Antibody Production will be encouraged.

At least two years experience in cell biology and/or cellular immunology is required. Stipend commensurate with experience.

Please send a CV and names of references to: Paul C. Braylan, M.D., Professor, Department of Pathology, Box J-275, JHMHC College of Medicine, University of Florida, Gainesville, Florida 32610. (NW130)A

**M.R.C. CLINICAL RESEARCH CENTRE
(NORTHWICK PARK HOSPITAL)
WATFORD ROAD, HARROW
MIDDXX, HA1 3UJ**

NON-CLINICAL SCIENTIST

Applications are invited from biochemists with an interest in genetics for a postdoctoral position in the division of immunochemical genetics for investigations on glycosyltransferase enzymes involved in the biosynthesis of carbohydrate antigens.

The project involves purification of the relevant enzymes and a study of their properties and structure in preparation for molecular genetic studies on the relevant genes. Applicants should have experience in enzyme purification and protein chemistry.

The appointment is for 3 years starting as soon as possible. The salary will depend on qualifications and experience and will be within the range £8,920 — £14,925 pa plus £1,233 pa London Weighting.

Applications together with curriculum vitae, research experience and the names of two professional referees should be sent to Dr Winifred M Watkins, Division of Immunochemical Genetics not later than 29th August 1985 (172071)A

CSIRO
AUSTRALIA
**APPLIED ELECTRON
MICROSCOPY**

\$26,001 — \$38,243

**DIVISION OF CHEMICAL PHYSICS
CLAYTON VIC**

CSIRO conducts scientific and technological research in laboratories located throughout Australia and employs about 7,500 staff, of whom some 2,900 are professional scientists. The Organization's research activities are grouped into five Institutes: Animal and Food Sciences, Biological Resources, Energy and Earth Resources, Industrial Technology and Physical Sciences. The CSIRO Division of Chemical Physics is a member of the Institute of Physical Sciences.

GENERAL: The Division of Chemical Physics is principally located at Clayton, Victoria, with a smaller unit at the Lucas Heights Research Laboratories, Lucas Heights, New South Wales. The Division prosecutes a broad program of research in chemical physics, using fundamental methods. Presently there are twelve sections: atomic, mass and molecular spectroscopy, applied optics, electron microscopy, electron diffraction, X-ray diffraction, computing, theoretical physics, crystal defect physics, radiation effects (including radiation chemistry and ion implantation), solid state science, surface science, and instruments and engineering services. Divisional research objectives are both fundamental and applied.

BACKGROUND: Research programme aims and objectives at the Division of Chemical Physics are constantly subject to reassessment. Two sections — electron microscopy and electron diffraction — will shortly be consolidated into a single group. All research and development of the electron microscope as an instrument 'per se' will be phased out and, while some fundamental research into electron scattering and associated problems will continue, there will be a growing emphasis on applying the techniques of both transmission and scanning electron microscopes to materials problems specific to Australian Industry.

DUTIES: The Division currently conducts research into the surface and bulk properties of materials using electron microscopy and diffraction. The appointee will use these techniques to investigate how ion implantation and similar methods modify, or "tailor" such properties. Access to modern high speed computing facilities for the quantitative analysis of high resolution electron micrographs is available. The appointee will also participate in a broadening of the present ion implantation and surface modification programs to include metals, alloys, insulators, glasses, polymers and ceramics. High resolution electron microscopy as well as conventional diffraction and scanning electron microscopy techniques will be used in materials analysis and characterisation. Encouragement will be given to develop micro-analytical techniques based on dynamical effects which occur in the inelastic scattering of fast electrons.

QUALIFICATIONS: A PhD degree or equivalent, with experience in modern electron microscopy and diffraction techniques. A background in Metallurgy and Materials Science will be an advantage.

Above all, the successful candidate will have a positive and aggressive attitude towards identification and solution, using a variety of electron scattering techniques, of the materials problems of Australian industry.

TENURE: Indefinite with Australian Government superannuation benefits available.

APPLICATIONS: Stating relevant personal particulars, including details of qualifications and experience, the names of at least two professional referees and quoting reference No A1663, should be directed to.

The Chief
 CSIRO Division of Chemical Physics
 PO Box 160
 CLAYTON VIC 3168

CSIRO IS AN EQUAL OPPORTUNITY EMPLOYER

(W2107)A

National Physical Laboratory

Theoretical Physicist

A small theoretical studies group is being established within this Laboratory to advance its understanding of the interaction of radiation with matter and to apply theoretical methods in support of the standards programme

A theoretical physicist is required to join this group to work on problems associated with high energy photon and electron absorbed dose determinations and conservation of exposure measurements to absorbed dose. You will be expected to initiate and manage projects within the overall framework of the branch programme and in collaboration with other groups. You will have access to the Laboratory's extensive irradiation and computing facilities

You must have a good honours degree or equivalent qualification in an appropriate subject whilst a higher degree in radiation physics is desirable. You should also have a proven ability to tackle complex theoretical problems at post-doctoral level

Salary: £12,900-£17,005 (including £545 Outer London Weighting) with starting salary according to qualifications and experience.

RELOCATION EXPENSES UP TO £5000 MAY BE AVAILABLE.

For further details and an application form (to be returned by 30 August 1985) write to Civil Service Commission, Alencon Link, Basingstoke, Hants RG21 1JB, or telephone Basingstoke (0256) 468551 (answering service operates outside office hours).

MOLECULAR GENETICIST

\$26,001 — \$38,243

DIVISION OF MOLECULAR BIOLOGY
NORTH RYDE NSW

CSIRO conducts scientific and technological research in laboratories located throughout Australia and employs about 7,500 staff, of whom some 2,900 are professional scientists. The Organization's research activities are grouped into five Institutes: Animal and Food Sciences, Biological Resources, Energy and Earth Resources, Industrial Technology and Physical Sciences. The CSIRO Division of Molecular Biology is a member of the Institute of Animal and Food Sciences.

GENERAL: The Division of Molecular Biology conducts scientific research in molecular genetics and cell biology. It has a staff of approximately 100. Programs are divided into: Tissue Growth and Development, DNA Maintenance and Modification and Gene Technology. It is situated in Sydney, at North Ryde, close to Macquarie University and major biotechnology companies.

DUTIES: As a member of a team working on several aspects of DNA maintenance and modification, the appointee will conduct a program of research on the mechanisms of mutagenesis and antimutagenesis in bacteria. This work will be directed towards understanding the role cellular processes play in the modulation by certain chemical agents of mutagenic activity.

QUALIFICATIONS: A PhD degree with training in microbial genetics, supported by established research ability, preferably with mutagenicity assay systems in *Escherichia coli* and *Salmonella typhimurium*. Experience in manipulating genes in bacteria using conjugation transduction and transposon techniques, experience in genetic toxicology and/or familiarity with techniques used in detecting DNA-damage and mutagenicity would be of considerable advantage.

TENURE: Indefinite with Australian Government superannuation benefits available.

Senior Micropalaeontologist

A challenging career in biostratigraphy

This is an opportunity for a micropalaeontologist with at least 5 years' post-doctoral experience in industry, government or academia.

Your responsibilities will be many and varied. They will include analysing individual wells as they are being drilled, sometimes at the well site; analysing groups of wells from individual oil fields or entire petroleum provinces to establish ages, correlations and palaeoenvironments. These studies can help to improve seismic interpretations and our understanding of reservoir geometry.

There are also opportunities for involvement in multi-disciplinary groups working on operational problems or on ad hoc research and development.

Our research is directed to building the industrial biostratigraphy of tomorrow and skills and interests in computer manipulation of biostratigraphic data

will, therefore, be an advantage.

You will work with BP's explorers worldwide, and you can expect short or long term postings to operating centres such as Aberdeen, Canton or Holland at some time in your career. To help your interactions with exploration geologists, we offer a comprehensive training programme.

An attractive salary package is offered together with a non-contributory pension scheme. Excellent benefits include assistance with relocation, where appropriate.

Please write or telephone for an application form, quoting reference **SR 2629**, to: Anne Sheppard, BP Research Centre, Chertsey Road, Sunbury-on-Thames, Middx. TW16 7LN. Tel: Sunbury-on-Thames (09327) 62028.

DIVISION OF FOREST RESEARCH
TROPICAL RAINFOREST
RESEARCH CENTRE
ATHERTON QLD

CSIRO conducts scientific and technological research in laboratories located throughout Australia and employs about 7,500 staff, of whom some 2,900 are professional scientists. The Organization's research activities are grouped into five Institutes: Animal and Food Sciences, Biological Resources, Energy and Earth Resources, Industrial Technology and Physical Sciences. The CSIRO Division of Forest Research is a member of the Institute of Biological Resources.

A highly experienced scientist is required to lead expanding research activities at the CSIRO Tropical Rainforest Research Centre, Atherton, Queensland and co-ordinate associated projects by scientists based at other locations.

Rainforests in Northern Queensland extend in a discontinuous belt for about 500 km along the eastern coast from just north of Townsville to Cooktown. They occur on a wide range of soil types from sea level to over 1500 m elevation. Rainfall varies from more than 4000 mm to less than 1000 mm some 100 km inland. Atherton itself is at an elevation of 750 m, has a mean temperature of 20°C and an average rainfall of 1400 mm.

Research staff at the CSIRO Laboratory in Atherton are from the Division of Forest Research (6 scientists), Wildlife and Rangelands Research (1 scientist) and Plant Industry (1 scientist). Total staff complement at present is 22. The Headquarters of the *Division of Forest Research* are at Canberra ACT; research is also undertaken from laboratories in Perth, Mt Gambier, Hobart and Brisbane, as well as Atherton. Research in progress at Atherton is in the programs Soils and Nutrition, Genetic Resources and Breeding Strategy, and Ecophysiology. The Division of Plant Industry maintains at Atherton, as part of the Australian National Herbarium, a major collection of rainforest specimens. The *Divi-*

sion of Wildlife and Rangelands Research work is on the response of animal populations to changes in the forest, and on the role of vertebrates in regeneration and succession. It is expected that, with the new developments, total staff involved in the tropical rainforest program, at Atherton and elsewhere, will grow to about 40.

DUTIES: The appointee will lead a major new thrust in rainforest research and will have a high level of responsibility for planning, development, co-ordination and oversight of the overall program. The work will be done by the staff at Atherton and by groups based elsewhere, including other CSIRO Divisions. These are likely to include modellers and ecologists from the Division of Water and Land Resources, wildlife ecologists from the Division of Wildlife and Rangelands Research, plant taxonomists from the Division of Plant Industry, insect taxonomists from the Division of Entomology; and geneticists at the Division of Forest Research. The leader will also be responsible for the efficient operation of the Atherton laboratory including personnel and financial management, for developing a program of visiting scientists and related seminars and for fostering interaction with agencies such as the Queensland Forest Department, Queensland National Parks and Wildlife, and University groups.

While the initial focus will be on tropical rainforests, the interests could eventually extend to other tropical forests. CSIRO also has a program on open forests in the wet/dry tropics based at Darwin, under separate leadership.

The appointee will also initiate and be responsible for his/her own research programs within the tropical rainforest field.

QUALIFICATIONS: A PhD degree or equivalent qualifications in a relevant field, together with a record of substantial research experience and achievement. Demonstrated capacity in the management of research work and staff is essential. Appointment at a higher level would be considered for a suitably qualified applicant.

TENURE: Indefinite with Australian Government superannuation benefits available.

APPLICATIONS: Stating relevant personal particulars, including details of qualifications and experience, the names of at least two professional referees and quoting reference No. A2739, should be directed to:

ELECTRICAL ENGINEER/COMPUTER SCIENTIST
THE UNIVERSITY OF GEORGIA

is establishing in October 1985, the Complex Carbohydrate Research Center. The CCRC is particularly well-equipped and well-organized for collaborative research. The CCRC will start with five faculty and about 25 members and is projected to increase in 3 or 4 years to about 15 faculty and 100 members. The CCRC will be equipped with nuclear magnetic resonance spectrometers, several mass spectrometers, and many micro and mini-computers, which will interface with the University's Cyber super-computer. The CCRC wishes to hire an individual with experience in testing and tuning high frequency measuring instruments (eg ultra-high field NMR and high-mass mass spectrometry) thorough knowledge of analog and digital electronic techniques and experience in programming (in assembly as well as higher level languages) using micro-, mini-, and/or super-mini computers. The individual will use computers for such laboratory needs as system control and digital signal processing, eg fast Fourier processing. This individual's primary responsibility will be to maintain (and modify) the laboratory's instruments. The successful applicant will have an interest in interacting with biologists and chemists. Annual salary (about \$40,000) will depend on training and experience. Applications will be accepted for an indefinite period, although evaluation of those applications received will begin by October 1, 1985. Applications should be sent to:

Dr Peter Albersheim, Director, Complex Carbohydrate Research Center, Richard B Russell Agricultural Research Center, PO Box 5677, Athens, Georgia 30613, USA.

The University of Georgia is an Affirmative Action/Equal Opportunity Employer (NW125)A

Faculty Positions available at Assistant, Associate and Full Professor levels in the newly established Center for Biotechnology. The Center consists of three divisions: (i) Hybridoma Technology; (ii) Recombinant DNA Technology and (iii) Cellular and Molecular Neurobiology.

Applicants should have research background in one of these areas. Experience and interest in biotechnological applications are desirable but not required.

Please send résumé, a brief description of research experience and future goals, and names of several references to:

CANADA DIRECTOR OF RESEARCH

The Hospital for Sick Children, Toronto, Canada is seeking a leading scientist, M.D. or Ph.D., as Director of its Research Institute.

The Hospital for Sick Children is the largest paediatric hospital in North America and is the Department of Paediatrics, Faculty of Medicine of the University of Toronto. Located in central Toronto in close proximity to the University and other major teaching hospitals. Medical Staff and Investigators hold appointments at the University.

The Research Institute is a broadly based organization with an international reputation in medical research. A staff of 743 includes 70 full-time and 80 part-time investigators, 143 post and predoctoral fellows and full support services with a budget of \$25 million per annum.

Evidence of leadership capabilities and demonstrated excellence in a specific area of research are essential requirements for this position.

Salary and benefit program are negotiable.

Nominations or applications which should include a curriculum vitae should be sent to:

Mr. J. Douglas Snedden
President
The Hospital for Sick
Children
555 University Avenue
Toronto, Ontario, Canada

SCIENTIST – DIVISION OF BLOOD PRODUCTS

£9,213 - £12,438

We require a scientist with a PhD in biochemistry, pharmacology, or the biological sciences, preferably with some post doctoral experience, to work in the Division of Blood Products.

The person appointed will be responsible for quality control tests on certain blood products. There is considerable scope for individual and collaborative research within the field of haemostasis, both locally and internationally.

The appointment is for 5 years, in the first instance. Salary is on a scale of £9,213 - £12,438 inclusive, dependent on age, qualifications, and experience.

For further details, please contact the Personnel Office, NIBSC, Holly Hill, Hampstead, London NW3 6RB. Tel. No. 01-435-2232. (7358)A

NOVO

Organic Chemist Pharmaceutical Research

Due to expansion of our pharmaceutical research, our Laboratory of Medicinal Chemistry has an opening for an organic chemist, ideally with post-doctoral experience within pharmaceutical or biochemical research.

The candidate must have good practical experience in synthetic organic chemistry, or have worked with isolation and identification of natural products, and be familiar with analytical and purification techniques used in organic chemistry.

The applicant will join an independently working research group consisting of chemists, biochemists, and pharmacologists.

The applicant is expected to engage her/himself with energy and enthusiasm in solving problems concerning her/his research and drug development.

Finally the applicant will be expected to participate in a continual development of a progressive and creative research setting which will give her/him the opportunity for a personal and professional development.

Our main research interest are focused on peptide hormones, neurotropics and new drugs in the inflammation area.

Applications marked "Organic Chemist" should be addressed to Personnel Dept. by 15th of September, 1985.

For further information please contact Claus Bræstrup, phone 45 2 98 23 33, ext. 2106 or B.F. Lundt; phone 45 2 98 23 33, ext. 2213.

Novo Allé
DK-2880 Bagsvaerd
Copenhagen

Novo is a Danish pharmaceutical and biochemical Group whose products — primarily insulin and enzymes for industrial uses — are marketed throughout the world. The Novo Group has subsidiaries and information offices in 25 countries and employs approximately 4,600 people, of which approx. 900 in research and development, quality control and technological services. (W2114)A

Senior Stratigrapher/ Biostratigrapher

**"to work in support of
exploration and production"**

You will join a multi-disciplinary research group, whose goal is to develop new ideas and approaches to improve BP's use of biostratigraphy in support of our exploration and production activities. Our aim is to widen the perspective of biostratigraphic thinking beyond the traditional dating of sediments and interpretation of their paleoenvironment.

Our research interests cover such diverse topics as:

- paleobathymetry for subsidence analysis
- sealevel and its role in developing sedimentary sequences
- sequence stratigraphy and the relation between microfossils and stratigraphic sequences
- quantitative methods in biostratigraphy to improve correlation
- paleobiogeography to improve regional biostratigraphy

This challenging post calls for an unusual blend of geological skills. You should have a PhD, 8 years' post-doctoral experience, preferably gained in the petroleum industry, together with experience in sedimentology, seismic stratigraphy and biostratigraphy. Familiarity with the use of computers is essential.

An attractive remuneration package includes a non-contributory pension scheme, subsidised restaurant, on-site sports and social facilities and relocation assistance, where appropriate.

Please telephone for an application form or write enclosing a c.v., quoting reference **SR 2628**, to: Anne Sheppard; The British Petroleum Company plc, BP Research Centre, Chertsey Road, Sunbury-on-Thames, Middlesex TW16 7LN. Tel: Sunbury-on-Thames (09327) 62028.

BP is an equal opportunity employer.

CANCER RESEARCH CAMPAIGN CELL BIOLOGIST

PhD graduate required for research into effects of ionizing radiations on the cellular and subcellular level. Candidates should be familiar with mammalian cell culture and preferably have experience of assays of DNA damage and repair. Experience of biochemical and molecular biological techniques desirable. Salary on MRC Grade II Scientist scale (max. £12,438 pa inc Londo weighting). Apply with full CV and names and addresses of two referees to: Administrator (5), CRC Gray Laboratory, Mount Vernon Hospital, Northwood, Middx. HA 2RN. (73121)A

ANALYTICAL CHEMIST/ BIOCHEMIST

Dista Products Limited is part of Eli Lilly and Company, a leading U.S. Manufacturer of Pharmaceutical, Veterinary and Agrochemical Products.

The Company wishes to appoint an Analytical Chemist or Biochemist for its Analytical Technical Services Group. This group undertakes a wide range of analytical work, largely non-routine, and is currently highly involved in supporting the biosynthetic production of polypeptides including human insulin.

Applications are invited from Chemists or Biochemists with several years' experience in analytical work. A prime requirement is a working knowledge of analytical techniques as applied to proteins/polypeptides, particularly HPLC, SEC, RIA and ELISA. A Postgraduate qualification is desirable but not essential.

The Company offers excellent career opportunities to suitably motivated employees and an attractive salary will be offered. Other Company benefits include a non-contributory pension plan, membership of BUPA and flexible working hours. Relocation assistance in appropriate cases will be given.

Please apply, in writing, outlining academic and career history to:

THE MEDICAL COLLEGE OF ST BARTHOLOMEW'S HOSPITAL DHSS DEPARTMENT OF TOXICOLOGY RESEARCH TECHNICIAN Salary Scale £6,822 - £9,180 incl

Applications are invited from technical staff, as well as recently qualified graduates, for this position to work on the biochemistry of the regulation of hepatic alpha-2u globulin synthesis.

The work will involve the techniques of cell culture, immunochemistry and molecular biology. Experience in these areas would be useful but is not essential since full training will be provided. The position is funded in the first instance by ICI PLC and will be for a period of one year.

Applications to: The Secretary, The Medical College of St Bartholomew's Hospital, West Smithfield, London EC1.
Closing date: 30 August 1985 (7362)A

CSIRO AUSTRALIA APPLIED/ COMPUTATIONAL MATHEMATICIAN

\$26,001 — \$38,243

DIVISION OF MATHEMATICS AND
STATISTICS
LINDFIELD NSW

CSIRO conducts scientific and technological research in laboratories located throughout Australia and employs about 7,500 staff, of whom some 2,900 are professional scientists. The Organization's research activities are grouped into five Institutes: Animal and Food Sciences, Biological Resources, Energy and Earth Resources, Industrial Technology and Physical Sciences. The CSIRO Division of Mathematics and Statistics is a member of the Institute of Physical Sciences.

The Division of Mathematics and Statistics has a staff of 95, including 72 professional scientists. The Division's Headquarters are at Canberra, and there are Regional Offices located at Melbourne, Sydney, Adelaide, Brisbane and Perth. Scientists of the Division provide advice on the statistical, mathematical and numerical aspects of research projects undertaken by scientists in other CSIRO Divisions, as well as conducting basic research in statistics and mathematics and working with Australian industry.

The Division has an active Applied and Computational Mathematics Program working on collaborative research projects with CSIRO Divisions in a variety of areas including manufacturing technology, oceanography, energy technology and applied physics. Members of the group are currently located in Canberra, Hobart, Melbourne and Sydney.

The appointee will be a member of the above Program and will be located in Lindfield and in addition to working on collaborative research projects with Sydney Divisions (including Applied Physics, Mineral Physics and Mineralogy and Radiophysics) will contribute to the basic research of some aspects of applied and computational mathematics, as well as to projects initiated with industry.

QUALIFICATIONS: A PhD degree or equivalent qualifications in a relevant branch of mathematics, together with a proven record of research and collaboration in relevant areas of mathematics. Expertise in the numerical solution of partial differential equations, numerical linear algebra and computational problem solving are particularly relevant. Familiarity with industrial applied mathematics and a commitment to the application of mathematics to practical and challenging industrial problems are also desirable.

TENURE: A term of 3 years, with the possibility of a further term. Australian Government superannuation benefits available.

APPLICATIONS: Stating relevant personal particulars, including details of qualifications and experience, the names of at least two professional referees and quoting reference No. M7743, should be directed to:

DIVISION OF MATHEMATICS AND STATISTICS

GLEN OSMOND SA

CSIRO conducts scientific and technological research in laboratories located throughout Australia and employs about 7,500 staff, of whom some 2,900 are professional scientists. The Organization's research activities are grouped into five Institutes: Animal and Food Sciences, Biological Resources, Energy and Earth Resources, Industrial Technology and Physical Sciences. The CSIRO Division of Mathematics and Statistics is a member of the Institute of Physical Sciences.

The Division of Mathematics and Statistics has a staff of 95, including 72 professional scientists. The Division's Headquarters are at Canberra, and there are Regional Offices located at Melbourne, Sydney, Adelaide, Brisbane and Perth. Scientists of the Division provide advice on the statistical, mathematical and numerical aspects of research projects undertaken by scientists in other CSIRO Divisions, as well as conducting basic research in statistics and mathematics and working with Australian industry.

The Division has a new program called Statistics in Earth and Space Science. Within this program there are sub-programs to pursue statistical methodology in Crop Research, Earth Sciences, the analysis of spatial data and time series analysis.

DUTIES: As a senior member of the Crop Research Sub-program, the appointee will initiate collaborative research projects with other scientists involved in conducting field trials and will supervise a research project investigating statistical methodology in the design and analysis of field trials with particular attention to nearest neighbour methods.

QUALIFICATIONS: A PhD degree or equivalent qualifications in statistics, together with a proven record of research and collaboration in the design and analysis of experiments. Expertise in incomplete block and nearest neighbour methodology associated with the design and analysis of field trials is particularly relevant. The appointee should also have a demonstrated ability to supervise research in applied statistics and a commitment to the application of statistics to practical and challenging problems in the biological sciences.

TENURE: A term of 3 years, with Australian Government superannuation benefits available.

APPLICATIONS: Stating relevant personal particulars, including details of qualifications and experience, the names of at least two professional referees and quoting reference No. M7742, should be directed to:

POST-DOCTORAL POSITION

available after 1 October

Cell biology-physiology-biochemistry laboratory studying isolated cardiac membrane channel proteins seeks

IMMUNOLOGIST OR PROTEIN BIOCHEMIST

with immunological experience for immunofluorescence and immunoelectron microscopic investigations. Applicant should have doctorate and experience with poly- and monoclonal antibody techniques.

Send curriculum vitae, description of research interests, references to: Dr. Ernest Page, Department of Medicine, BH Box 137, The University of Chicago, 5841 South Maryland Avenue, Chicago, Illinois 60637. Equal Opportunity/Affirmative Action Employer. (NW45)A

THE AUSTRALIAN NATIONAL UNIVERSITY

Applications are invited from suitable qualified men and women for appointment to the following position:

Faculty of Science

DEPARTMENT OF BOTANY LECTURER IN PLANT CELL BIOLOGY (FIXED TERM)

The appointee will contribute to teaching especially in second-year and third-year units in cell biology, may supervise honours and graduate students, will be expected and encouraged to conduct research, and to perform other administrative duties in the department. Applicants must have a broad interest in and knowledge of both biochemical and ultrastructural aspects of plant cell biology, should have relevant teaching experience and also should have engaged in productive research. The appointment is for the three years 1986-88 inclusive. The successful applicant will be expected to take up duty, if possible, in January 1986. Enquiries to the Head of Department (062)492866.

Closing date: 30 August 1985.
Ref: FS 18/7/1.

Conditions of appointment: Salary will be in accordance with qualifications and experience within the range: Lecturer \$A26,236 — \$34,467 pa.

Grants are provided towards travel and removal. Assistance towards housing is given to an appointee from outside Canberra. Eligible appointees will be required to join the Superannuation Scheme for Australian Universities. Maternity leave is available. The University reserves the right not to make an appointment or to make an appointment by invitation at any time. Applicants should quote the advertisement reference when requesting further particulars, and when submitting applications, which should be submitted to the Acting Registrar of the University, GPO Box 4, Canberra, ACT 2601, Australia. Further particulars also available from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

The University is an Equal Opportunity Employer. (W2103)A

THE UNIVERSITY OF NEW SOUTH WALES Sydney, Australia

LECTURER IN SCHOOL OF APPLIED GEOLOGY

(Tenure or Tenurable appointment)

(Ref: 1068)

A Lectureship in Geophysics will be available commencing January 1986. The successful applicant will be responsible for teaching and research in reflection and refraction seismic methods. Teaching will be at both undergraduate and postgraduate levels and will involve supervision of postgraduate research.

Applicants should have a PhD in Geophysics or equivalent research experience. A record of research ability and experience in reflection and refraction seismic methods is required. Preference will be given to candidates with experience in industry.

The School is dedicated to teaching and research in the application of fundamental geological and geophysical knowledge to problems of resource development. The appointee would be expected to maintain a similar attitude in his/her fields of interest.

Appointment will be either tenure or on the basis of a contract with provision for conversion to tenure.

Further information from Associate Professor P R Evans, Head of School, University of New South Wales, P O Box 1, Kensington NSW, Australia 2033 (tel: (02) 4268).

Applications close 20 September 1985.

Salary: \$A26,236 range \$A34,467. Commencing salary according to qualifications and experience.

For further information about conditions of appointment, method of application write to Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Equality of employment opportunity is University policy. (W2104).

POSTDOCTORAL RESEARCH FELLOW

with interest in tissue culture and application to the study of the inflammatory reaction, or

POSTDOCTORAL RESEARCH ASSOCIATE

with experience in the field.

Applications are invited for work to begin immediately. Salary based on MRC guidelines.

Send curriculum vitae and names of 2 referees to: Dr Henry Z Mo, Department of Pathology, Medical Sciences Building, University of Toronto, Toronto, Canada M5S 1A5.

RESEARCH ASSISTANT IN NEUROPHYSIOLOGY AND BEHAVIOUR

Applications are invited for this post to work on the activity of single neurones in visual and taste information processing in the primate brain. The post is appropriate for a postdoctoral scientist with experience in neurophysiology. The salary is on the RS 1A salary scale, £7,520 to £11,250.

Applications/enquiries in writing to Dr E T Rolls, University of Oxford, Department of Experimental Psychology, South Parks

UNIVERSITY OF

RESEARCH ASSOCIATE

Applications are invited for an MRC funded post to study defects of fatty oxidation in human skeletal muscle found in some metabolic diseases. Experience in enzymology or mitochondrial biology would be an advantage.

The appointment is available for three years, from 1st September 1985. Commencing salary up to £9,390 per annum on the Range 1A salary scale, according to age, qualifications and experience.

Candidates with a PhD or expecting to have gained a PhD by the Autumn should send an application with curriculum vitae with names and addresses of three referees to Dr D M Turnbull, Muscular Dystrophy Research Laboratories, Newcastle General Hospital, Westgate Road, Newcastle upon Tyne, NE4 6BE by not later than 31st August 1985. Further information may be obtained from Dr D M Turnbull or Dr H S A Sherratt (Telephone number (0632) 328511 Extension 3031).

Inorganic Chemist

£9,000 - £14,000

Amersham, Bucks

Amersham International plc is a highly successful and expanding UK Company, and a world leader in the supply of radiopharmaceutical products used in vital clinical diagnostics by hospital laboratories throughout the world.

Continued expansion of our R&D effort in radiopharmaceuticals has provided an excellent opportunity for a first class Inorganic Chemist to join a highly professional team pioneering new areas of interest for future product developments.

The post will ideally suit a graduate or postgraduate Inorganic Chemist, probably in their mid 20's, capable of demonstrating initiative, self-motivation and the flexibility to solve problems outside their specialist field. An interest in the synthesis and characterisation of novel transition metal compounds would be particularly relevant.

Salary to reflect ability will be within the range of £9,000 - £14,000 and is supported by an excellent benefits package including relocation assistance, where appropriate, to this pleasant South Bucks location.

Please write with full details to David Riley at the address below. Alternatively telephone Little Chalfont (02404)4488, ext. 3577 for an application form.

The Queen's University of Belfast LECTURESHIPS

Department of Pure and Applied Chemistry

Applications are invited for two lectureships in Inorganic Chemistry, tenable from 1st October, 1985 or such other date as may be arranged. One of the lectureships is a 'New Blood' post for which candidates should preferably be under the age of 35 and not already hold a permanent University appointment in the United Kingdom. The successful candidates will probably have previous research experience in one of the following areas: main group chemistry, organometallic chemistry, bio-inorganic chemistry, inorganic solid state chemistry, although well qualified candidates with other fields of interest are encouraged to apply.

Salary range: £7,521 - £14,925 per annum with contributory pension rights under USS, initial placing depending on age and experience. One of the appointments will be made within the first four points on the scale. £7,521, £7,980, £8,451, £8,922 and will be subject to a period of probation of up to three years.

Further particulars may be obtained from the Personnel Officer, The Queen's University of Belfast, Northern Ireland, BT7 1NN. Closing date: 23rd September 1985

(7206)A

UNIVERSITY OF EDINBURGH Human Genetics Unit POST-DOCTORAL/ GRADUATE RESEARCH ASSOCIATE

A post-doctoral or graduate research associate is needed to establish, organise and manage a prototype DNA service laboratory for the East of Scotland. The objective will be to obtain newly developed DNA probes from other laboratories and to demonstrate their usefulness in prenatal diagnosis and carrier detection of human genetic diseases. Since the Human Genetics Unit is associated with the MRC Clinical and Population Cytogenetics Unit, there will be opportunity for original research in association with the latter Unit's molecular biology group.

Applicants should have organisational skills, a commitment to clinically useful work and the ability to communicate with the medical profession. Experience in standard DNA techniques is essential, as is knowledge of the use of linkage in diagnosis of genetic disorders

The post is funded by a grant from the Scottish Home and Health Department, running to April 1988 in the first instance.

Salary within the range £7,520 to £8,920 (1A) or £6,600 to £8,920 (1B) depending on age and experience.

Please apply to Dr D J H Brock, Human Genetics Unit, Western General Hospital, Edinburgh, EH4 2XU, enclosing a curriculum vitae and the names of two referees. Informal enquiries may be made to Dr Brock (Tel 031 332 7917).

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF GEOLOGY TECHNICIAN GRADE 3

in the recently established Sedimentology Laboratory. The successful applicant will be responsible for operating a range of sedimentological research techniques, assisting in training students in these techniques and maintaining the laboratory. Experience of grain-size analysis, heavy mineral separation, cathodoluminescence microscopy, impregnation and staining techniques as applied to sediments and sedimentary rocks is required.

Candidates must possess HNC or equivalent as a minimum qualification but applications from graduates in Earth Sciences will also be welcomed. A minimum of eight years experience is also required.

Salary within the range £6,581 — £7,684 per annum (under review).

Application forms may be obtained from the Registrar, the University, PO Box 147, Liverpool, L69 3BX.

Quote Ref: PER/173/N

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY POSTDOCTORAL POSITION IN MOLECULAR PARASITOLOGY Department of Pure and Applied Biology POSTDOCTORAL SCIENTIST

required for a new development the immunology and molecular biology of filarial nematode parasites man. This position will involve combination of monoclonal antibodies and recombinant DNA technologies in the immunodiagnosis human filariasis, a major tropical disease. The successful applicant will join an existing research group at South Kensington site where the techniques are established. With familiarity with one of these fields would be advantageous, no previous experience of working with parasites would be necessary.

The project has been funded two years, renewable for a third, and the position is available immediately although appointment may be delayed for a suitable applicant. Salary will be on scale 1A, current £8,753 - £13,380 (under review) including London Allowance. Applicants should submit their cv and names of two referees by 6 September 1985 to Dr R M Maizels, Dept Pure and Applied Biology, Imperial College, London SW7 2BB, from whom further particulars may be obtained on 01-589-5111 ext 7485. (7349)A

UNIVERSITY OF MALAYA PETROLEUM GEOLOGIST

Applications are invited for a visit appointment of approximately year, beginning mid 1986. The appointment may be extended or renewed by mutual agreement.

Experience in petroleum industry is essential. Applications are especially invited from academicians who may be on sabbatical leave or who have retired from the industry. Salary will depend on the qualifications and experience of the candidate and will be within the range US\$15,000 to US\$30,000 annum. Air passage and accommodation will be provided.

The appointee will be responsible for planning and conducting undergraduate instruction in Petroleum Geology and related courses, and developing research co-operate with the petroleum industry.

Applications forms can be obtained from the Deputy Registrar (Establishment), University of Malaya, Kuala Lumpur 22-Malaysia. Applications should reach the Deputy Registrar before November 15, 1985. The Head, Department of Geology, University of Malaya, can be contacted for further

**THE NATURE
CONSERVANCY COUNCIL
HIGHER SCIENTIFIC
OFFICER**

2 year contract Higher Scientific Officer to work as an assistant on the National Countryside Monitoring Scheme

The National Countryside Monitoring Scheme (NCMS) aims to monitor habitat change throughout the British Isles using photogrammetric and computer based systems. The assistant will be part of a small team working on the NCMS project and his/her primary task will be the running of the digital mapping system which has been specifically designed for this project

The post will initially be based in Edinburgh, however, it is anticipated that the assistant will move with the project to the Peterborough office at a later date.

Qualifications and experience. Applicants should have a degree in a relevant subject and at least 2 years postgraduate experience. A good knowledge of computing and in particular digital mapping systems is required as is experience with aerial photographs. Some ecological background would be useful.

Salary depending on qualifications and experience: £7,788 rising to £10,541.

For an application form and further details of the post, please contact Miss B A Meredith, Personnel I, Nature Conservancy Council, Northminster House, Peterborough, PE1 1UA, to whom completed forms should be returned by 31 August 1985.

The Nature Conservancy Council is an equal opportunity employer. (7335)A

**MEDICAL RESEARCH
LABORATORIES,
THE GAMBIA
RESEARCH OFFICER IN
IMMUNOLOGY**

Applications are invited for a post of research officer in immunology at the MRC Laboratories in The Gambia. The successful candidate will be involved in studies in the immunology of human malaria and, in particular, in the development of human monoclonal antibodies to malaria antigens. He or she will work in close collaboration with scientists in laboratories in the UK. The successful candidate must have extensive previous experience in the characterisation and separation of antigens and antibodies; previous experience in parasitology is not essential. An initial contract of 2 years will be offered which may be renewed. Salary will be determined by qualifications and experience

Applications should be submitted to Miss K M Johns, MRC Head Office, 20 Park Crescent, London W1N 4AL from whom further details can be obtained. The closing date for applications is 30 August

**THE UNIVERSITY OF
MELBOURNE
RESEARCH FELLOW
GRADE 2
(EXTENDIBLE TENURE) IN
IMMUNOPARASITOLOGY**

in the
Department of Veterinary
Preclinical Sciences

Applications are invited from Immunologists/Immunoparasitologists interested in cellular immunity to cestode and trematode infections of sheep.

The research project is a collaborative study between the Sheep Biology Unit within the Department of Veterinary Preclinical Sciences and the Immunoparasitology Unit, Department of Veterinary Paraclinical Sciences. The Units are committed to ongoing projects on lymphocyte antigens, immunity to cestodes, cestode vaccines and lymphocyte recirculation using hybridoma and recombinant DNA techniques

The position is funded by the Wool Research Trust Fund and is available to 30th June 1986. The grant, however, has been awarded for a period of two years, with the possibility of further renewal. Commencement salary will be towards the base of the Research Fellow Grade 2 scale of \$A26,236 - \$34,467 per annum.

Further printed information regarding details of application procedure and conditions of appointment is available from the Appointments Officer (Academic), University of Melbourne, Parkville, Victoria 3052, Australia, or the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF

Applications, in duplicate, including names and addresses of at least three referees and quoting position number 260 A577, should be addressed to the Staff Officer, University of Melbourne, and close on 31 August 1985.

Equal opportunity in employment is the policy of the University of Melbourne. Selection is based on merit and all applications will be assessed regardless of sex, race, ethnicity or disability.

Applications from both men and women are invited for all vacancies. (W2102)A

**POSTDOCTORAL/
RESEARCH**

Associate position available to study RNA Processing in animal cells and viruses. Background either in Biochemistry, Microbiology or Molecular biology needed. Experience in recombinant DNA technology desirable. Salary negotiable.

Send resume with two names for references to Dr Mary Edmonds, Department of Biological Sciences, University of Pittsburgh, Pittsburgh, PA 15260.

Equal Opportunity / Affirmative Action Employer

**CSIRO
AUSTRALIA
SENIOR PRINCIPAL RESEARCH SCIENTIST
\$A47,501 — \$A52,212
DIVISION OF ENTOMOLOGY
CANBERRA AUSTRALIA**

GENERAL: The Division carries out basic and applied biological research on insects and related arthropods so as to acquire knowledge relevant to the solution of problems of economic and social significance. The research involves the study of the identity, abundance, and distribution of insects; and of their behaviour, pathology and genetics. The Division is a major centre in Australia for such research and has a professional staff of 120.

The Division's research activities are grouped into a number of sections, each headed by a senior scientist whose role includes providing scientific leadership, control of resources and advice to the Chief of the Division on the research direction of the section, as well as actively initiating and maintaining personal research projects.

The Division has recently established a molecular biology program to investigate the relevance of recombinant DNA to basic and applied entomology. Current projects include studies on eukaryote chromosome organisation and behaviour, gene structure and function, gene transfer technology, the molecular basis of insect development, and molecular analysis of entomophilic nematodes and their bacteria. The Division is also interested in commencing research on the molecular analysis of insect behaviour and communication.

DUTIES: A vacancy exists for a senior scientist to provide research leadership to the molecular biology, physiology, biochemistry and physical sciences programs. The appointee will be familiar with modern techniques of molecular biology and will be expected to develop a personal research program in molecular biology, physiology or biochemistry of insects.

QUALIFICATIONS: A PhD degree or equivalent qualifications in an appropriate field. An excellent record of contribution to research knowledge in this field is required, together with the capacity for research leadership of a high order.

TENURE: Indefinite with Australian Government superannuation benefits available.

SALARY RANGE: Senior Principal Research Scientist, but for exceptionally eminent candidates, consideration may be given to appointment at a higher level.

APPLICATIONS: Stating relevant personal particulars, including details of qualifications and experience, the names of at least two professional referees and quoting reference No A2107, should be directed to:

The Chief

New York Medical College,
Valhalla, NY 10595.**

(NW116)A

UNIVERSITY OF BRISTOL DEPARTMENT OF BIOCHEMISTRY AND UNIT OF MOLECULAR GENETICS COORDINATED PROGRAMME IN PROTEIN ENGINEERING

The SERC Biotechnology Directorate and several industrial sponsors have recently established an initiative to stimulate research in protein engineering. Bristol, is one of a small number of centres chosen for this coordinated programme.

Applications are invited for a MOLECULAR BIOLOGIST

of post-doctoral (Research Assistant 1A) status, preferably with some cloning and/or M13 sequencing experience.

Initially, the project will involve the cloning and sequence determination of phosphoglycerate kinase (PGK) genes isolated from thermophilic bacteria. Comparison of these sequences with the known sequence of yeast PGK will then form the basis of a multidisciplinary project (involving protein engineering, protein structure determination, computer graphics, etc.) aimed at establishing and exploiting the factors affecting protein thermal stability.

The position, which is available immediately, is initially tenable for three years with a starting salary in the range £7,520 — £8,920 p.a. according to age and experience.

Applications, including curriculum vitae and the names of two referees, should be sent as soon as possible to Dr L Hall at the Department of Biochemistry, University of Bristol, Medical School, Bristol, UK. (7312)A

THE UNIVERSITY OF SHEFFIELD DEPARTMENT OF PHYSICS SPACE PLASMA PHYSICS RESEARCH

We wish to recruit research staff at a postdoctoral level within the Space Physics Group, to be responsible for the scientific direction of investigations into plasma processes in the earth's magnetosphere and the solar wind.

One post is to study plasma motions and structures in the inner magnetosphere, both by observing natural VLF radio waves and by measuring Doppler shifts of a whistler mode signal from a northern hemisphere VLF transmitter, at Faraday station, Antarctica. A special receiver is currently under construction and will be deployed in early 1986.

The other post is concerned with the utilisation of data from the AMPTE satellites, to study wave-particle interactions in the outer magnetosphere and the solar wind. This will involve the data from the UKS wave experiment and other instruments on the UKS and IRM spacecraft.

Both posts will involve working with existing small teams and are available immediately for about two years in the first instance. Salary is on the RAI scale (£7,520 — £11,675, under review) according to age and experience. Letter of application and curriculum vitae should be sent to Professor G Turner FRS, Head of Department, Department of Physics, Sheffield S3 7RH (from whom further particulars are available) by 30 August 1985. Please (7312)A

TAYSIDE HEALTH BOARD DUNDEE GENERAL HOSPITALS NINEWELLS HOSPITAL & MEDICAL SCHOOL MOLECULAR BIOLOGIST

A Postdoctoral Scientist is required for a newly established Molecular Genetics Laboratory which will apply recombinant DNA techniques to the diagnosis of human disease. The post is funded initially for 3 years and work will be undertaken in the cytogenetics section of the University Department of Pathology and will be supported by adequate technical and laboratory facilities. The Laboratory is a participating member of a National Molecular Genetics Consortium aiming to provide a comprehensive service for Scotland. Applications should be experienced in the application of recombinant DNA methods. The appointment will be graded as Senior Cytogeneticist, the salary is £9,415 - £12,173.

Application forms and job descriptions from the Personnel Department, Ninewells Hospital. Tel: Dundee 60111, Ext 2578, quoting Reference Number GH/25/85. Closing date for completed applications is 20th August, 1985 (7352)A

SOUTH BIRMINGHAM HEALTH AUTHORITY

Birmingham Accident Hospital

Applications are invited for the position of

RESEARCH ASSISTANT

whole-time (Basic Grade Biochemist) to work in the Skin Culture Laboratory, Birmingham Accident Hospital. 1 Year contract in the first instance, commencing September 1985. Salary £6,559

Please send CV for further details and job description to Unit Administrator, Birmingham Accident Hospital, Birmingham. B15 1NA. (7355)A

ST MARY'S HOSPITAL MEDICAL SCHOOL (University of London)

Norfolk Place, London W2 1PG RESEARCH TECHNICIAN

required for the Department of Clinical Pharmacology for a period of two years. The research, which is funded by the British Heart Foundation, will primarily involve studies on the pulmonary responses to hypoxia and the effects of drug treatment.

Candidates with a training in biochemical pharmacology are encouraged to apply. Experience in adrenergic pharmacology and/or receptor binding techniques may be preferred.

Starting salary £5,035 plus £1,084 p.a. London Allowance.

Applications in the form of a cv and names of two referees should be sent to Assistant Secretary (Personnel) at the above address no later

YORK UNIVERSITY DEPARTMENT OF EARTH AND ATMOSPHERIC SCIENCE

DYNAMIC METEOROLOGIST

The Department of Earth and Atmospheric Science at York University invites applicants for positions of University Research Fellow in the area of dynamic meteorology. The Fellowships are research positions funded by the Natural Sciences and Engineering Research Council (NSERC) at the level of Assistant Professor tenable for up to five years. It is expected that the successful candidates will be prime candidates for tenure stream appointments in the department as they become available in the next few years.

Further information can be obtained by contacting Prof. John C. McConnell, Chairman, Department of Earth & Atmospheric Science, York University, 4700 Keele Street, Downsview, Ontario M3J 1P3.

These positions are tenable only by citizens or permanent residents of Canada at the time of application. In order to meet the NSERC deadline of 1st November, for fellowships to be awarded in 1986, York will require formal application by 30th September 1985. (NW49)A

Applications are invited for a POSTDOCTORAL RESEARCH ASSISTANT

interested in joining a group working on gene regulation in African Trypanosomes. The candidate should have experience in the techniques of molecular genetics. Salary according to BAT III/IIa (DM 42,700, — DM 46,600, — pa).

Prof Dr P Overath, Max-Planck-Institut für Biologie, Corrensstrasse 38, 74 Tübingen, West Germany. (W2089)A

UNIVERSITY OF ST ANDREWS

DEPARTMENT OF BIOCHEMISTRY AND MICROBIOLOGY

Applications are invited from medical or science graduates for a Demonstratorship in the Department of Biochemistry and Microbiology. The Demonstrator will assist in the teaching of medical and science classes and opportunities for advanced study will be available.

Salary £8,450 per annum, plus superannuation. The appointment is for the period 1st October 1985 to 31st May 1986. The appointment may be renewable for the corresponding period in the following academic year.

Further particulars may be obtained from the Secretary, Department of Biochemistry and Microbiology. Applications (two copies preferably in typescript) with the names of two referees should be submitted, before 25 August 1985, to the Establishments Office, University of St Andrews, College Gate, St Andrews, Fife, KY16 9AJ. (7312)A

UNIVERSITY OF LONDON

The Cardiothoracic Institute
New Blood Appointment
in the Department
of Thoracic Medicine

Applications are invited from candidates intending to pursue a career in Academic Medicine or Research for a 'New Blood' appointment in the Department of Thoracic Medicine. The successful candidate is likely to be a clinical or non-clinical scientist with some experience in immunological, cell biological or microbiological research methods. He or she will be expected to contribute new ideas in this area of research and to carry them through experimentally within the current programme of research into cellular, biochemical and host defence aspects of pulmonary disease currently conducted in the Department of Medicine. It is anticipated that appropriate Honorary Status would be granted to a clinical appointee by Brompton Hospital.

Candidates should not hold a permanent University appointment in the UK nor exceed the age of 35 (non-clinical) nor 38 (clinical) years. Appointment will be on the Lecturer or Senior Lecturer Scale. A London Allowance is payable.

Applicants should apply by letter, enclosing 8 copies of their curriculum vitae, a statement of not more than 500 words on why they are applying for the post and the names and addresses of 3 referees to: The Secretary, Cardiothoracic Institute, Fulham Road, London SW3 6HP from whom further particulars can be obtained.

Closing date for applications: 13 September 1985.

(7334)A

UNIVERSITY OF OXFORD

DEPARTMENT OF
HUMAN ANATOMY

GRADUATE RESEARCH
ASSISTANT (Grade 1B)

A position is available in the department to work with Dr CD Stern on a project funded by the Medical Research Council, to study the roles played by cell lineage and by cell interactions in segmentation in vertebrate embryos. Applicants should have obtained, or should expect to obtain, a First Class or Upper Second Class Honours degree in Biology, Zoology, Pre-clinical Medicine or related subjects. The position will be available in October 1985 or as soon as possible thereafter, it will be tenable for three years and the salary will be according to the 1B scale: £6,600 — £7,520 per annum plus a conference allowance. The successful applicant may have the opportunity to register for a higher degree.

Applications in writing, including curriculum vitae and the names and addresses of two referees should be sent to: Dr CD Stern, Department of Human Anatomy, South Parks Road, Oxford OX1 3PS.

THE ROWETT
RESEARCH INSTITUTE

Bucksburn, Aberdeen,
AB2 9SB

2 Year Post-Doctoral
Appointment Funded by
Scottish Home & Health
Department
Biochemist/ Physiologist/
Pharmacologist
HSO/SSO Grade

A well qualified research scientist with a knowledge of lipid metabolism, arachidonic acid metabolism and cardiovascular physiology/ pharmacology is required to work under the supervision of Dr K W J Wahle in the Biochemistry Division.

The project relates to the effect of isomeric monoenoic fatty acids on PUFA metabolism and eicosanoid synthesis in cardiovascular tissues/ membranes.

Qualifications: First or upper second class honours degree and a PhD in a relevant subject. At least 4 years post-graduate experience is required for SSO grading.

Salary Scales: HSO £7,788 to £10,541 pa, SSO £9,772 to £12,653 pa with placing according to experience.

The position is Superannuable and the Institute is an Equal Opportunities Employer.

Applications in writing together with full CV and the names/addresses of 2 referees should be sent to the Secretary of the Institute from whom further particulars are available. Tel No 0224-712751 Ext 338.

Closing date: 29th August 1985.
(7327)A

UNIVERSITY OF
EDINBURGH

DEPARTMENT OF RESPIRATORY
MEDICINE

Applications are invited for the post of

RESEARCH ASSOCIATE

funded for 3 years by the Wellcome Trust to work on aspects of the control of breathing by hypoxia in conscious humans including 1) physiological mechanisms of the potentiation by exercise, 2) changes with age, and 3) the role of the response in the development of chronic bronchitis and emphysema. Applicants should hold a good Honours degree in a physiological science with at least 3 years relevant postgraduate experience and be under the age of 32 years. Appointment will be on the 1B scale (£7,980 pa).

Further information may be obtained from Professor D C Flenley, Department of Respiratory Medicine, City Hospital, Greenbank Drive, Edinburgh EH10 5SB to whom applications including names and addresses of two referees should be sent by 19th August.

CSIRO

AUSTRALIA

RESEARCH FELLOW

\$A26,001 — \$A32,083

DIVISION OF APPLIED
ORGANIC CHEMISTRY
FISHERMAN'S BEND VIC

GENERAL: The Division has a staff of approximately 100, including about 50 professional scientists. Investigations are carried out in programs of biological organic chemistry, industrial chemistry and polymer science. The Biosynthetic Chemistry group is part of the Biological Organic Chemistry Program, which carries out work in the synthesis of biologically active compounds for development and manufacture in Australia for the world market.

DUTIES: As a member of the Biosynthetic Chemistry group the appointee will collaborate in research on the synthesis and development of agrochemicals and pharmaceutical agents. The research involves multidisciplinary work in synthetic chemistry in several fields of biology, physical chemistry and computer design of the compounds.

QUALIFICATIONS: A PhD degree or equivalent qualifications in the field of organic synthetic methods and the operation and interpretation of data obtained using organic chemistry instrumentation e.g. NMR, IR, Mass Spectrometry, GLC, HPLC. Experience in the synthesis of biologically active compounds would be an advantage.

TENURE: A term of three years with Australian Government superannuation benefits available.

APPLICATIONS: Stating relevant personal particulars, including details of qualifications and experience, the names of at least two professional referees and quoting reference No A1051, should be directed to:

CSIRO IS AN EQUAL OPPORTUNITY EMPLOYER (W2112)A

UNIVERSITY OF EDINBURGH

DEPARTMENT OF VETERINARY PATHOLOGY

WELLCOME TRUST LECTURESHIP IN MOLECULAR BIOLOGY

Applications are invited for a Wellcome Trust Lectureship in Molecular Biology in the Department of Veterinary Pathology, University of Edinburgh. The Department has a major interest and excellent facilities for basic research in immunology and the molecular aspects of pathology. The person appointed will join an active research group working on the immunology of persistent viral infection and will be expected to work on the molecular biology of pestiviruses (Border Disease virus of sheep, virus of Bovine Viral Diarrhoea — Mucosal Diseases of cattle) and investigate the molecular biology of the interactions between these viruses and the cells of immune systems in sheep. Molecular biology techniques have been introduced to the Department, and the successful applicant will be expected to further develop Molecular Biology in relation to the Department's research interests in immunology and its teaching programmes. Applicants must have research experience and a training in recombinant DNA technology and an interest in immunology.

The salary will be on the lecturers' scale (£7,190—£14,125). Starting salary depending on age, qualification and experience. The Lectureship is for three years in the first instance with renewal for a further two years on satisfactory review. Candidates should not be older than 35 years of age. Further particulars can be obtained from Professor I. McConnell, Department of Veterinary Pathology, University of Edinburgh, Summerhall, Edinburgh EH9 1QH (Tel: 031 667 1011 ext. 5322 or 5343). Candidates will be asked to submit a 500 word summary of the proposed research and should request the further particulars.

Applications (6 copies) giving the names of 3 referees should be sent to:

The Personnel Office, University of Edinburgh, 63 South Bridge, Edinburgh EH1 1LS.

Closing date for applications is 30th August, 1985, with appointment as soon as possible after that date. Applications from overseas should lodge their interest by this date with applications to follow.

Please quote reference No 5266.

(7190)A

ASSISTANT PROFESSOR

Department of Pathology is seeking a Hematopathologist for a Junior Faculty tenure accruing position. Candidate must have a M.D. degree and must have experience in diagnostic hematopathology. A strong interest in pursuing research activities in the areas of tumor biology, cellular immunology or molecular biology. It is expected that such an individual would share diagnostic responsibilities including interpretation of bone marrow and lymphoid tissue biopsies and immunophenotyping of normal and neoplastic leukocytes using modern flow cytometric techniques and tissue section labelling. The individual will also be involved in the training of pathology residents and graduate students. Recruiting deadline is October 1, 1985 with an anticipated start date of November 1, 1985.

Applications should be sent to: Paul C. Braylan, M.D. Professor, Department of Pathology, Box J-275, College of Medicine, University of Florida, Gainesville, Florida, 32610.

Equal Opportunity Employment/Affirmative Action Employer.

BAKER MEDICAL RESEARCH INSTITUTE Melbourne, Australia PROTEIN BIOCHEMIST

Applications are invited for a Senior Research Officer in the Lipoprotein Biochemistry Laboratory at the Institute. The position requires a person with Postdoctoral experience in protein chemistry, preferably related to lipoproteins although this is not essential. Our research explores biochemical relationships between lipoprotein metabolism and atherosclerosis, requiring protein isolation, use of immunochemical techniques, cell biology, etc.

Candidates should submit a curriculum vitae containing research experience, publications and names, addresses and telephone numbers of three referees to Dr N Fidge, Baker Medical Research Institute, Commercial Road, Prahran, Victoria, Australia 3181.

(W2006)A

UNIVERSITY OF BRISTOL

POSTDOCTORAL
RESEARCH ASSOCIATE

STABILITY OF
NON-AQUEOUS
DISPERSIONS

Investigations into the role of electrostatic interactions in controlling the stability/flocculation behaviour of colloidal dispersions in non-aqueous media require the accurate measurement of surface charge. To this end, it is intended to develop either a laser-Doppler electrophoretic technique for use with non-aqueous dispersions.

The project will be for two years starting on or after October 1st 1985, and will be carried out in the Physical Chemistry Department at Bristol University with Dr B. Vincent. The starting salary will be at a suitable point on the University IA scale range of £7,520 to £12,150, depending on age and experience.

Applicants, with a suitable background in physical chemistry or physics, should write to Dr B. Vincent, Dept. of Physical Chemistry, University of Bristol, Bristol BS8 1TS, as soon as possible. A curriculum vitae, together with the names and addresses of two referees, should be included. (7319)A

UNIVERSITY OF
LEICESTER

DEPARTMENT OF
MICROBIOLOGY

POST DOCTORAL
RESEARCH ASSOCIATE
RESEARCH TECHNICIAN
(Grade III)

Molecular Biology of Bacterial
Virulence

Applications are invited for these two positions funded by the Medical Research Council, and tenable for up to three years from 1st October 1985. Salary according to age, experience and qualifications.

The work will involve the detailed molecular analysis of surface structures of *Escherichia coli* involved in mediating adhesion to human cells. This is a collaborative project with Prof K Jann, Max Planck Institute for Immunobiology, Freiburg, West Germany and will involve exploitation of monoclonal antibodies and techniques of gene cloning and analysis. Experience in recombinant DNA, immunology and/or protein biochemistry would therefore be an advantage.

Applications, in the form of a curriculum vitae with the names of two referees, should be sent to Dr G J Boulnois, Department of Microbiology, Medical Sciences, University of Leicester, University Road, Leicester, LE1 7RH, UK (Tel 0533-51234, Ext 262). (7341)A

UNIVERSITY OF
CAMBRIDGE

DEPARTMENT OF PARASITOLOGY
UNIVERSITY LECTURER

Applications are invited for a post of University Lecturer in the Department of Parasitology, appointment to commence on 1 January 1986 or as soon thereafter as possible. (In 1987 the Department of Parasitology will unite with the Department of Pathology to form a single department.)

Candidates should hold a PhD degree or equivalent and have several years post doctoral experience in parasitology and in the application of molecular, biochemical or immunological techniques to the investigation of the developmental biology of parasites and of host/parasite relationships. The successful candidate will be expected to teach natural science, medical and veterinary students at undergraduate and postgraduate levels.

Stipend: £9,875 by eleven annual increments of £15,085 (under review).

Further information about the duties and conditions of appointment may be obtained from the Secretary of the Appointments Committee for the Faculty of Biology 'A', 19 Trumpington Street, Cambridge, CB2 1QA, to whom applications (10 copies) including curriculum vitae, list of publications and the names of not more than three referees, should be sent so as to reach him not later than 1 October 1985. (7314)A

LECTURER IN
PHYSIOLOGY

University of Cape Town/
Cape Provincial Administration

Applications are invited for the above post for appointment as soon as possible. Preference will be given to applicants with interests in neurophysiology, renal physiology or mineral metabolism.

The post is full-time and under the terms of the joint agreement between the University and the Cape Provincial Administration.

Salary range R20 482 - R34 070 per annum with an annual bonus and attractive staff benefits.

Applicants should submit a full curriculum vitae stating qualifications, teaching and research experience, interests and publications, present salary and the names and addresses of three referees not later than 9 September 1985 to the Registrar, (Attention: Appointments Office Ref: AC/5714) University of Cape Town, Private Bag, Rondebosch, 7700, South Africa. Further information may be obtained from the Registrar or The Secretary, SA University Office, Chichester House, 278, High Holborn, London WC1V 7HE.

The University's policy is not to discriminate on the grounds of sex, race or religion. Further information on the implementation of this policy is obtainable on request. (W2092)A

M.R.C. CLINICAL RESEARCH CENTRE
(NORTHWICK PARK HOSPITAL)
WATFORD ROAD, HARROW
MIDDLESEX HA1 3UJ

NON-CLINICAL SCIENTIST

Applications are invited from post-doctoral microbiologists for a 3-year short-term appointment to study the host-parasite relationships between mammalian cells and bacteria, viruses and mycoplasmas. The research programme will be concerned with identification of glycoprotein or glycolipid receptors for infective agents on the host-cell membranes.

The successful candidate will join the Applied Immunochemistry Research Group headed by Dr Ten Feizi from whom further information can be obtained (Tel 01-864 5311 ext 2352).

Salary will be within the range £10,153 — £16,158 (inclusive of London Weighting) depending on experience. Application forms are obtainable from Miss B A Shaw, Personnel Section, quoting reference 108/1/3905.

Closing date for applications 15th August 1985

(7311)A

UNIVERSITY OF
NOTTINGHAM

Department of Zoology

POSTDOCTORAL
RESEARCH ASSISTANT

A one-year post is available from 1st October 1985 to work on a SERC funded project looking into risk-sensitive and time-constrained foraging in shrews. Applicants should have a working knowledge of optimal foraging theory and experience with laboratory behavioural studies. The appointment will be within the first two points of the post-doctoral scale.

Applications to be sent as soon as possible with curriculum vitae to Dr C J Barnard, Department of Zoology, University of Nottingham, University Park, Nottingham, NG7 2RD. (7332)A

UNIVERSITY OF
BIRMINGHAM

Faculty of Medicine and
Dentistry

DEPARTMENTS OF IMMUNOLOGY
AND PHYSIOLOGY
RESEARCH FELLOW/
ASSOCIATE

Applications invited for the above post to investigate the use of monoclonal antibodies to identify and characterise cardiac specific proteins.

Post available for up to two years funded BHF grant to Dr G K Dhoot and Professor S V Perry starting October 1985. Salary on scale £6,600 — £8,920 or £7,520 — £12,150 with superannuation.

Candidates should have research experience in protein chemistry and/or immunochemical techniques.

Further particulars Assistant Registrar, Medical School, University of Birmingham, B15 2TT, to whom applications (3 copies) should be sent by 3 September 1985. Quote Ref RA/IMP/GD. (7354)A

UNIVERSITY OF
CAMBRIDGE

DEPARTMENT OF BIOCHEMISTRY
MOLECULAR BIOLOGIST

to work on the control of germination of castor beans. The work involves the use of probes for the mRNA of purified enzymes from glyoxysomes construction of genomic clones, DNA sequencing and the application of plant growth factors. This is funded for 11 months from 1st October 1985.

Salary according to age and experience £7,520 — £9,860 (under review).

Applications should be sent as soon as possible to Professor D H Northcote, FRS, Department of Biochemistry, University of Cambridge, Tennis Court Road, Cambridge, CB2 1QW (7323)A

UNIVERSITY OF BRISTOL

DEPARTMENT OF
MICROBIOLOGY AND UNIT OF
MOLECULAR GENETICS

PREDOCTORAL
RESEARCH ASSISTANT

Applications are invited, as soon as possible, for the above post, which is supported by the Medical Research Council for 3 years. The work will examine structure-function relationships in *E coli* membrane proteins concerned with tetracycline transport and efflux. Applicants should have an honours degree in a biological science preferably with some training in molecular genetics, bacterial resistance plasmids or bacterial cell membranes.

The starting salary will be £6,600 rising to £7,520 per annum in the third year (Research Range 1B; salaries under review), and the successful candidate may be able to register for a higher degree. Further details can be obtained from Dr Ian Chopra, Department of Microbiology, The Medical School, University Walk, Bristol, BS8 1TD, to whom applications, including curriculum vitae and the names of two referees should be sent. (7337)A

Have you got the right chemistry?

Protein chemists experienced in the purification and physico-chemical analysis of proteins and antigens.

Recombinant DNA scientists experienced in cloning DNA fragments into plasmid vectors and nucleic acid isolation from mammalian genes.

Immunologists experienced in the development of enzyme-antibody conjugates and investigation into new immunoassay techniques.

Molecular geneticists experienced in gene identification, design of synthetic oligonucleotide probes and hybridisation techniques.

Cell biologists experienced in cell physiology, tissue culture and hybridoma - monoclonal antibody technology.

ICI is currently going through a period of major diversification and expansion into the medical diagnostics field with the establishment of the new ICI Diagnostics Group. Backed by substantial scientific and financial resources, the new group is pursuing a broad strategy embracing in-house research, product licensing and collaborative projects designed to make the company a major force in diagnostics.

Shown here is the range of scientific personnel we seek to join a new and dynamic research team involved in the development of nucleic acid - and immunoassay - based diagnostics for medical applications. Emphasis will be strongly based on the design of new diagnostics and the use of non-isotopic detection technology.

We are interested in applicants holding a good first degree or suitable equivalent qualifications, and those holding a Ph.D with, preferably, postdoctoral experience. Candidates should have a broad interest in the diagnostics field together with a flexible and adaptable approach to research areas geared to the market place. This will require a rare combination of both research and practical interest in the development of non-isotopic nucleic acid and immunoassay systems.

In return, we offer excellent technical facilities in attractive 'Greenfield' surroundings, opportunities for rapid career progression as the group expands, highly competitive salaries and conditions and a generous relocation package.

We intend to hold a series of regional meetings during September when selected applicants will be invited to find out more about our move into medical diagnostics.

Those who wish to take advantage of this exciting opportunity should send details of their career to date to Dr Trevor Twose, R & D Manager.

KING'S COLLEGE LONDON

DEPARTMENT OF BIOPHYSICS
Applications are invited for a
POST-DOCTORAL RESEARCH ASSOCIATE

to work with Dr Roger Patient on the role of DNA supercoiling in establishing active chromatin structure and transcriptional activation, using tissue culture transfection and *Xenopus* oocyte injection

The post will be tenable for up to three years from January 1986. Salary in the range £7,520 - £12,150 pa plus £1,233 London weighting.

Further details may be obtained from Mr D M Drummie, MRC Cell Biophysics Unit, 26-29 Drury Lane, London WC2B 5RL, whom applications should reach by 29 August 1985, or by telephoning Dr Patient on 01 836 8851 (7312)A

KING'S COLLEGE LONDON (KQC)

University of London
Department of Biochemistry
POSTDOCTORAL RESEARCH ASSISTANT

A Postdoctoral Research Assistant is required to work with Dr J M Wrigglesworth on a SERC funded project to investigate the redox-linked Bohr properties of cytochrome c oxidase. The post will be available for two years from 1st October 1985 with a starting salary of £8,753 per annum inclusive.

Applications (with curriculum vitae and names and addresses of two referees) should be sent to Dr J M Wrigglesworth, Department of Biochemistry, King's College London (University of London), Campden Hill Road, Kensington, London W8 7AH.

Closing date: 30th August 1985. (7336)A

THE UNITED MEDICAL AND DENTAL SCHOOLS
Guy's Campus
POSTDOCTORAL RESEARCH ASSISTANT

required to join a team working on regeneration in the nervous system, with particular emphasis on the central nervous system. Applicants should have experience in neurohistological and immunocytochemical techniques; also electron microscopy and/or stereological techniques would be an advantage.

Further information from Dr S Standring, Department of Anatomy 01-407 7600 Ext 3349.

Applications, with full CV and names of two referees, to the Staffing Officer, Guy's Hospital Medical School, London SE1 9RT, quoting Ref: G/A/89, by 29 August 1985. (7366)A

UNIVERSITY OF OXFORD

DEPARTMENT OF AGRICULTURAL SCIENCE
RESEARCH ASSISTANT

Applications are invited from persons with a PhD or comparable research experience to develop a predictive model for the convective transport of solutes, especially nitrate, through soil. In addition to soil scientists, applied mathematicians, physicists and engineers interested in flow through porous media are invited to apply. The post, on Research Assistant scale 1A, will be funded by the AFRC for 3 years.

Applications, with curriculum vitae and the names of two referees, should be sent as soon as possible to Dr R E White, Department of Agricultural Science, Parks Road, Oxford, OX1 3PF, from whom further particulars can be obtained (7364)A

UNIVERSITY OF NEWCASTLE UPON TYNE
DEPARTMENT OF NEUROLOGY
POSTGRADUATE RESEARCH STUDENTSHIP

Applications are invited for a research studentship tenable in the Muscular Dystrophy Group Research Laboratories, Newcastle General Hospital. The successful applicant will read for the degree of PhD. Two topics are available: (i) investigation of genetic or acquired defects of the mitochondrial respiratory chain in human muscle disease using biomedical, cytochemical and immunological techniques; (ii) the use of cytochemical techniques to study the molecular differentiation of the muscle cell surface during development and regeneration of the neuromuscular junction.

Candidates should be appropriately qualified and possess at least a 2.1 Honours degree. Applications should be made as soon as possible in the form of a curriculum vitae, and candidates should include the names of two referees. The project for which the application is being made should also be identified. All correspondence should be sent to Professor J B Harris, Muscular Dystrophy Group Research Laboratories, Newcastle General Hospital, Westgate Road, Newcastle upon Tyne, NE4 6BE, from whom further information may be obtained. STUDENTSHIPS

UNIVERSITY OF NOTTINGHAM MEDICAL SCHOOL

DEPARTMENT OF PHYSIOLOGY AND PHARMACOLOGY
FRAME RESEARCH STUDENTSHIPS

Applications are invited for two AME-sponsored studentships for research into the metabolism and toxicity of xenobiotics in mammalian cultured cells. Each studentship will be tenable for up to three years from

October 1985, with a view to obtaining the degree of PhD. Candidates should hold a first or upper second class honours degree in Pharmacology, Biochemistry or a related subject. The terms and conditions of the studentships will be similar to those offered by the MRC/SERC.

Applications, including a curriculum vitae and the names of two referees, should be sent to Dr J Fry, Department of Physiology and Pharmacology, Medical School, Queen's Medical Centre, Nottingham NG7 2UH (telephone No 0602-700111 ext 97) from whom further information may be obtained. Applications should reach Dr Fry by the 31st August 1985. (7305)F

ROBERT GORDON'S INSTITUTE OF TECHNOLOGY

School of Nutritional Science

RESEARCH STUDENTSHIPS

Applications are invited from suitably qualified persons for Research Studentships in the above School.

Subject areas include: (a) Studies of the metabolic activity of human and bacterial populations. (b) Nutritional education. (c) Trace element metabolism. (d) Investigations of lipid metabolism.

Application forms from Personnel Department, Robert Gordon's Institute of Technology, Schoolhill, Aberdeen, AB9 1FR. (7330)F

THE MACAULAY INSTITUTE FOR SOIL RESEARCH

Department of Soil Organic Chemistry

RESEARCH STUDENTSHIP

Applications are invited for a 3-year Research Studentship, funded by the whisky industry, to study the involvement of copper in the whisky distillery process, the nature of copper complexes formed, their relation to whisky flavour and their removal from waste products. The holder of the studentship will be registered for degree of Doctor of Philosophy of the University of Aberdeen.

Further information may be obtained from The Secretary, The Macaulay Institute for Soil Research, Craigiebuckler, Aberdeen, AB9 2QJ, to whom applications giving the names and addresses of three referees should be sent by 26 August 1985.

FELLOWSHIPS

UNIVERSITY OF READING

DEPARTMENT OF MICROBIOLOGY

Post-Doctoral Research Fellow

Applications are invited for this fixed three year Fellowship supported by MRC to commence as soon as possible after 1 October 1985. The project is to study the functions of the genome of polio and other picornaviruses using site-directed mutagenesis of infectious, cloned cDNAs. The investigation forms part of a larger programme concerned with the development of new prophylactic and therapeutic agents against medically important picornaviruses. Previous experience of recombinant DNA techniques and/or of virology would be an advantage.

Starting salary up to £8,920 per annum (under review).

Candidates (PhD) should apply for application forms, quoting Ref. R34A to Personnel Officer, University of Reading, Whiteknights, P O Box 217, Reading RG6 2AH, telephone (0734) 875123 ext 233. Dr J W Almond, currently at the University of Leicester, is professor elect of the Department of Microbiology at the University of Reading. (7321)C

THE ROYAL SOCIETY GUEST RESEARCH FELLOWS

The Council of the Royal Society invites applications for the support of Guest Research Fellows. The object of this scheme, established in 1980, is to assist outstanding leaders in scientific research in the United Kingdom to invite as guests scientists of proven ability, normally resident overseas, to come and work with them for periods of between four months and one year. The aim is to provide for research needs which can best be met by such international collaboration, and proposed guests should be key workers, normally already holding established posts, who would bring unique expertise to their hosts in the United Kingdom. Emphasis in selection will be on the abilities and field of research of the applicant working in the United Kingdom and on those special contributions to the applicant's research which would be provided by the visitor and are not available in the United Kingdom.

Applicants must be working in departments of science (including agriculture, medicine, mathematics, engineering and technology) in universities or research institutions in the United Kingdom. Direct applications from intending guests from overseas are not acceptable.

Applications should be made on forms to be obtained from the Executive Secretary (GRF/ADH), The Royal Society, 6 Carlton House Terrace, London, SW1Y 5AG, and returned by 30 September 1985. (7304)E

UNIVERSITY OF MARBURG

MOLECULAR BIOLOGIST or PROTEIN CHEMIST

Applications are invited for POST-DOCTORAL

RESEARCH FELLOWSHIPS

funded for three to five years starting September 85 or January 86 (Salary according to BAT II/IIIa/b). The group focus on hormonal regulation of gene expression in vertebrates. Applicants should have experience in either molecular biology, microinjection or protein chemistry.

Applications including c.v. and the names of two referees should be sent to: Prof. M. Beato, Institut für Molekularbiologie, Emil-Mannkopff-Str. 1, D-3550 Marburg, West Germany. (W2100)E

POSTDOCTORAL FELLOWS (3)

Postdoctoral fellowships (3) are available to study the molecular basis of human disorders, in particular Cystic Fibrosis, Fanconi anemia and Multiple sclerosis. Individuals wishing to apply their training in molecular biology to problems of human genetic disease are especially encouraged to apply.

Salaries are in the range of \$20,000 (CAN) and appointments are for 2 to 3 years.

Send letters of application and curriculum to Dr M Buchwald, Department of Genetics or Dr J R Riordan, Department of Biochemistry, Hospital for Sick Children, 555 University Avenue, Toronto, Ontario, M5G 1X8 Canada. (NW114)E

UNIVERSITY OF LEICESTER

DEPARTMENT OF BIOCHEMISTRY POST-DOCTORAL FELLOW

Applications are invited for a CRC funded post-doctoral fellowship to work on the analysis of gene expression in rectal and breast carcinomas using in situ hybridization to mRNA in tissue sections. The work on rectal carcinoma will be concerned with the cellular localization and levels of mRNA's for the basement membrane proteins laminin and fibronectin.

The project on breast carcinoma will be concerned with the cellular localization of transcripts for a number of (onco) genes found to be differentially expressed in breast carcinoma. Whilst it is desirable that applicants have experience in recombinant DNA technology, it is by no means essential as the Department of Biochemistry has in depth expertise in this area of research. The position is for 2 years and is available immediately. Salaries within the range £7,520 to £12,150 depending upon age and experience.

Applications, including a curriculum vitae and the names of two referees, should be sent to Dr D R Critchley, Department of Biochemistry, University of Leicester, University Road, Leicester, LE1 7RH, from whom further details are available (0533 551234 x 387) (7340)E

WORKSHOPS

Deutsche Gesellschaft für Biophysik
**Workshop on
 Nucleocytoplasmic Transport**

September 26–28, 1985

Deutsches Krebsforschungszentrum, Heidelberg, F.R.G.
 Organized by R. Peters and M. Trendelenburg

Considerable progress has been made recently in nuclear targeting of oncoviral and karyophilic proteins, of steroid receptors and ribonucleoproteins, in the structure, biochemistry and assembly of the nuclear envelope, in transcript organisation, and in physical techniques for measuring molecular transport in single cells. By bringing together scientists of various disciplines the workshop will reassess the potential role of nucleocytoplasmic transport for gene expression, cell cycle and growth control. The workshop includes lectures, poster sessions and technical demonstrations. Sessions and chairpersons or speakers so far accepted:

Nuclear envelope

Blobel (New York), Gerace (Baltimore), Krohne (Heidelberg), Milligan (Heidelberg), Newport (San Diego)

Laser fluorescence microscopy

Axelrod (Michigan), Garland (Bedford), Peters (Frankfurt), Ware (Syracuse)

Video microscopy and cell biological techniques

Allen (Hanover), Edstrom (Heidelberg), Feldherr (Gainesville), Neuhaus (Ladenburg), Trendelenburg (Heidelberg)

Karyophilic proteins

Burglin (Basel), Franke (Heidelberg), Hall (San Francisco), Kleinschmidt (Heidelberg), Laskey (Cambridge)

Ribonucleoproteins

Brachet (Brussels), Daneholt (Stockholm), Mattaj (Basel), Scheer (Heidelberg)

Steroid receptors

Dierich (Strasbourg), Greene (Detroit), Schutz (Heidelberg)

Oncoviruses

Colman (Coventry), Gissman (Heidelberg), Graßmann (Berlin), A. E. Smith (Framingham)

Poster presentations: Submit an abstract of one page maximum

Registration fee: US \$75 or DM250 by check of money order

Deadline: August 15, 1985.

Address for registration, accommodation and poster abstracts:

Workshop secretariat, Mrs B. Schulz

Max-Planck-Institut für Biophysik

Heinrich-Hoffman-Str. 7, 6000 Frankfurt 71 (W2098)V

GRANTS & SCHOLARSHIPS

**THE UNITED MEDICAL
 AND DENTAL SCHOOLS**

St Thomas's Campus
 Department of Obstetrics
 Department of Pharmacology
 Two PhD Scholarships

One scholarship is in the field of neuroendocrinology; this project will involve studies of the control of the synthesis and release of hypothalamic releasing factors. The other scholarship concerns transcriptional

changes in diabetes; this project involves the characterisation of altered genomic products in liver and pancreas in diabetic animals and the effects of insulin and anti-diabetic drugs

Applications in the form of a curriculum vitae and the names and addresses of two referees should be sent no later than 14 September 1985 to the Secretary, Department of Pharmacology, St Thomas's Hospital Medical School, London SE1 7EH (7350)H

ASSISTANTSHIPS CONTINUED

**UNIVERSITY OF LONDON
 British Postgraduate Medical
 Federation**

The Cardiothoracic Institute

**RESEARCH
 ASSISTANTSHIP IN
 MEMBRANE BIOLOGY**

Applications are invited for a 3-year BHF supported research assistantship commencing in October, 1985. Candidates should possess a first or upper second class honours degree in an appropriate subject and will be expected to register for a PhD. The research project will involve the

study of the mechanism of ion conduction through cardiac membrane channels following their incorporation into planar phospholipid bilayers.

Salary on University of London Research Assistant scale IB. Post supernannuable under USS.

Further details are available from Dr A. Williams (01-486-3043).

Applications to include full curriculum vitae and names of three referees should reach the Secretary, Cardiothoracic Institute, Fulham Road, London SW3 6HP by 27 August 1985. (7361)P

CONFERENCES & COURSES

**FIRST INTERNATIONAL CONFERENCE
 OF ANTICANCER RESEARCH**

26–30 October 1985, Loutraki, Greece

Topics: Combination Chemotherapy, New Anticancer Agents: Development and Evaluation, Tumor Makers, Receptors, Monoclonal Antibodies in Diagnosis and Treatment of Cancer and Leukemia: Carcinogenesis (Mechanism, Environment, Nutrition) Invasion and Metastasis, Tumor Angiogenesis, Differentiation and Cancer Biology of Human Glioma Oncogenes, Leukemia and Lymphoma: Recent Advances, Strategies in the Development of New Tumor Markers, Chromosomes and Cancer, The Foundation of the International Institute of Anticancer Research.

Deadline for Late Registration and Submission of Abstracts: 10 September 1985.

Information: Dr John Delinassios, Anticancer Research, 5 Argypoulou Street, Kato Patissia, Athens GR-111 45, Greece. (W2106)C

**ANNOUNCING NATURE'S FIFTH
 INTERNATIONAL CONFERENCE**

October 7, 8, 9, 1985

START 1986 WITH A LOOK AT 1996

BIO/TECHNOLOGY'S PREMIER CONFERENCE

Whether you're an R&D Project Manager, VP of Research, a Senior Scientist, a Process Engineer, Department Chairman or an Academic Researcher—this is one conference you cannot afford to miss.

For your first conference, we've planned a series of free-wheeling discussions with researchers and research managers at the pace in biotechnology. You'll get up-to-the-minute developments in the world of molecular biology. You'll get a jump on the ideas and issues that will guide biotechnology in the '80s and '90s. Participation is limited. So don't delay. Register now to guarantee your place.

Location: Clarion Hotel, 1500 Canal St., New Orleans, LA 70112.

Reservations: Rooms can be booked directly with the hotel by calling 362-6000 or 1-504-522-4500. Be

certain to reserve early and mention your participation in the BIO/TECHNOLOGY CONFERENCE to take advantage of our special convention rates. **Singles:** \$53, \$60, \$68, \$75, \$80. **Doubles/Twins:** \$63, \$70, \$78, \$85, \$90.

Poster Sessions: Scientists are welcome to submit abstracts of work with commercial applications for consideration. Mail abstracts to Research Editor, BIO/TECHNOLOGY, 65 Bleecker Street, New York, NY 10012.

Exhibits: An exhibit of the latest in fermentation and separation equipment, instrumentation, and other products related to biotechnology will be on display.

To Register: Return the form with your check, credit card authorization or an authorized purchase order.

JANUARY 20, 21, 22, 1986

CLARION HOTEL NEW ORLEANS

CONFERENCE PROGRAM & SPEAKERS

JANUARY 20—MORNING

Molecular Biology of Plants and Animals: A View From the Frontier

Speakers:
David Flavell, President, Biogen Research

Goeddel, Director, Molecular Biology, Genentech
Jan Borlaug, CIMMYT, Mexico City and Director, Dept. of Soil and Crop Science, A&M

JANUARY 20—AFTERNOON

Seminar in Molecular Biology

David Goeddel, Co-Chairman
David Flavell, Co-Chairman
Colby, Director, Technology Development, Triton Biosciences

Seminar in Agricultural Biotechnology

Jan Borlaug, Chairman
Art Fraley, Manager of Plant Molecular Biology, Monsanto
Jim Evans, Vice President for Research, Plant Technology, Inc.
Les Arntzen, Associate Director of Central Research and Development, E.I. du Pont de Nemours and Co.

JANUARY 21—MORNING

Commercial Production Processes

Speakers:
John Lilly, Professor of Chemical Engineering, University College London
Art Herschberg, Department of Process Development, Genentech
Yukio Sugino, Director, Biotechnology Labs, Sankyo Chemical, Japan
Ephraim Katchalski-Katzir, Professor of Physics and Biotechnology, Tel Aviv University, Israel

JANUARY 21—AFTERNOON

Seminar in Scale Up

John Lilly, Co-Chairman
Art Herschberg, Co-Chairman
John Buckland, Director, Computerized Pilot Plant, Merck, Sharp, & Dohme

Stanley Tarnowski, Research Section Chief, Dept. of Bioseparations, Hoffmann-La Roche

Seminar in Fermentation

Yukio Sugino, Chairman
Arnold Demain, Director of Laboratory of Fermentation and Microbiology, MIT
Behzad Khosrovi, Senior Director, Process and Product Development, Cetus Corp.
William Tolbert, Research Fellow, Monsanto

Seminar in Immobilization & Biocatalysis

Ephraim Katchalski-Katzir, Chairman
Allen Laskin, Industrial Consultant, Chairman, BIO/TECHNOLOGY Scientific Board
Gary Calton, President, Purification Engineering, Inc.

JANUARY 22—MORNING

Innovations in Pharmaceuticals & Immunology

Speakers:
Bernard Moss, National Institutes of Health
Emil Thomas Kaiser, Haggerty Professor, Rockefeller University
George Poste, Vice President and Director of R&D, Smith Kline & French

JANUARY 22—AFTERNOON

Seminar in Vaccine Development

Bernard Moss, Chairman
Pablo Valenzuela, Vice President and Director of Research, Chiron Corp.
Mark Greene, Professor, Dept. of Pathology, Harvard Medical School

Seminar in Peptide Design

Emil Thomas Kaiser, Chairman
Gregory Winter, MRC, Mill Hill, Cambridge, U.K.
Gregory Petsko, Professor, Dept. of Chemistry, MIT

Seminar in Drug Delivery

George Poste, Chairman
Joseph Robinson, Professor of Pharmacy, Univ. of Wisconsin
Colin Gardner, Director of Analytical and Biological Research, Inter X, a subsidiary of Merck & Company

**SAVE \$50 WITH YOUR
EARLY REGISTRATION**

**Pay \$325.00 before Oct 15, 1985!
Regular Attendance Fee: \$375**

REGISTRATION FORM

Return to: BIO/TECHNOLOGY LOOKS TO THE NEXT DECADE, Nature Publishing Company, 65 Bleecker St., New York, NY 10012

Please reserve _____ places at BIO/TECHNOLOGY'S premier conference: **BIO/TECHNOLOGY LOOKS TO THE NEXT DECADE**, January 20-22, 1986 at \$375 each. (\$325.00 before Oct. 15, 1985!)

I understand that as a paid conference participant, I may attend all sessions, and receive all programs and materials.

New System 7300 Amino Acid Analyzer Plots, Labels, Calculates, Prints, Remembers

The System 7300 from Beckman features a new dual-channel data system that offers you important new capabilities for amino acid analysis.

It automatically labels each peak on the chromatogram with the name of the amino acid, so there is no need for time-consuming correlations with elution times. It calculates and prints out both 440 and 570 nm colorimeter signals for greater quantitative accuracy at picomole levels. And its floppy disc memory not only stores up to 40 analyses, but permits reassignment of baselines and reformatting of data.

Like the System 6300, the new System 7300 is a dedicated high-performance ion-exchange chromatograph featuring a single, prepacked stainless steel column operating at up to 3000

psi. It performs hydrolyzate analyses in a half hour, and physiological analyses in 2 hours. These results are guaranteed by Beckman, with detailed methods, applications back-up, and field service second to none.

No wonder the System 7300 has been received so enthusiastically by researchers the world over. For details, call your Beckman representative or write Beckman Instruments, Inc., Spinco Division, 1050 Page Mill Road, Palo Alto, CA 94304. Offices in principal cities worldwide.

BIO-RESPONSE FIRST IN CONTINUOUS PERFUSION CELL CULTURE

*The Key
To Success!*

BIO-RESPONSE, INC.

1978 West Winton Ave., Hayward, CA 94545
Telephone: 415 786 9744
Telex: 643476

Now you can synthesize DNA by β -cyanoethyl amidite or phosphotriester chemistries on a single system.

The Model 8600 DNA Synthesizer from Biosearch is preprogrammed for both synthesis protocols. Choose the one best suited to your needs and optimize DNA fragment length or synthesis cycle time.

If your requirements call for long DNA fragments, Biosearch's β -cyanoethyl amidite chemistry makes it possible to synthesize fragments well in excess of 150 bases with 250 O.D. or more of product—and a cycle time less than 6 minutes. These long fragments can be used to synthesize whole genes more easily by reducing the number of enzymatic ligations required, with a concomitant decrease in the number of purification steps.

Electrophoresis gel results for 150-base polynucleotide synthesized by β -cyanoethyl amidite chemistry.

On the other hand, if your need is for rapid, economical short-chain syntheses, Biosearch's new optimized phosphotriester chemistry can simplify the routine synthesis of oligonucleotide fragments up to 50 bases. You can expect reliable results in a cycle time of less than 7 minutes, with fewer steps and fewer reagents utilized.

And you're not limited to these two protocols. Since the 8600 is fully programmable, you can modify stored chemistries or develop your own as required. This

flexibility will allow you to keep abreast and take advantage of new advances in DNA synthesis.

Electrophoresis gel results for 35-base oligonucleotide synthesized by optimized phosphotriester method.

Whatever method you choose, you'll find that the 8600 makes it easier to obtain higher yields and faster cycles with automated mixed probe synthesis, automatic deprotection and cleavage, and simultaneous, four-column synthesis.

Biosearch also provides high-purity, high-stability reagents for both β -cyanoethyl amidite and phosphotriester chemistries. Moreover, each 8600 system is supported by a worldwide network of experienced technical personnel.

Biosearch—better ways to synthesize biomolecules.

MAGISCAN

THE TOTAL IMAGE ANALYSIS SYSTEM

In Counting, Particle sizing, Feature detection, Chromosome analysis, Magiscan provides the facts, leaving you free to make those other important daily decisions.

With its expanded input and output options and the increased speed provided by its inbuilt Winchester disc, Magiscan now has more power and flexibility to extract quantitative data from an even wider variety of images.

In addition to the comprehensive, easy-to-use general purpose software, a growing range of dedicated applications systems are now available, making Magiscan indispensable in any environment – clinical or industrial.

Whether you are involved in research or routine evaluation, contact Joyce-Loebl's team of applications specialists to find out how Magiscan can help you.

Joyce-Loebl, Marquisway, Team Valley, Gateshead NE11 0QW, England. Tel: (091) 482 2111. Telex: 53257.

Take a Break!

With the Nunc SlideFlask you will have the time.

If you want to microscope your cultured cells, the Nunc SlideFlask will meet your needs.

The cells are grown direct on the microscopy slide and after culturing, you simply break off the slide and place it in your microscope. By using the Nunc SlideFlask, you eliminate the trouble and loss of time involved in the transfer of cells to an ordinary microscopy slide or the cutting open of normal TC flasks.

The polystyrene of the culture slide is treated to ensure optimal cell growth.

Last, but not least, like all other Nunc TC flasks, the SlideFlasks are individually leak-tested.

Circle this ad for further info.

In the U.S. call toll-free 800-345-4707.

For quantitative autoradiography— $^3\text{H}/^{14}\text{C}$ micro-scales

The ultimate reference

Amersham now offers researchers convenient and economical products allowing tritium and carbon-14 labelled compounds to be accurately quantified in a wide variety of biological systems.

^3H and ^{14}C Micro-scales provide the precision and reliability required for these studies and will greatly facilitate the general use of quantitative autoradiography.

^3H Micro-scales are supplied in two overlapping activity ranges allowing accurate quantitation for autoradiographic exposures from 1 week to 12 months.

^3H Micro-scales are available in packs containing one multilayer block:

Polymer activity range	Code	Optimum autoradiography time
3-110nCi/mg	RPA.501	2-3 weeks

New – for receptor studies

0.1-16nCi/mg	RPA.505	4-6 months
--------------	---------	------------

^{14}C Micro-scales are supplied in packs containing either three or twenty 120 μm strips individually contained in glass tubes:

Polymer activity range	Code	Optimum autoradiography time
31-883nCi/g	RPA.504 (3 strips) RPA.504L (20 strips)	6 days

Hot on delivery...

...cold on arrival

When you order molecular biologicals from Pharmacia you'll find we're pretty hot on delivery.

We'll dispatch your order as soon as we get it, packing it carefully in wet or dry ice.

Now our enzymes are supplied in screw cap mini vials with new waterproof labels, and will easily fit into your centrifuge

tubes and freezer trays.

At Pharmacia Molecular Biology Division that's all part of the service. We realize that the success of an experiment depends on the quality of the products used and the speed at which you get them. With us you'll find that the only thing kept on ice is your product - not your

experiment.

Contact us today and we'll send you our free catalogue with details of over 800 molecular biologicals.

Pharmacia... your partner in molecular biology.

GUIDE TO AUTHORS

Authors should be aware of the diversity of Nature's readership and should strive to be as widely understood as possible

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an italic heading of about 50 words.

Letters to Nature are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in Nature. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or Washington. Manuscripts should be typed (double spacing) on one side of the paper only. Four copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc, should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc, should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts, in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963-65). The first and last page numbers of each reference should be cited. Reference to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be

Springer Biochemistry – your formula for success

ADP-Ribosylation of Proteins

Editors: F. Althaus, H. Hilz, S. Shall

1985. 271 figures. Approx. 585 pages
(Proceedings in Life Sciences)
Hard cover DM 248,-. ISBN 3-540-15598-8

This book presents the latest findings on the structural and functional consequences of the posttranslational modification of proteins with ADP-ribose monomers and polymers. Emphasis is placed on chromatin-associated ADP-ribosylation – a reaction which is ubiquitous in higher eukaryotes and appears to play a role in DNA repair, carcinogenesis, and gene expression during terminal differentiation. Important new findings on extranuclear ADP-ribosylation reactions, including those catalyzed by bacterial toxins, are also reported

K. Hayashi, N. Sakamoto

Dynamic Analysis of Enzyme Systems

An Introduction

1985. Approx. 350 pages
Hard cover DM 98,-. ISBN 3-540-15485-X
Distributions rights for Japan: Japan Scientific Societies Press, Tokyo

The dynamic analysis by computer simulation presented in this work will furnish biochemical researchers with a means for better understanding the *in vivo* behavior of an enzymatic reaction and its regulation at the molecular level. The analysis can also be applied to systems used in biochemical and biomedical engineering.

Population Genetics and Molecular Evolution

Editors: T. Ohta, K. Aoki

1985. Approx. 400 pages
Hard cover DM 118,-. ISBN 3-540-15584-8
Distributions rights for Japan: Japan Scientific Societies Press, Tokyo

A collection of reviews by international experts, this book introduces the evolutionary problems illuminated by the neutral theory as proposed by M. Kimura. The articles, written from the experimental as well as the theoretical standpoint, cover topics ranging from stochastic models to analysis of DNA data and sociobiology.

Primary and Secondary Metabolism of Plant Cell Cultures

Editors: K.-H. Neumann, W. Barz, E. Reinhard

1985. 147 figures. Approx. 400 pages
(Proceedings in Life Sciences)
Hard cover DM 188,-. ISBN 3-540-15797-2

Contents: From Metabolism and Osmotic Work to Totipotency and Morphogenesis: A Study of Limitations Versus Multiple Interactions – Primary Metabolism. – Secondary Metabolism. – Fermentation and Cryopreservation. – Herbicides – Plant Cell Culture – Future Perspectives – Subject Index.

Plant cell culture techniques are important tools in basic research on cell development and growth as well as on cellular metabolism of higher plants. This book surveys the most recent advances on the physiology of plant cell cultures and on their biotechnological applications, providing not only the state of the art but also the basis for a cautious evaluation of future directions in this rapidly developing area.

M. Luckner

Secondary Metabolism in Microorganisms, Plants, and Animals

2nd revised and enlarged edition 1984.
338 figures, 80 tables. 576 pages
Hard cover DM 124,-. ISBN 3-540-12771-2

This book is a summary of the biosynthesis, storage, transformation, and degradation of the most important groups of secondary products, as well as their significance for the producer organisms and for human beings.

T. L. Hill

Cooperativity Theory in Biochemistry

Steady-State and Equilibrium Systems

1985. 230 figures. XV, 459 pages
(Springer Series in Molecular Biology)
Hard cover DM 398,-. ISBN 3-540-96103-8

In this book, the author gives a unified treatment of the statistical thermodynamics of cooperative biological systems. The aim is to introduce, by a very large number of examples, methods that can be used to treat cooperativity in both steady-state and equilibrium systems.

Cellular Regulation and Malignant Growth

Lipmann Symposium

Editor: S. Ebashi

1985. 145 figures, 49 tables. IX, 503 pages
Hard cover DM 140,-. ISBN 3-540-15585-6
Distributions rights for Japan: Japan Scientific Societies Press, Tokyo

Contents: Gene Organization. – Regulation of Gene Expression. – Regulation of Cellular Activities. – Growth and Development. – Cell Transformation – Subject Index. – Author Index

Calcium and Cell Physiology

Editor: D. Marmé

1985. 94 figures. IX, 390 pages
Hard cover DM 128,-. ISBN 3-540-13841-2

This volume provides the basis for an understanding of the processes involved in the transduction of extracellular signals into changes of free, cytoplasmic calcium and of the molecular mechanisms underlying calcium-dependent intracellular functions. Leading experts have contributed up-to-date articles on the biochemistry of calmodulin and calmodulin-dependent enzymes, the function and regulation of calcium transport mechanisms, calcium-mediated cell responses, and the relation between calcium and cAMP.

Computers for British academics

The provision of computers in British universities has been generous while the rest of the system has been starved. The government should put computers on an equal footing with other equipment.

How can a university system (the British) generally supposed to be on the brink of collapse from penury be advocating expenditure of £47.5 million on the provision of supercomputers as a service for academic research? This will be one reaction to the report published this week (see p. 569). Indeed, many readers of the report will be surprised to learn that British universities already have access to two machines in the supercomputer class and that, moreover, there is a dedicated data transmission network linking all British universities with each others' machines and the two supercomputers. The explanation is that since the early 1970s, when the organization called the Computer Board was established, computing facilities at British universities have been dealt with separately from the other costs of academic institutions, and generously as well. During the past few years, funds in excess of £30 million a year have passed through the Computer Board's hands. Although the board, like the University Grants Committee, is a creature of the Department of Education and Science, it seems to have escaped lightly in the general rush to cut. The result is that British universities have reasonably good access to computing facilities. That is as it should be.

It is also right and proper that plans should be made now to keep the network up to scratch. Last week's report is both persuasive and arresting. The chief recommendation is that a decision should be made now to order a more advanced Cray machine, to be installed by 1988, and that the interval should be used for improving the data network to handle the extra flow of data. There are also sensible schemes for installing parallel processing equipment locally. Then, the committee argues, a decision should be made not later than the end of the decade on the specification of a second supercomputer specifically for academic use. There is the strongest possible reason why the British government (which will ultimately have to pay) should accept the committee's argument. Grumbles from elsewhere in the university system that £47 million could be better spent in different ways should not be allowed to carry too much weight. Even a university system generally in decline should be allowed to do some things excellently.

That should be the immediate response to a generally sensible report. The weakness of the committee's argument is chiefly administrative. That there should be a peer-review procedure for deciding who should have the right to bid for time on such supercomputer capacity as there may be makes sense. The idea that there should be a second tier of assessment to decide which problems have solutions of practical utility is more dubious. But the new proposal that there should be an entirely new board (euphemism for committee) with exclusive responsibility for the machines that happen, just now, to be called supercomputers makes no sense at all. This is a recipe for setting up a new committee whenever the evolution of computer hardware throw

up a radical novel generation of machines

The reason why this week's committee includes among its sponsors not merely the Computer Board but the Advisory Board for the Research Councils and the University Grants Committee, is that the sums of money involved are conspicuous. The Computer Board itself cannot hope to continue raising the funds it needs for general improvements and also to purchase supercomputers. But academic computers have come to stay, and like other scientific equipment will go on getting more powerful and (not as quickly) more expensive. The Computer Board itself should be recognized as an anomaly and subsumed within a larger organization. □

Worries about deficits

The failure of the US Congress to put the government's deficit to rights is serious for us all.

How much will the US deficit be in the financial year beginning on 1 October? \$200,000 million, the equivalent of \$700 for each man, woman, child and alien in the United States? Or 10 per cent above or below that figure? That is the untidy question the US government (the administration and the Congress in mutual cowardliness) has left for the rest of us to worry about. By now, the world knows that President Ronald Reagan rejected at the end of last month the plan of his party allies in the US Senate to save \$45,000 million by means of an oil import tax and the two-yearly staggering of social security revaluations, the Congress in panic settled for a mixture of cuts on budget spending that the appropriations committees may think it politically prudent to ignore.

Professional newspapers such as this must in prudence not stray too far outside their terms of reference. Liberally minded readers will acknowledge that concern for the workings of the educational system is proper, if only because that is what delivers recruits to the profession. Politically contentious though it may often be, even arms control is a permissible subject, partly because it has technical content, partly because research would come to an end if the cause of hard-headed arms control should fail. But why the US deficit? Because that too has technical content. And because the dice the US government is now tumbling could as certainly bring science and the enlightenment to a halt as an outright nuclear war.

Here is how the catastrophe may come about. For the past century, the United States has proved itself to be the most innovative and liberal of the mercantile economies of the modern world. The result is that people have become willing to lend money to US enterprises, knowing that in such an adaptable economy, the borrowers will probably make better use of the money than they could themselves. Moreover, they are usually confident that if things go wrong, they can hope to get their money back. Part of the reason for this confidence is that the US government historically has made only small demands on the US money system.

The big change is the deficit, at \$200,000 million roughly four per cent of the Gross National Product of the United States. The paradoxical situation has arisen in which foreigners finance a large chunk of industrial development, while the government in

Biological manuscripts

Contributors are reminded that, with the transfer of the Biological Sciences Editor to the Washington office, they should in future send **four copies of all manuscripts** offered for publication either (as at present) to London or to Washington.

Washington borrows its \$200,000 million a year largely from its own citizens and corporations. Interest rates are higher than they need be, given general confidence in the United States and the low rate of inflation over the past few years. The result is that the US dollar is artificially high compared with other currencies, which means that important sections of US industry, from agriculture to manufacturing, are competitively disadvantaged.

That the present circumstances are unstable is demonstrated by the fluctuations on the international currency markets. The threat to the US banking system occasioned by more than \$50,000 million of overseas loans is technically a separate issue, but one that could precipitate a loss of confidence in the dollar. Otherwise, there are two distinct ways in which the international community will deal with the deficit if the US government does nothing much about it: either people overseas will decline to keep on lending to the United States unless interest rates are further increased, in which case industrial production will further decline, the loss of confidence may go so far as to cause a flight from the dollar, in which case the currency will fall to where it should be, but corporations in the United States will be strapped for the cash they need to finance development. That is how the rest of the world sees the problem. In the United States, the prevailing sense, by contrast, is that trading partners are taking unfair advantage of the strong dollar, whence the widespread cry for protection from the rigours of free trade. The biggest danger now is that the Congress will listen more attentively to these voices than to the need to cut the deficit. The consequence, protectionism and counter-protectionism, could be just as serious as straightforward collapse. □

Action to follow

The US Food and Drug Administration plans to be more energetic. Time will tell if it succeeds.

Ms Margaret Heckler, Secretary of Health and Human Services in the US administration and, now that Mr James Watt has left the Department of the Interior, one of its most eager publicists, has embarked on a herculean task — that of preparing the Food and Drug Administration (FDA) for “the challenges of the twenty-first century”. More strictly, Ms Heckler has delegated the task to Dr Frank Young, director of the agency for the past year. Late last month, the two of them made public what the FDA calls *A plan for action*, a judicious blend of good intentions and more distant but even better aspirations. The temptation to make fun of this ingenuous document should, however, be repressed. Since the days during the Chinese cultural revolution when it was customary for Chinese public agencies to confess the errors of their past ways, and promise to do better in the future, there has been nothing like FDA’s vision of what it will become.

The starting point is tangible enough, the new procedures for the approval of new drug applications (NDA), published in final form in February. The intention is to simplify and accelerate the process of approving new drugs, partly by making FDA’s requirements of manufacturers more explicit, partly by admitting evidence gathered outside the United States in support of applications for generic drugs, for example. Along the same lines, a new set of regulations about Investigational New Drugs (IND) is about to make its appearance. Sensible proposals like these may not entirely meet the promise that the drug approval process may be shortened significantly from the present standard interval of 7–10 years, but they may at least prevent the further erosion of performance occasioned, among other things, by the increased sophistication of the testing procedures it is now possible (and prudent) to expect of applicants.

From that point on, the action plan becomes a good deal more fanciful. One proposal is that manufacturers submitting evidence in support of NDAs should be allowed to do so electronically, direct from their computer to another at FDA, thus doing away with the need to hire a truck to deliver the 100,000 pages of evidence which on the average accompany each application. The snag is that FDA has not yet equipped itself to receive these

electronic messages, and will be able to do so only when it can cheese the funds from elsewhere in its budget. The scheme for deepening the range of expertise available to FDA by appointing at universities a number of FDA fellows who would divide their time between research and the giving of advice is similarly still only a sentence or two in the plan. But FDA’s proposals for further improving the process of data collection and analysis as part of its surveillance of drugs already in use should be largely a matter of good housekeeping, and thus well within its own control. □

Geostationary blues

Governments are perplexed about the diplomacy of geostationary satellites.

A WORLD Administrative Radio Conference (WARC) of the International Telecommunication Union (ITU) must rank with anything on the subject of Canada as the surest way for newspapers to lose readers. But responsible newspapers acknowledge that, damn it, from time to time, ITU’s WARC’s have to be written about. The WARC now in session in Geneva, for example, is important: it will make assignments lasting a decade or more on radio frequencies and orbital positions for telecommunications satellites. Science writers have had to use all their ingenuity to make the subject comprehensible and, they fondly hope, interesting. And the biggest obstacles to their hopes are the names of the organization and of the conference and the technical problems involved.

The geostationary orbit, the circular path 36,000 kilometres above the Earth from which satellites appear to hover fixed over the same spot, is the hardest. The *Financial Times* made it sound quite cosy: “the most popular place for communications satellites . . . the ring in space which is home to about 80 operational communications satellites”. The *New York Times* disdained all technicalities and called it simply “the satellite belt”. How to brighten the name of the conference and the specialized agency of the United Nations which is running it? *Variety*’s “**Geneva Confab**” cannot be bettered, but neither can it be imitated. Other papers had to make do with phrases like “a six-week international gathering”. The *New York Times* did not mention the sponsoring organization.

Popularization is all very well but overdramatization is not. The need to make WARC interesting has pushed the newspapers into stating its purpose as unsnarling the “traffic jam in the heavens” or the “congestion over the Equator”. That is wrong, but the concept of a traffic jam is a poor metaphor. All the articles in which it appeared have then had to back away, explaining that there can be no physical pile-up and that the chances of collision in a path 265,000 kilometres in circumference are nil. Signal interference could be a problem, but even that is soluble with re-use of frequencies, higher frequencies and time-division multiplexing.

The real reason the conference was called is that the developing countries demanded it at the 1979 WARC. The United States, Britain and other industrial countries fought hard against it, but India insisted and, in the end, they had to give in. The developing countries demanded that they must have guaranteed access to places in orbit when they are ready, and so do not want the best positions to have been pre-empted by the industrialized countries. Equity in orbit is the problem, not congestion, and it will be tackled at two WARC’s — this summer’s and the second session set for 1988. The United States is fighting advance reservations on the grounds that the practice wastes spectrum and discourages innovation. But it concedes that it has to do something to placate the developing world’s legitimate gripe about the industrialized world’s monopoly on the orbit. This grows out of ITU’s long-established policy of awarding all frequencies on a first-come, first-served basis. The poorer countries do not like that either. About 90 per cent of the usable frequencies in the radio spectrum are occupied by 10 per cent of the 150 member countries of the ITU. □

Gene therapy

NIH/FDA dispute likely to delay research

Washington

THE US National Institutes of Health (NIH) have reached an uneasy truce with the Food and Drug Administration (FDA) in a dispute over regulation of human gene therapy. NIH's Recombinant DNA Advisory Committee (RAC) has spent the past two years drawing up a list of "points to consider" in evaluating gene therapy proposals, but a recent attempt by FDA to muscle in on the act had threatened a further lengthy round of reviews before experimental treatments could commence. Experimental gene therapies are now expected to be ready for trials before the end of the year.

The first gene therapy proposals will probably entail treating either Lesch-Nyhan syndrome or adenosine deaminase deficiency, both rare inherited diseases, by infecting patients' bone marrow cells with a retrovirus carrying the gene the patient lacks; the cells would then be replaced in the patient. *Points to consider*, drafted by a group under LeRoy Walters of Georgetown University, has already been published for comment in the *Federal Register* and a final version was to have been approved in September. Two weeks ago, however, FDA exercised its new authority as the official "lead agency" for biotechnology regulation and proposed that guidelines on gene therapy or deliberate release of engineered microorganisms should be reviewed by the new Biotechnology Science Board, a body that is to coordinate all federal agencies' interests in biotechnology. Meanwhile, FDA, as lead agency, would take control in areas where jurisdictions overlapped.

The Biotechnology Science Board has as yet no members, however, and it has not even been officially chartered. Faced with abandoning the past two years' work and having to start again, Walters' group has cancelled its September meeting.

The meeting at which FDA staged its coup attempt took place in the absence of NIH director James Wyngaarden. On learning of the FDA proposals, Wyngaarden met with FDA commissioner Frank Young (long rumoured as a future assistant secretary of health and unofficial "biotechnology czar") and secured an agreement that NIH would go ahead with *Points to consider* on the understanding that it applied only to NIH-funded research. The document will now once again be published for comment. As the first gene therapy proposals are likely to come from NIH-funded researchers, this measure should at least ensure that someone will read them when they arrive.

There are some points of substance in

the FDA/NIH dispute, besides the squabble over jurisdiction. RAC's meetings are held entirely in public, except when proprietary information is being discussed; FDA, in contrast, conducts its reviews in private. Wyngaarden plays down the importance of the dispute and says the confusion of roles has now been clarified: he points out that once bone marrow cells have been removed from the body and treated with a virus, they technically become "biologics" and so within FDA's purview. Historically, however, FDA has tended to turn a blind eye to *bona fide* researchers performing, for example, experimental diagnostic tests; it is not going to be so lax with gene therapy. Researchers will apparently have to seek approval for experiments from both NIH and FDA.

French science

Xenophobia out of fashion

THIS may not be an auspicious time to speak of an international stance in French scientific and technological relations — after President François Mitterrand has said "non" to star wars research, and after France has pulled out of European advanced fighter-plane project — but this is just what the French council of ministers was doing last week.

In a brief communiqué, the council (the French cabinet) said it wished to "intensify European cooperation", notably in relation to the Eureka project for new European high technology products, and would "reinforce our scientific and technological relations with the United States and Japan".

French research students are also to be encouraged to do their PhDs in collaboration with a foreign university, foreign researchers are to be given a better welcome in France than hitherto, and French scientific diplomatic representation abroad is to be reorganized, the communiqué said.

What this means in practice, however, is difficult to determine. The bid to improve research relations with the United States and Japan was "95 per cent exhortation", according to a French official, as it applied to industry, "over which we have little control", despite French industry's high degree of nationalization. However the intention was clear — to encourage French companies to learn from the Japanese and the Americans how to make a profit out of research: how to apply scientific know-how. For the feeling is that in certain sectors of the French economy, the government may have succeeded in putting researchers in touch with industry —

FDA officials say that is exactly the kind of over-regulation they are seeking to avoid. There also are criticisms of the way the NIH group under Walters, which is a subcommittee of RAC is constituted. One FDA official says that somatic cell therapy (the only sort contemplated in the near future) is analogous to many other medical procedures and so should be regulated similarly, by technical experts rather than by lawyers and bioethicists such as are found in Walters' group.

Points to consider describes the documentation needed to support a proposal for gene therapy: structure of the DNA construct, its purity, details of preparation, expression and animal studies; it also outlines the need for informed consent, measures to protect patient confidentiality and accurate information for news media. RAC is already considering one proposal that would allow it to bow out of areas where another agency has assumed responsibility for regulation; under this proposal, however, NIH would decide for themselves which areas to surrender.

Tim Beardsley

but there is some puzzlement in industry about what to do next.

In relation to universities, last week's communiqué may have more impact "as they take note of what government says". Jean-Pierre Chevènement, as a member of cabinet, has given the communiqué his backing, and must implement its recommendations. Thus it is likely that there will now be pressure on universities to design PhD courses in partial collaboration with foreign universities. How this might be done will be up to the universities, but the "habilitation" system, where universities must apply regularly for specific approvals to run postgraduate courses, would give the minister considerable power to influence the course of events.

Equally, it will be up to Chevènement and minister of research Hubert Curien to implement the recommendation that foreign researchers visiting France should be given better conditions of service. This means better grants for research students visiting France and fewer bureaucratic obstacles for more senior visiting scientists — despite the fact that last year all government-funded research positions became civil service posts.

As for French scientific diplomats, who are thicker on the ground in many countries than those of any other nation, there will be an attempt to "rationalize" their distribution and training, and, according to Paris officials, to cut costs. Many small countries enjoy the presence of a French scientific diplomat even though there is little research: such countries may lose their science counsellor, while larger countries may get more. Robert Walgate

Ocean Drilling Project

Britain still seeks for membership

WITH six weeks to go before the deadline, Britain is still scrambling to find 40–50 per cent of the £2.5 million fee needed to resume membership in the Ocean Drilling Project (ODP). As the crunch nears, Dr John Bowman, secretary of the Natural Environment Research Council (NERC), says the drive to participate has intensified. But so far, the roughly £1 million needed to take Britain over the top has not materialized. Britain was a member of the previous United States-led Deep Sea Drilling Program, but has not joined ODP for lack of funds.

"There is no doubt anywhere", says Dr Bowman, "of the scientific merit of ODP." Geologist Joe Cann, closely connected with ODP since 1975, described the importance of the new phase of the project. During the drilling of new holes, data will be gathered by sophisticated logging instruments (see *Nature* 316, 8, 1985); the holes will also be used for long-term monitoring of continuing processes beneath the sea floor, rather than as mere sources of rock samples. One of the most significant of the planned ODP projects, according to Dr Cann, is to intercept the deposits formed at the submarine hot springs that spew zinc, iron and copper sulphides into the ocean.

Mr Ed Nickless of NERC claims that 100 per cent of the membership fee could follow from talks now going on between the Department of Energy (DOE) and the oil industry, but not everyone is as optimistic. DOE, according to Dr Cann, is interested only in funding the drilling of holes in British waters that can then provide stratigraphic data of immediate relevance to British oil interests. The oil industry, which would prefer to do its own exploratory drilling, supports ODP as a source of ideas, not drilled holes. But Dr Cann points to the number of strategic ideas gathered from previous ODP trips that have been turned into exploratory tools for the oil industry in an "impressively rapid time — 5–10 instead of the usual 20–30 year span".

Refusal to dig deep into pockets also results from competition. British Petroleum, says Cann, looks at its direct competitors, primarily Exxon, and sees no reason why it should fund its country's involvement in ODP when the US company makes no comparable sacrifice. Additional industry money, therefore, could well not become available without an arrangement about taxation that would allow both industry and government to save face.

Dr Bowman defends the government's position, saying the shortfall of £1 million is a bigger hurdle than it may seem, particularly to observers in the United States, Japan and France, countries "with a lot more money to spend on the physical sciences". Besides, he says, there are many reasons to fund scientific research other

than the data gathered. But this, according to Dr Cann, is the real problem with British funding for the physical sciences in general and ODP in particular.

One case in point is British involvement in Antarctic research. So that a strong presence can be maintained there, the budget of the British Antarctic Survey (BAS) has been doubled in three years, from £6 million in 1982 to £12.96 in 1985. The results, Dr Frank Laws, head of BAS, is quick to point out, are easy to find — more staff, building programmes, satellite communication, heavy-cargo operations and funding of university research.

Yet these large sums of money earmarked for Antarctica do not give BAS unusual independence from NERC, says Dr Bowman. BAS just happens to be the primary research group funded by NERC which is involved in Antarctica. Because of ODP's work in the Weddell Sea, moreover, Dr Bowman says that rechanneling some of the Antarctic funds towards ODP would be appropriate. That amount, according to Dr Laws, would be a "significant contribu-

tion" that would still "not seriously affect BAS operations. By the same test, says Bowman, any sums taken from BAS would come nowhere near the elusive sum needed for British ODP membership.

Fiddling with budgets, says Dr Cann, can only hide the real problem. He claims that ODP decisions "have not been taken on a scientific basis at all," that "no real scientific presentation" has allowed, for example "an analysis of the relative scientific importance of ODP and BAS". The compartmentalization and politicization of such budgetary decisions is a description supported by the Royal Society Report on Geophysics, which sees Britain often taking on the role of poor relation in international efforts such as ODP. "Somebody, somewhere", says Dr Cann, "should make an impartial judgement" about the relative importance of physical science research as well as about ODP.

If Britain fails to find the full membership fee by 1 October, efforts will continue to join at a later date. NERC has put the ODP fee as second in priority to university research in its requests to the Advisory Board for the Research Councils, which will adjudicate in late November or early December.

Elizabeth Collier

UK research

All change at research council

In what may seem the nick of time, Britain's largest research council, the Science and Engineering Research Council (SERC), has found a new chairman. Professor E. J. W. ("Bill") Mitchell, head of

the Clarendon Laboratory at the University of Oxford, will begin a five-year stint on 1 October, only a month after his predecessor, Sir John Kingman, leaves to become vice-chancellor of the University of Bristol. At the same time, no fewer than six members of the 17-strong council will be replaced, at the end of their four-year terms, by newcomers.

Professor Mitchell is a solid-state physicist with a reputation as a forceful admini-

nistrator. His succession as chairman of SERC has been rumoured for some months. As a member of SERC since 1982, he will know of the unfinished business on the council's agenda. There is still no decision on the future of British collaboration with CERN, the high-energy physics laboratory at Geneva, while two important issues (support for astronomy and biotechnology) have been delegated to working parties that are likely to report only later in the year. The council's overall corporate plan is still being worked on while there is no certainty about the way which funds will be divided between the five research councils next April.

The newcomers include Mr David Shore, technical director of APV Holdings, who will become chairman of SERC's engineering board; Dr Charles Reece, director of research and technology at ICI; Professor Malcolm Jeeves, a psychologist who is now vice-principal of St Andrew's University; Professor Brian Fender, vice-chancellor of Keele University and formerly director of the Institut Laue-Langevin, who will be chairman of SERC's science board; Professor Robert Wilson, professor of astronomy at University College, London; Professor Donald Perkins from the University of Oxford, a particle physicist who will become chairman of SERC's nuclear physics board, and Professor David Davies from the University of London, an optical fibre specialist.

Supercomputing

Meeting British academic needs

A CENTRAL facility for advanced research computing is recommended this week by the report of a working party chaired by Professor A. Forty from the University of Warwick and commissioned by the Advisory Board for the Research Councils (ABRC), the Computer Board for Universities and Research Councils and the University Grants Committee (UGC).

The report proposes that the central installation should consist of the most powerful supercomputer available; the existing joint academic network (called Janet) should be enhanced for good communications; there should be a distributed system of other forms of advanced research computing to enhance local resources; and there should be a national organization to ensure effective use of resources, industrial and international collaboration and to stimulate new developments.

The cost of implementing the proposals will be about £47.5 million between 1986 and 1991. This includes £15 million for installation of the Cray X-MP multiprocessor array system at the Rutherford Appleton Laboratory, £8 million for high-speed lines and switches and £16.5 million for special purpose computers such as developments of ICL's DAP and GEC's GRID systems, which use distributed arrays of processors to perform operations in parallel. Running costs will be about £1 million a year. Purchase of a further supercomputer should be considered in 1988.

The report also proposes the machinery for running the facility: a board to advise ABRC, UGC and the Computer Board on advanced research computing needs and to award fellowships; and a peer review system to regulate use of facilities.

ABRC, UGC and the Computer Board must now decide whether they agree with the proposals and, if so, whether to allocate the money. ABRC is waiting for the individual research council's reactions to the report.

Recent advances in computing — vectorization and "parallel architecture" (simultaneous similar operations) — mean that the Cray 1 is 200 times faster than the VAX superminicomputer and 3,000 times faster and cheaper to use than the Atlas, the British supercomputer of the 1960s. Scientists in Britain currently have access to two supercomputers, the Cray 15 in London and the Cyber 205 in Manchester, linked by Janet. The London centre is now oversubscribed and Manchester is reaching saturation point. (There are also two DAPs in London and Edinburgh.) These supercomputers are not the most powerful models at present available.

The Forty report says the situation is different in other countries. In the United

States, the National Science Foundation programme started in 1984 involves the setting up of four supercomputer research centres ultimately to be linked by a national communications network. The government provides \$7–13 million a year to each centre and an equivalent sum is provided by industry, institutions and individual states.

In Japan, the seven main universities have a "special relationship" with one of the three major computer manufacturers (Hitachi, NEC and Fujitsu). Tokyo University, for example, has a Hitachi 5-810/20 supercomputer and Kyoto University a Fujitsu VP1100, both having replaced scalar machines at no extra cost. Other European countries such as France and West Germany are rapidly installing supercomputers and providing coordinated research programmes.

The new report's assessment of British needs is based on a questionnaire sent to

more than 400 individuals and scientific organizations and a detailed review of each subject provided by specialists in the field. The survey conclusively shows the need for a wide range of supercomputing facilities in astronomy, physics, earth sciences, engineering, biological and biomedical sciences, economics and information science.

Apart from the rapid understanding of many diverse scientific processes, the report emphasizes the use of supercomputers in industrial applications such as design and testing of pharmaceutical products using simulations, simulation and testing of aircraft engines and oil field modelling.

According to the report, there are compelling reasons for a coordinated and ambitious plan for the development of supercomputers in research in Britain. Haste is urged if Britain is to remain a world leader in the computer arena. Whether the bodies that commissioned the survey will agree, and if so, where the facility will be built and developed, remains to be seen.

Maxine Clarke

European training

Commission plan for mobility

Brussels

A FURTHER boost is to be given by the European Economic Community (EEC) to cooperation between European industry and academic institutions. The European Commission is advocating an 80 million ECU (about £44 million) four-year programme to stimulate on-the-job advanced training for students in companies in European countries other than their own. The scheme will also support exchanges between academics and those employed in new technology industries.

Later this year, the Commission hopes to persuade the ten ministers to agree to the four-year initial phase (1986-89) of the COMETT programme (Community in Education and Training for Technology).

Following in the steps of other Community initiatives such as ESPRIT, BRITE, the stimulation programme steered by the CODEST committee and the plan for transnational development of support in innovation and technology transfer, the programme will concentrate on new technologies, where it is felt that there is a particular need for more investment in training to keep up with rapidly changing technology.

The proposed programme would include exchange schemes between people in industry and universities as well as joint training projects between companies in different countries and the setting up of a European liaison network between university/industry training partnerships (UITPS).

Specifically, the Commission intends to start by offering some 2,000 six-month grants worth 4,000 ECU each for students

to train with a company in another Community country, with 3,000 places in 1988 and 5,000 in 1989.

A smaller number of grants (50 in 1987, to be doubled in 1988 and again in 1989) of 9,000 ECU would be available to university teaching staff willing to spend two or three terms in one year broadening their industrial experience in a company in another EEC country.

The Commission hopes there will be two kinds of joint training projects, one focusing on specific topics where skill is scarce and one designed to improve the flow of research results between industry and the universities. The Commission is prepared to pay 35 per cent of the cost up to a maximum of 500,000 ECU. It is also prepared to cover up to half the cost (a maximum of 400,000 ECU) for multilateral university/industry projects aimed at using new technologies in education and training itself. The COMETT team would also carry out a feasibility study for a European technological open university.

Some Community money would also be set aside (50,000 ECU a year) to cover half the running costs of promoting links between university/industry training partnerships, forming a Community-wide network coordinated by the Commission that would link up 40 UITPS in 1987 and 150 by 1989.

Finally, the Commission would also sponsor round-table meetings to bring industry and university together and would set up a database on cooperation, monitoring and analysis of Community trends and issues in advanced training.

Anna Lubinska

Space physics

NASA told to be more active

Washington

THE US National Research Council has told the National Aeronautics and Space Administration (NASA) to reverse the "long-term decline" in Solar System space physics, and has helpfully prescribed an ambitious series of projects to accomplish the task. The council's report* on the subject urges NASA to give highest priority to the International Solar Terrestrial Physics programme (ISTP), for which launches should start in 1989.

This influential support for ISTP should be music to the ears of NASA's partners in the project, Japan and the European Space Agency (ESA); three years ago, NASA infuriated European scientists by reneging on a promise to supply a satellite for the International Solar Polar Mission (now known as Ulysses). NASA officials now say there is "a reasonably good chance" that the agency will include funds to start work on ISTP in its budget request for fiscal year 1987 which NASA will finalize by 15 September.

The other two missions vying with ISTP for inclusion as a 1987 "new start" are

TOPEX (a satellite to measure ocean topography) and CRAF (Comet Rendezvous and Asteroid Flyby); the latest betting at NASA headquarters is that TOPEX and either CRAF or ISTP will be approved. In addition, the 1987 budget request is likely to include work on the mirror for AXAF, the Advanced X-Ray Astronomy Facility. By developing AXAF in stages, NASA hopes to avoid the embarrassing cost over-runs that plagued development of the Hubble Space Telescope.

The National Research Council Report, chaired by Stamatis M. Krimigis of the Applied Physics Laboratory at Johns Hopkins University, assumed a plausible (if hopeful) budget for Solar System space science of \$400 million by 1987 (in 1985 dollars); the current figure is \$300 million. NASA officials say the projects described in Krimigis's report are well justified and that it will be for Congress to decide how many will be funded.

Krimigis's report gives its blessing to the Upper Atmosphere Research Satellite, now being developed, and urges "immedi-

ate" funding for development of the Solar Optical Telescope, a 1.25-metre-aperture instrument that would form the basis of a solar observatory on the space station. It also wants to see a start on a long talked-about solar probe that would approach the Sun to within 4 solar radii; work should begin immediately on a heat shield for the mission in time for a possible launch in 1995. Looking further to the future, the committee gives its blessing to a solar polar orbiter that could be launched by the end of the century if a suitable propulsion system is developed.

Besides the highly visible major missions, the research council endorses an expansion of ground-based modelling and theoretical work in plasma physics; one goal is to provide an account of how disturbances on the Sun affect the heliosphere and thence the magnetospheres, ionospheres and upper atmospheres of the Earth and planets. There should also be a series of Explorer payloads, according to the committee, starting in the 1990s, to investigate Solar System space physics.

Besides being extremely colourful, the report is admirably specific in its recommendations. The committee's purpose might well be to avoid the fate of the 1980 Kennel Report on the same subject, on which the committee plaintively notes there has been "no significant progress" because of budget constraints.

*An implementation plan for priorities in Solar-System space physics (Executive summary) Committee on Solar and Space Physics, National Research Council, 1985.

European research

EEC plans risk management

Brussels

THE European Commission has suggested to ministers of the European Economic Community (EEC) that 15 million ECU (European Currency Units, 1 ECU = £0.60) be provided over the next five years for research into the prevention, prediction and management of industrial accidents involving chemicals such as those that occurred in Seveso, Italy, in 1976 and last December in Bhopal, India.

Part of the new five-year 150 million ECU programme that also includes environmental protection and climatology, contracts on major technical hazards, to which the Community would contribute half the costs, will complement research already under way at the commission's own Joint Research Centre. These contracts will involve both industry and research institutes. It is hoped also to involve researchers from outside the EEC.

The aim will be to improve the scientific foundation of risk analysis by studying the physical and chemical phenomena of dispersion, runaway reactions and other causes of chemical accidents. There will also be an attempt to improve or replace hazardous processes, to improve safety technology, and to detect and mitigate high-risk situations. The Commission proposes that a start should be made on the transportation of bulk hazardous substances and on hazardous production processes.

The proposal would strengthen EEC

legislation sparked off by the Seveso disaster, when highly toxic dioxin was spewed accidentally over a north Italian town. The directive on the prevention of major industrial accidents came into force in 1981, but its implementation has posed difficulties for the member states.

In the environmental part of the research programme, for which 65 million ECU has been set aside, emphasis will be placed on health and ecological effects of pollution (particularly the deterioration of historic monuments), air, water and soil quality (including the impact of farming practices), waste, chemicals assessment (including the development of methods to avoid using vertebrates in toxicity tests) and noise. Emphasis will be put on advanced pollution abatement technology, in the hope that the outcome will also improve industrial competitiveness and employment prospects.

The Commission also intends to promote training in environmental sciences. Finally, 250 million ECU will be set aside for the second phase of a programme of long-term climate research. Work will continue on the physical basis of climate modelling, seasonal forecasting of European climates, climate sensitivity, effects of changes in atmospheric composition (via carbon dioxide and trace gases) and changes in land-surface properties, detection of climatic change and climatic impact on land, water, vegetation and marine resources.

Anna Lubinska

Polish protest (cont'd)

POLAND's unofficial Social Committee for Learning, SKN (*Nature* 314, 123; 1985) has been quick to respond to the enactment, on 25 July, of the government-sponsored amendments to the 1982 Higher Education Act. A copy of SKN's irregular news bulletin *Servis informacyjny SKN*, dated 28 July, presents a reprint of the official announcement of the new law with the "tentative summary" of the effect of the changes, prepared by the Main Council for Science and Technology, the official representative body of the universities.

In the opinion of the Main Council, "without embarking on a major discussion of the motives and grounds for the proposed changes, they are clearly aimed at the creation of a legal framework for the direct and centralized direction of all matters relating to higher education in Poland, not only in questions of its organization but also in a wide range of questions of cadre policy and scientific research, not excluding legalized para-censorship".

The SKN bulletin also notes, however, that in the opinion of Deputy Jarema Maciszewski, who presented the bill to the Sejm: "The proposed changes do not contravene the idea of university self-government, but simply restore its purely academic character".

Vera Rich

Japanese psychiatry

Mounting pressure for reform

Tokyo

JAPAN'S mental health system is once more under fire. Representatives of the International Commission of Jurists (ICJ) and the newly formed International Commission of Health Professionals (ICHP) who came to Japan on a fact-finding mission in May published their first report last week. It makes disturbing reading.

The present "structure and function of the Japanese mental health service" is summed up as "conducive to inappropriate forms of care and serious human rights violations on a significant scale". As examples, the report lists "unacceptable conditions of overcrowding and poor nutrition which may lead to physical deterioration of patients and high rates of mortality; physical abuse of patients; exploitation of patient labour; unjustifiable detention; the inability of hospitalized patients to communicate with friends and family members outside the hospital or to receive visits under reasonable conditions".

That description may seem more fitting to a prison camp than a place of care for the sick but there is, regrettably, evidence that such conditions have existed in Japan. The report does not, however, mention specific cases; its avowed aim is to comment on the "overall system" rather than on individual occurrences.

Had specific cases been taken up, there is no doubt that the Utsunomiya hospital would have been first on the list. The hospital became the subject of major national scandal last year. It seems that violence and confinement were regularly used to subdue patients, mail was censored, meetings with outsiders prevented, patients forced into labour, unqualified staff employed, money embezzled and patients admitted and detained illegally.

Such at least were the more minor allegations made against the hospital staff; the serious allegation was that two patients were beaten to death, one for trying to escape. The hospital superintendent is now in prison but the case is far from cleared up. Independent psychiatric examinations after the scandal resulted in 40 per cent of the hospital patients being discharged; but there are accusations that a significant number of patients are still being unnecessarily detained.

Within the past few weeks, similar accusations have been made at another hospital, the Otaki hospital in Chiba prefecture. Once again there are allegations that a patient has been beaten to death by hospital staff. And two patients hospitalized after family quarrels and kept for long periods in locked wards have been judged sane by independent psychiatrists.

Despite the publicity given to these incidents, it would be quite wrong to think of

them as typical; most doctors and hospital staff are conscientious and see these abuses as "isolated exceptions". But what the ICJ/ICHP report makes clear is that the present Japanese legal system makes it all too easy for abuses to occur, however conscientious the average doctor may be — without reform there will continue to be "isolated exceptions". The major driv-

ing force behind the hospital abuses is undoubtedly greed. More than 80 per cent of psychiatric beds are in private mental hospitals and huge profits can be made. The temptation to cut patient care and hospital costs is great, especially as government supervision is minimal.

The report makes a number of specific recommendations for reform. Most notably, it is suggested that all cases of "involuntary hospitalization" be subject to independent review. As a recent government survey has shown, 93 per cent of inpatients are confined against their will (against just 5 per cent in the United Kingdom) and 80 per cent are confined under Article 33 of the Mental Health Act. This article allows the superintendent of a mental hospital to commit a patient indefinitely without the patient's consent and without the opinion of an independent psychiatrist provided the person responsible for the patient gives consent.

Clearly, as hospital profits require full beds, it is all too easy for a hospital superintendent to be tempted to misuse his powers. Stories have even been circulated of hospitals rounding up tramps from the streets of Tokyo in order to fill their wards; although such stories have never been substantiated, the fact that serious newspapers publish them at all suggests that public confidence in mental institutions is not high.

The report further suggests that an independent review tribunal be established, mental hospitals be regularly inspected and patients have right of access to the tribunal. At present, Article 38 of the Mental Health Act provides that "the administrator of the hospital may set necessary limits to the action of any in-

mate...". This extraordinarily wide power given to the hospital administrator has allowed censoring of mail, and refusal of visits and independent psychiatric assessment. Some patients have virtually been turned into prisoners without rights.

The report sees the general thrust of reform as towards the "community care" style of psychiatric treatment now espoused (if not adequately supported) in the West: that means short periods of hospitalization, provision of out-clinics attached to health centres, sheltered "half-way" houses, home visits by health workers, patient clubs, help in finding employment and so on. Such measures contrast starkly with the present Japanese system of large hospitals located in remote regions where land is cheap and long hospitalization periods. And while mental hospital populations are declining in the United States and Britain, those in Japan are increasing.

The report does not seek, however, to impose external standards of care on Japan and repeatedly stresses that changes need to be adapted "to meet the needs of Japanese society". Nor does the report paint a universally black picture. Recognition is given to psychiatrists, health officials and concerned citizens who are already actively trying to bring about change, and mention is made of innovative mental health programmes already in existence.

Given the clear aim of the report to be constructive, the response of the Japanese government has been very disappointing, to say the least. All the government has done is to question whether the report was truly the unanimous opinion of ICJ and to dispute the view, presented in the ICJ/ICHP report, that a previous critical report from the World Health Organization had not led to any changes in Japan's mental health policy. The first question was based purely on rumour and was quickly dismissed by ICJ. The second appears to be mere nitpicking. Not one of the major recommendations of the WHO report has been implemented. Given that it was published in 1968, astonishingly little progress has been made.

Hopes for change in the future are not bright. Considerable stigma is still attached to the mentally ill and it is unlikely that public support for reform will grow rapidly. A number of hospitals have introduced reforms but few of them are in the private sector, and without government backing, change will be slow. The major impetus for reform seems to come from foreign critics. The problems of Japan's hospitals are, at least, becoming internationally known. One of Japan's foremost campaigners for reform of the Mental Health Act, lawyer Etsuro Totsuka, spoke for the first time at a meeting of the British reform group MIND a few weeks ago. The ICJ/ICHP report will be submitted to the UN Subcommittee on Human Rights in the near future. **Alan Anderson**

Catastrophism still unexplained

SIR—Despite Napier and Clube's frequent (and frequently changing) statements on the nature of terrestrial catastrophism and possible extraterrestrial causes, they were not the first to point out that the Sun's motion in the Galaxy might be the causative agent, as stated by John Maddox (*Nature* 315, 627; 1985). At least one earlier suggestion of this idea was a quite excellent paper by K.A. Innanen and colleagues entitled, "The interaction of the spiral density wave and the Sun's galactic orbit"¹ which appeared in 1978. That paper noted and displayed a figure showing the coincidence between galactic plane crossings and the boundaries between geological periods on the Earth.

Also, if I remember correctly, Napier and Clube² suggested that the important mechanism would be the Sun's passage through galactic spiral arms which happens every 250 Myr or so, as opposed to galactic plane crossings which occur every 33 Myr.

The periodicity in the terrestrial extinction record is certainly in grave doubt at this time. But I suggest that if there is any real periodicity it is most likely associated with a period of which we are already aware, that is the Sun's epicyclic z-motion about the galactic plane, rather than any of the artificial constructs we have seen suggested, such as the hypothetical death star or planet X. However, the problem of finding the extinction mechanism which might be associated with the Sun's epicyclic motion still remains unsolved.

Conference costs

SIR—It cannot be good that British scientists are unable to attend conferences in their own field held in their own country, a situation that now prevails.

American colleagues report to me that they come to conferences in the United Kingdom in the hope of meeting their British counterparts, only to find that apart from invited speakers, British academics, both staff and graduate students, are largely missing.

The cause is simple: *money*. Conference fees are now enormous (to pay presumably for the air fares of the overseas speakers), and there was even an institution which ran a "hundredth birthday" symposium from which its own staff were excluded unless they paid a large fee! At the same time, in order to stay afloat, the universities that host the conferences are

charging "economic" (meaning swinging) rates for accommodation and meals, while they and other publicly funded institutions are unable to reimburse anything but the smallest sums for attendance at conferences. (My own institution now pays a maximum of £40 a year, barely the train fare to London, and this by national standards is generous.) Erosion in the real value of salaries makes it difficult, particularly for younger staff with mortgages and children, to find the several hundred pounds that a conference may cost out of their own funds. British scientists are thus deprived of the international contacts that they should have, and of much needed opportunities to keep abreast of their fields.

Remedies are not so simple, but here are two suggestions: as all universities are levying enormous accommodation charges on each others' staff, they are in effect taxing their own staff for carrying out a necessary part of their work. An immediate convention should be set up by the Committee of Vice-Chancellors and Principals allowing British academics to be charged for accommodation at cost when attending a meeting at another university in this country. Second, the Royal Society should consider extending its system of grants for attendance at conferences overseas to include attendance at conferences in the United Kingdom.

Value-free science

SIR—The idea of value-free science has been defended by two of your correspondents over the past several months, Bernard D. Davis (*Nature* 311, 294; 1984 and 315, 176; 1985) and M. Hammerton (313, 343 and 315, 536; 1985). Unfortunately, they have not satisfactorily answered the points raised by Mark Diesendorf (313, 92 and 314, 666; 1985).

Davis's illustration of the risk of fallout from nuclear weapons provides an excellent illustration of the different ways in which values are embodied in science.

Research related to nuclear weapons and fallout comes overwhelmingly from the governments of nuclear weapons states. That means that these governments influence the direction of scientific development. After all, values are involved in choosing a particular facet of the world to study and about which to formulate knowledge.

Knowledge about nuclear weapons and fallout is selectively useful to the governments of nuclear weapons states because they are the ones who can hire experts to apply it. Community groups do not have much use for nuclear science. Scientific knowledge is value-laden because it is selectively useful to different social groups.

Knowledge about hazards from fallout has often been used to justify continued nuclear weapons testing, ignoring the fact that the "benefits" of testing accrue to governments and militaries while the hazards literally fall on many people who obtain no benefit at all. Much scientific knowledge is value-laden because it serves to justify policies and practices of certain groups. Another example is the setting of "acceptable" levels of exposure to radiation: acceptable to whom?

In the past, defenders of nuclear technology have often adopted the hypothesis that there is a threshold beneath which radiation exposure poses no risk to health. This illustrates how the content of scientific knowledge can embody values.

These and other points are elaborated and illustrated in my study *The Bias of Science*.

It is futile to try to argue away or exorcise values from science, since this only obscures the role of the social context of science. More appropriate is the aim of making the values open and apparent, so that the direction and use of science can be a subject for public debate.

Paul Rosbaud

SIR—The Houghton Mifflin Company will publish in 1986 a book about Dr Paul Rosbaud, scientific adviser to Springer-Verlag in Berlin until 1945. After the Second World War, Rosbaud became associated with various scientific publishing activities in Britain until he died in 1963. Copies of letters, papers and so on associated with Rosbaud would be deeply appreciated by the undersigned. Particularly welcome would be any reminiscences about Rosbaud before 1946.

Faith in God

SIR—In his review of Hugh Montefiore's book *The Probability of God* (*Nature* 315 353, 1985), John Maddox seems to imply that religious belief is almost some kind of moral and/or mental inadequacy. I would say rather that belief in God—any god—must ultimately be irrational, for it involves a step of faith. If belief were to be rational, that is, if the existence of God could be proved, then it would be meaningless, for surely a god whose existence can be proved by the activities of man is no god at all.

THE LANGMUIR-BLODGETT INSTRUMENT

If advanced molecular electronics is your field of interest, this is the Langmuir-Blodgett instrument for you. KSV offers state of the art thin film technology of tomorrow... today. The new KSV 2200 LB monolayer laboratory achieves the performance and reliability demanded by the fabrication of the most sophisticated LB-films.

The Automatic Film Collector system was developed to allow unsupervised deposition of ordered layers of LB-films, while consistent quality is guaranteed by the microprocessor-controlled Dynamic Film Control system.

The requisite ultra-clean atmosphere is created by the rugged laminar flow enclosure.

To make things even better, you have direct access to the KSV 2200 LB system from your personal computer through a standard RS-232C serial interface. Convenient and rapid data acquisition and processing with KSV software means flexibility and fast analysis of results – with the swiftness and accuracy you have only dreamed about. You can concentrate on the information, not the instrumentation.

Discover the state of the art thin film technology with KSV 2200 LB – the leader in Langmuir-Blodgett films.

Towards the quantum computer?

The Turing machine, an abstract computer conceived half a century ago as a test of what might be computable, has been overtaken by an idealized quantum computer, which also has drawbacks.

THE notion of the quantum computer means different things to different people. At one extreme are the hardware engineers, the people who behave (successfully) as if for every physical phenomenon there is at least one practical device. IBM's recent disappointments with Josephson junctions apart, these people know in their bones that the quantization of magnetic flux, as within closed loops of superconducting material, will one day be the basis of a memory storage element. The other extreme is the conceptual, typified by those who worry over the correspondence between the elementary units in which information is handled in computers and the quanta of the physical variables that characterize real physical systems.

A whole string of more substantial questions obviously suggest themselves. To what extent, for example, is the accuracy of a computer calculation limited by the deterministic uncertainty of quantum mechanics? Whatever the care with which signals are processed so as to encode a memory cell with either the digit zero or unity, the result cannot be entirely certain while the uncertainty principle remains in being. This is not a practical difficulty for the time being, while the scale of the most tightly-packed electronic components is measured in some hundreds of interatomic distances, but in due course the uncertainty principle must determine the limits to which it will make sense to carry very large-scale integration.

Meanwhile, but for a different purpose, Dr D. Deutsch from the Department of Astrophysics at the University of Oxford (*Proc. R. Soc. A* **400**, 97; 1985) has given what seems to be a way of describing the properties of a quantum computer which, among other things, has the virtue of showing the physical nature of the computing process. Quantum computers, it appears, are potentially more powerful in important ways than even that computational paradigm known as a Turing machine.

A Turing machine (first described by the late Dr Alan Turing nearly half a century ago) is, it will be recalled, a stripped-down computer, consisting only of an indefinitely long memory tape and a device (which would now be called a processor) whose state at any instant depends both on its previous state and on the most recently read item of information on the tape. On the assumption that the informa-

tion on the tape includes what would now be called the program as well as the input data, the pedagogical (some would say "heuristic") value of the Turing machine is to demonstrate the power or the limitations of the computing process, depending on one's point of view. Turing's purpose, in 1936, was to assert that such a machine, however rudimentary it might seem, could compute anything generally held to be computable. Deutsch, to be fair to J. Church (*Am. J. Math.* **58**, 435; 1936) calls this the Church-Turing principle.

Put like this, the principle sounds like a tautology. Deutsch argues that the tautology conceals a physical reality. The output datum of a computation will be a function of the input datum, so that the question of what may be held to be computable boils down to specifying the class of functions that can be realized by a Turing machine. Deutsch points out in passing that all that such a machine can do in practice is to make a map of the set of all the integers on itself, which is not exactly the same as defining the functional relationship between input and output (a point of some importance when so many people are interested in chaos, where a small change of an input variable may mean a very large change in the corresponding value of the output). More tellingly, Deutsch goes on to argue that the truth about the class of computable functions, or of conceivable algorithms, is that they are physically realizable. That mathematics is the handmaiden of physics is not an accident. And so Deutsch puts the "Church-Turing principle" in the form "Every finitely realizable physical system can be perfectly simulated by a universal model computing machine operating by finite means".

What kind of machine is that? Luckily, the formalism is not difficult, and can be put in words. The machine has a memory, which may in principle be infinite, but only one bit is involved at any step. There is a processor whose internal (quantum) state represents the progress of the computation. And there is an input/output tape which can move only one step (forwards or backwards) at a time, and whose position is an observable (in the sense of quantum mechanics). The evolution of the system as a whole from one step in the computation to the next is determined (as in ordinary wave mechanics) by the operation of some unitary operator on the state vector of the system lying within some appropriately catalogued Hilbert space. Although the dimen-

sionality of the problem will be dominated ordinarily by the number of memory cells, contributing that many powers of two, the problem is simplified because the elements of the unitary transformation matrix are themselves simplified by the requirement that the tape should move by only one step at a time, and that only one memory cell should be involved. One computer will differ from another in the structure of the unitary transforming matrix.

The formalism may be describable in words but the details show that the theory hangs together. Deutsch shows that a quantum computer (as defined) can carry out any computation of which a Turing machine is capable but that, because the elementary unitary transformation can mix together quantum states in ways that have no classical analogues, the universal quantum computing engine can yield results beyond the ken of classical machines.

For one thing, a quantum computer should be capable of generating true random numbers and not simulations thereof. (Proud custodians of new hardware who are convinced that their classical machines will generate random numbers for them had better read the 178 pages of *The Art of Computer Programming* Vol.2, in which D.E. Knuth explains why the programs purporting to give random numbers at the push of a button cannot be trusted.) Deutsch gives two sample programs. He goes on to show how to write a program (for a still non-existent quantum machine) to verify Bell's inequality about the essentially quantum character of quantum correlations. There are even a dozen lines of Algol 62 which simulate the Einstein-Podolski-Rosen experiment.

The interesting part of the argument concerns the interaction of the quantum computer with the outside world. To make this non-existent machine function, it is necessary that its initial state should be "prepared", in the sense of quantum mechanics, to be in some well-defined state, which is the same thing as saying that it has zero entropy. Deutsch himself points out that the third law of thermodynamics would make such a state inaccessible in finite time, goes on to say that the evolution in time of a small part of the Universe (such as a quantum computer) may be determined by a non-unitary transforming matrix and declares that it is of practical as well as of philosophical importance to learn what the rules are. Nobody will quarrel with that.

John Maddox

Molecular genetics

Introns continue to amaze

from Andy Flavell*

IN 1977 Joe Sambrook wrote a *News and Views* article in *Nature* entitled "Adenovirus Amazes at Cold Spring Harbor" in which he described the first experiments demonstrating RNA splicing¹. Since then we have learned that most eukaryotic and some prokaryotic genes contain intervening sequences (introns). Time has mellowed the initial astonishment but as we become accustomed to each new finding in this field, another fresh observation startles us out of our complacency. We have learned that some introns can remove themselves from precursor RNAs without recourse to proteins², others encode proteins which aid this process³ and many form circular excision products, some with 'strange' lariat structures^{4,5}. Those who thought that the flow of startling observations would diminish will have to reconsider in the light of two sets of results, one of which is reported on page 641 of this issue⁶.

A big problem for molecular evolutionists has been the question of why genes have evolved in this manner⁷. One major school has suggested that introns have existed as long as recognizable genes⁸⁻¹⁰ and initially represented the junctions between small units of genetic information. Long precursor RNAs could self-splice to create assortments of these units, successful combinations being rewarded in the normal Darwinian manner. There were early attempts to argue that introns were vestigial mobile elements which had been transposed into genes¹¹⁻¹³ but no evidence emerged to support this notion. Recent results on yeast mitochondrial introns may, however, provide hard evidence that introns are far from passive sequences, with some perhaps able to ensure their survival by transposition to new locations^{6,14,15}.

Michel and Lang now demonstrate sequence homology between certain fungal mitochondrial messenger RNA introns and the reverse transcriptase genes of retroviruses⁶. Reverse transcriptase is the key enzyme in the retroviral life cycle; it converts the viral RNA into DNA, which becomes incorporated into the host genome. Michel and Lang have compared the predicted amino-acid sequences of the long open reading frames of four class II introns of fungal mitochondria with those of the highly conserved regions in retroviral polymerase genes (Fungal mitochondrial introns are divided into two classes based on the presence of one of two sets of short sequence blocks that are

thought to determine their secondary structure in RNA^{16,17}). These regions are conserved between the *pol* genes of all known vertebrate retroviruses and retrovirus-related elements in yeast, plants and insects^{18,19}. The new work shows that each of the homologous segments that unite these introns are related to a corresponding conserved segment of the retroviral *pol* genes. The order of segments is conserved with a few differences in gap size between them. Lastly, the ten diagnostic predicted amino acids, which are virtually all present in *pol* genes, are similarly conserved in the class II open reading frames. It is thus likely that these open reading frames encode proteins that are related to reverse transcriptase.

What is known about the gene products of these class II open reading frames? The answer is quite a lot and none of it points to their encoding reverse transcriptase. The a1 intron of the *oxi-3* gene (one of the four open reading frames) encodes a 'maturase', which has been elegantly demonstrated by Slonimski and coworkers to be necessary *in vivo* for the splicing out of the intron that encodes it²⁰.

It seems unlikely that a DNA reverse transcript of an intron participates in the removal of that intron from a precursor mRNA; is it more likely that the open reading frame gene product possesses both reverse transcriptase and maturase activity? There is some evidence to suggest that the maturase activity is not critical to the splicing event. Class I and class II introns are probably all spliced by a mechanism closely related to that of the self-splicing ribosomal RNA introns of *Tetrahymena*^{21,22}. It is thought that maturases aid the alignment of precursor RNAs, which then splice auto-catalytically^{6,21,22}.

Other nuclear genes have been identified in yeast that are necessary for splicing of mitochondrial introns in this fungus. A dominant mutation (probably a mis-sense point mutation) in one of these, *NAM-2*, cures a splicing deficiency resulting from the inactivation of the b4 maturase (which is required for splicing of the b4 intron of the *cob* gene containing it and also of intron a4 of the *oxi-3* gene²³). The *NAM-2* mutant gene requires a gene product of the region containing exon 4 and intron a4 for this action. These data show that maturases participate in splicing at some stage, but under some conditions a particular maturase is dispensable and there is an independent requirement for other gene product(s). They do not show what enzymic activity maturases possess. To complicate the picture further, if the wild-type *nam* allele is totally inactivated, the mitochondrial genome is annihilated,

forming cytoplasmic *petite* mutants²³.

Michel and Lang argue that maturase function may be an accessory activity, regulating the level of the intron gene product, the major function of which is the maintenance of such introns by dissemination through the mitochondrial genome. Seen in this way, the fungal mitochondrial genome is an environment being exploited by an autoregulated class of mobile genetic elements. This is perhaps taking speculation a bit too far on the sole basis of amino-acid homologies. What is obviously required is the demonstration of reverse transcriptase activity in yeast mitochondria and, one hopes, from *in vitro* constructs containing these class II maturase genes. It will also be important to demonstrate transposition of class II introns, if possible. The authors cite two pieces of circumstantial evidence implying the presence of reverse transcriptase activity in fungal mitochondria — the occasional perfect excision of some *Saccharomyces cerevisiae* introns (presumably by gene conversions by a complementary DNA copy of the spliced mRNA), and the existence of a mitochondrial plasmid in *Podospora anserina* that is identical to one of the four introns they present. These arguments are persuasive but not conclusive.

If the authors are correct, these are the first identified reverse transcriptase genes of cellular rather than viral origin. It has been proposed that retroviruses evolved from mobile DNA elements that picked up an ancestral reverse transcriptase gene while wandering around the genome^{24,25}. A cornerstone of this theory is the cellular reverse transcriptase gene, which has been conspicuous by its absence from the literature till now. Perhaps some maturases are the progenitors of modern reverse transcriptases.

Are all introns explicable as mobile, self-splicing elements? Probably not; the class I and II introns are rare except in fungal mitochondria, an exception being the *Tetrahymena* 26S rRNA intron. Other introns fall into two classes, the nuclear mRNA introns and the transfer RNA introns. Neither of these possesses genes that affect their transposition, although it is always possible to invoke a small number of yet uncloned trans-acting genes. Both classes furthermore are excised by mechanisms very different from the class I and II introns, although mRNA splicing does create circular lariat intron excision intermediates that are reminiscent of the perfect circles created from class I/II excised introns^{3,4}. Nevertheless, the possibility that introns are relics of ancient mobile elements must still be considered. By this hypothesis the large majority of introns have long since evolved away from a migrating lifestyle.

Another possibility is that the class II maturase-containing introns are the descendants of the fortuitous incorporation of a reverse transcriptase gene by genomic rearrangement. The resulting construct

* I am grateful to Donal Hickey for communicating to me his ideas on intron evolution, in particular the possibility that introns are descendants of highly specialized retrotransposons. This will in part be presented as a letter in *Scientific Correspondence*.

would be able to ensure its survival by replicative transposition. This seems a more likely possibility: we know of many examples of DNA rearrangements and the success of mobile elements in eukaryotic genomes is similarly obvious. Of course, if the incorporated reverse transcriptase gene came from a retrovirus we are back at square one in our search for the ancestral gene.

How might an intron transpose using reverse transcriptase? For the intron to survive more than one cycle of retrotransposition, the ends of the element would have to correspond exactly to the region spliced out of the pre-mRNA (this is especially important for intron insertion in open reading frames). The splicing signals would need to be contained in the intron; this is the case for class I/II introns. The most attractive model employs the circular RNA molecules generated from introns after excision. It is easy to imagine reverse transcriptase converting these into a double-stranded DNA circle that would presumably be cleaved where the ends of the intron meet, and inserted into the acceptor site. One problem with this model is that the circles lose a few nucleotides from their 5' ends during circularization²⁶, and these would need to be restored upon integration to preserve the intron intact. One attraction of this model is that DNA circles are used in retrovirus proviral integration, thus to some extent unifying the two mechanisms.

Is there any evolutionary evidence for intron insertion in characterized gene families? The mammalian serine proteases have been thoroughly studied in this respect²⁷. There is strong circumstantial evidence supporting the insertion of introns into the chymotrypsin, elastase, urokinase and human tissue plasminogen activator genes. But these are nuclear mRNA introns and the reservations mentioned that these are potential mobile self-splicing elements must be considered.

One well-characterized example of in-

tron insertion occurs in yeast mitochondria. The class I r1 intron of the 21S rRNA gene of *S. cerevisiae* mitochondria is optional²⁸ and several other yeast mitochondrial introns are similarly heterogeneous. As alleles containing the r1 intron (ω^+ alleles) yield almost entirely ω^+ progeny when crossed with ω^- stocks, the intron seems to invade the ω^- 21S gene²⁹. The mechanism is thought to be a specialized form of gene conversion, with similarities to the yeast mating-type cassette switching at the *MAT* locus. Evidence for this comes from co-conversion of flanking genetic markers during $\omega^- \rightarrow \omega^+$ conversion and the presence of a double-stranded DNA break at the recipient site that is highly reminiscent of the y-z endo cut at the *MAT* locus³⁰. The exciting aspect of this mechanism is that the open reading

frame of the r1 intron is required for this process^{14,15}, showing that the intron encodes a gene product that catalyses its transposition. The r1 open reading frame shares homology with the maturase of the b2 intron of the yeast mitochondrial *cob* gene but not with the class II reverse transcriptase-related introns of Michel and Lang. However, unlike b2, the r1 gene product is not necessary for the splicing out of its own intron.

The connection between either the r1 type of intron or the class II intron of Michel and Lang and the maturase function is still unclear. Further study will not only clarify this issue but may tell us much about intron evolution. □

Polymer biochemistry

Radical breakdown of lignin

from Alistair Paterson and Knut Lundquist

ALTHOUGH certain fungi have no problem in degrading lignin, one of the major constituents of wood, biochemists have had a problem in explaining the mechanism by which a polymer with so many different inter-monomeric linkages is degraded. Intensive research has culminated in the discovery that the mechanism involves an enzymatic one-electron oxidation of lignin yielding aromatic radical cations that initiate cleavage of the side chains¹⁻³.

Lignin is synthesized by the addition of phenoxyl radicals, generated by dehydrogenation of the precursor *p*-hydroxycinnamyl alcohols, to the growing polymer chain. Most of the links in the resulting polymer are ether bonds between the central propanoid carbon (C β) of one monomer and the phenolic group of the next, referred to as β -aryl ether linkages, although nearly a dozen other bonds of carbon-carbon and ether type have been reported, giving lignin an irregular structure.

The most effective degraders of lignin are the white-rot fungi, of which the basidiomycete *Phanerochaete chrysosporium* is the best characterized. When growing in mycelial form in static liquid and solid culture, nutrient exhaustion initiates secondary metabolic or idiophasic activities in this fungus. At that time, it begins

to secrete small quantities of 'ligninase', a glycosylated haemoprotein, and to decompose lignin into CO₂. The ligninase was first described in 1983 by Ming Tien and T. Kent Kirk⁴ at the US Department of Agriculture Forest Products Laboratory in Madison, Wisconsin and by Michael Gold's group at Oregon Graduate Centre, Beaverton⁵. Initially, it was reported to require both hydrogen peroxide and molecular oxygen for activity and to degrade both a range of lignin model compounds and extracted native lignin.

The precise mechanism of ligninase activity has since been under detailed study, though limited by the small quantities of purified enzyme available. Now, Kirk and his group¹ and John Palmer and colleagues at Imperial College, London^{2,3} have shown that the initial reaction in the attack on lignin models is a one-electron oxidation that generates relatively stable aromatic radical cations in the lignin polymer. The haem-containing ligninase first reacts with hydrogen peroxide, producing a change in the ultraviolet absorption spectrum of the enzyme akin to that when an oxy-ferryl complex is formed in peroxidases. The enzyme is then able to oxidize lignin models in the presence or absence of oxygen; electron spin resonance studies of the oxidation of dimethoxybenzenes¹ and veratryl alcohol by ligninase yield spectra with signals that are consistent with the generation of the aromatic radicals.

This oxidation can be mimicked by either of two metal-centred oxidant and dimeric lignin model substrates containing an aryl ether linkage. One is tetraphenylporphyrinatoiron(III) in the presence of *tert*-butylhydroperoxide⁶, which is thought to model the oxy-ferryl complex of the monooxygenase cytochrome P-450

Suggested route of lignin depolymerization for a model compound of the β -aryl ether type.

and peroxidases; the other is tris (phenanthroline) iron(III)³. The results suggest that the central feature of the 'ligninase' mechanism is the creation of the oxyferryl centre of high redox potential. Study of enzymatic attack on the lignin model substrate shows that a radical cation is formed by removal of an electron from the aromatic ring. The model compound then undergoes α - β alkyl cleavage with formation of a benzaldehyde and a radical, as shown in the figure. The latter can react with molecular oxygen, explaining the oxygen-18 labelled products observed in earlier reports.

Ligninase is clearly distinct from the metalloenzymes laccase and peroxidase, whose activity towards lignin model compounds has been thoroughly studied. Laccase is a copper-containing phenol oxidase that is produced by ligninolytic fungi but is also involved in the morphogenesis of non-ligninolytic basidiomycetes. This enzyme oxidizes substrates containing free phenolic hydroxyl groups, whereas ligninase is capable of oxidizing substrates with alkoxyl substituents on the ring; in the lignin polymer most of what were phenolic hydroxyls have been converted to the structural ether linkages. The oxidative changes in phenolic substrates — catalysed by ligninase or laccase — differ considerably from those produced in non-phenolic substrates by ligninase^{7,8}.

For some time, experimental evidence suggested that hydroxyl radicals, which are non-specific oxidants, mediate fungal degradation of lignin. But when Fenton's reagent, which chemically generates such radical species, is used to degrade lignin model compounds, the products differ from those of the enzymatic oxidation⁹. The specificity of the enzymatic reaction can be explained if its postulated oxyferryl centre has a lower redox potential than the hydroxyl radical but a higher potential than other peroxidases.

Once generated by the ligninase, the radical cations are themselves able to act as one-electron oxidants which can oxidize sites remote from the enzyme. Thus, despite the attention still being paid to extracellular proteins from ligninolytic *Phanerochaete chrysosporium*, there would seem to be no reason why ligninase (which is capable of cleaving many of the lignin intermonomeric linkages¹⁰) and laccase, together with the organism's oxidative cellulases (which have roles in reducing quinones¹¹, produced by oxidative lignin degradation and in generating the hydrogen peroxide¹² that is required to form the oxyferryl centres)

should not be able to catalyse all the lignin depolymerizations that have been observed up to now. □

Astrophysics

New detectors for gravity waves

from James Hough

DIRECT detection of gravitational radiation remains one of the most challenging and difficult problems in experimental physics. Success in this field will be of considerable significance both for astronomy where new information about violent interactions in the universe may be obtained, and for physics where fundamental aspects of relativity theories may be checked. Indirect evidence for the existence of gravitational radiation has been provided by observations on the binary pulsar PSR 1913+16 and this provides added encouragement for the development of experiments in the field.

The detection of gravitational radiation relies on sensing the fractional strain or amplitude in space induced by the wave, through the effect on test masses, which may be essentially free or which may be coupled together mechanically. The resulting effective displacements of the test masses increase with their distance apart. Alternatively, the effect of the radiation on the phase of electromagnetic waves may be used. Radiation from possible sources ranges in frequency from 10^{-4} Hz for large black hole interactions and 10^{-3} Hz for fast binary stars to 10^3 Hz for stellar collapses (see table). To some extent the

frequency being searched determines the choice of detection method.

Detectors based on Earth look very promising for frequencies above several tens of Hertz, but are limited at low frequencies by the effects of seismic and man-made noise. At very low frequencies, one cycle per year or lower, pulsar timing is providing interesting limits on the gravitational wave background^{1,2}. In this case the pulsar is acting as a very stable clock, and the effect of gravitational radiation on the phase of its radio signals is being sought. A stable clock on Earth that forms the bases of a spacecraft tracking system can be used for higher frequencies, and Doppler tracking of interplanetary spacecraft has already allowed searches in the millihertz range to be made at a gravitational-wave amplitude level of roughly 3×10^{-14} (ref. 3). The performance is limited by plasma scintillation affecting the radio signals. The significance of this may be reduced in future by using dual tracking frequencies, but better performance could be obtained by using optical frequency tracking. To avoid the effect of the Earth's atmosphere, however, the whole system would then need to be spaceborne.

In the long-term, the performance of

Some possible sources of gravitational radiation

Impulsive sources				
	Amplitude	Predominant frequencies	Rate	Detection method
Black hole events in galactic nuclei and quasars	$\sim 10^{-19} - 10^{-16}$	$10^{-1} - 10^{-4}$ Hz	< 50 per year	Doppler tracking initially then laser interferometer in space
Stellar collapse (at distance of Virgo Cluster)	$\sim 10^{-22} - 10^{-21}$	< 10^3 Hz	~ 1 per month	Cooled bar detectors, laser interferometers on Earth
Neutron star binary decay (out to 100 MPC, for example)	$\sim 10^{-22} - 10^{-21}$	$\sim 10 - 10^3$ Hz	$\sim$ few per year	Laser interferometers on Earth
Continuous sources				
	Frequency	Amplitude	Detection method (with integration for $\sim 10^6 - 10^7$ s)	
Pulsars				
For example, the Crab Nebula	60 Hz	< 10^{-25}	Laser interferometers on Earth	
Binary stars				
Iota Bootes	8.6×10^{-5} Hz	$\sim 5 \times 10^{-21}$	Laser interferometer in space	
Am CVn	2×10^{-3} Hz	$\sim 10^{-21}$	Laser interferometer in space	
Gemina ⁵	3×10^{-2} Hz	$\sim 10^{-19}$	Laser interferometer in space; 'Skyhook' detector	

Alistair Paterson is moving from the Department of Biochemistry and Applied Molecular Biology, UMIST, Manchester to the Department of Bioscience and Biotechnology, Food Science Division, University of Strathclyde, Glasgow G1 1SD, Scotland; Knut Lundquist is in the Department of Organic Chemistry, Chalmers University of Technology, S-412 96 Göteborg, Sweden.

laser interferometry between test masses in satellites spaced a million kilometres or more apart looks very promising, with a potential sensitivity⁴ of about 10^{-21} at frequencies below 10^{-1} Hz. In the shorter term, Braginsky and Thorne⁵ propose an interesting detector of intermediate sensitivity (see page 610 of this issue). Their proposed 'skyhook' detector would consist of two masses on each end of a long thin cable with a spring at the centre, the whole system being arranged to orbit the Earth. By sensing the motion of the test masses as transmitted to the spring, a search for gravitational waves could be carried out with an amplitude sensitivity of 3×10^{-17} at frequencies of 10^{-1} – 10^{-2} Hz. This is clearly an experiment to be considered in the near future as it could be ideal for searching for the radiation from a black hole-white dwarf binary system, such as Geminga may be, from which an amplitude signal of approximately 10^{-19} at the Earth at approximately 3×10^{-2} Hz has recently been predicted⁶. Integration of the signal over several months could allow successful detection.

While space experiments are exciting for the future, the potential of ground-based experiments operating over a frequency range from several-tens of Hertz to a few kilohertz seems considerable. These experiments are aimed at the detection of gravitational waves from sources such as stellar collapses, coalescing binary stars and fast pulsars. Astrophysical models are somewhat uncertain, but theoretical predictions suggest that a strain sensitivity of 10^{-21} – 10^{-22} over a kilohertz bandwidth should be adequate for the detection of fast-pulsed sources, and 10^{-27} over a narrow bandwidth would be an interesting level for pulsars.

Current experiments use two main approaches. One, the development of the Weber bar detectors using low temperature techniques to reduce thermal noise, is under investigation at a number of places including Stanford University, the University of Louisiana, the University of Western Australia, and at CERN where the University of Rome are mounting a significant effort. The Stanford detector is already achieving a strain sensitivity of approximately 10^{-18} for millisecond pulses with plans to improve this sensitivity by two orders of magnitude over the next five years, and to design a detector system to cover a wide frequency band (a fuller discussion can be found in ref. 7).

The other approach is to increase the signal size by using freely suspended test masses placed a long distance apart. Such an arrangement is inherently wideband. To avoid absolute length measurements, the test masses can be suspended to give two perpendicular baselines in which the gravitational wave signal will induce a differential displacement. The relative length of the two arms can be monitored by laser interferometry, and the optical phase changes can be enhanced by reflect-

ing the light back and forward between a system of mirrors on the test masses, which may form an optical delay line⁸ or resonant Fabry-Perot cavity⁹. A number of prototypes of such detectors are under development. Two of these use optical delay lines (at the Max Planck Institute, Garching, where the arm length is 30 m, and at the Massachusetts Institute of Technology with an arm length of 1 m), and two use Fabry-Perot cavities (University of Glasgow and California Institute of Technology with arm lengths of 10 m and 40 m respectively).

The performance of these prototype detectors is encouraging: strain sensitivity spectral densities of better than 5×10^{-19} Hz^{-1/2} have been achieved by those with longer baselines. And it is generally agreed that they have reached a stage where the construction of detectors with much longer baselines should be considered. The optimum arm length for a detector of this type is a compromise between possible sensitivity, range and flexibility of experiments, and the relative importance of anticipated noise sources. The availability of large areas of flat land and the cost and timescale of building the apparatus also influences the choice. At present it seems that the optimum arm length is a few kilometres. A detector with its masses fitted with mirrors of very low loss, as have been developed for laser gyroscopes, and illuminated by several tens of watts of continuous laser light from an array of high power argon lasers (or a YAG laser), could achieve a sensitivity of close to 10^{-22} for millisecond pulses of gravitational

waves and equally encouraging sensitivity figures for other types of sources.

To set up a useful 'telescope' array on Earth, it would be best to have at least four such detectors. Currently there are plans to have two in the United States developed from the Caltech and MIT prototypes, one in Germany as an extension of the current Max Planck experiments, and one in Scotland as a development of the work at the University of Glasgow. In addition, there is a possibility of a fifth instrument being built in France. If the construction of these detectors proceeds there is a very real chance that gravitational radiation from astrophysical objects will be directly detected within a decade. Towards the end of this time certain of the spaceborne experiments could be giving results in the low frequency part of the spectrum. Evaluation of results from the experiments on Earth and in space can be expected to herald a new and very exciting era for astronomy. □

Population dynamics

Water fleas as population model

from John H. Lawton

THE most widely used and familiar equation in population dynamics is the logistic¹. It is also the most boring, permitting as it does just one sort of dynamic behaviour — sigmoid growth to a stable equilibrium from low population numbers and monotonic decline to the same equilibrium from above. Many real populations do more interesting things, as Murdoch and McCauley², using *Daphnia* (water flea) population dynamics, demonstrate on page 628 of this issue.

Some of the complexities of real population dynamics can be mimicked by modifying the logistic to incorporate a time-lag in the density-dependent term¹.

$$dN/dt = rN[1 - N(t-T)/K] \quad (1)$$

Where N is population density at time t , r is population rate of increase, K is the equilibrium population size, and T is a time-lag in the response of the population to density. When $T=0$ we recover the logistic. With $T>0$ the modified model generates a range of behaviour¹ including sigmoid growth (for $0 < rT < e^{-1}$) or

damped oscillations ($e^{-1} < rT < \pi/2$) to a stable equilibrium K set by food supply or space; alternatively, stable-limit cycles are generated when $rT > \pi/2$. Density-independent disturbances cause non-cyclic fluctuations round the stable equilibrium, and may sufficiently perturb the damped oscillations to yield 'quasi-cycles'³ — fuzzy, but regular, oscillations.

These more complex behaviours recall those discussed by Murdoch and McCauley². Indeed equation (1) has been invoked to explain the wide range of dynamic behaviour shown by laboratory populations of both *Daphnia* and planktonic rotifers, by postulating changes in the relative values of r and T under different temperature regimes^{1,4} (see figure). To date, analogous ranges of behaviour for field populations have been sought among many biologically disparate taxa and food webs (for example ref. 5). But they have not been demonstrated in the field for one species or closely related set of species under structurally similar conditions —

that is, when essential links in the web of community interactions between prey, predators and competitors remain unchanged. Yet the model explicitly predicts different dynamic behaviour under structurally identical conditions, providing only that key parameter values change in relative magnitude.

Time-lags are inevitable in many population interactions involving real organisms. For example, it takes at least a gestation period for animals to respond to increasing food supplies. But although equation (1) crudely incorporates time-lags, it is still a gross simplification of reality. A step nearer to the truth is a pair of equations — one for the consumer pop-

Laboratory populations of (a) the rotifer *Brachionus calyciflorus* and (b) *Daphnia magna* under different temperature regimes but otherwise identical culture conditions. Increasing temperatures change the dynamic behaviour from approximately sigmoid growth or damped oscillations to regular cycles (a modified from ref. 4; b after D.M. Pratt in ref. 10).

ulation (herbivores) and one for the food (green plants), that is, equations in the form of a Lotka-Volterra 'predator-prey' model⁶. Appropriate choice of parameters in such a model again generates the full range of behaviours shown by equation (1) in both prey and predator populations.

Not unreasonably, many field biologists remain sceptical or even hostile^{7,8} to such simple models. They may, after all, appear to do all the right things for entirely the wrong reasons. Therefore, the models need testing. The first step is to find a set of field populations that do some, if not all of the 'right' things. As Murdoch and McCauley show, *Daphnia* and their algal prey seem to be ideal subjects to test the pair of equations, providing that obvious pitfalls, such as fish predation, are avoided. What we then seem to have is the two-species field equivalent of a Lotka-Volterra predator-prey model.

Murdoch and McCauley's *Daphnia*-

algal data challenge the theoretical models in at least three ways. First, and most crudely, do both the relative values of time-lags in the system and *Daphnia* rates of increase agree with the simple predictions of equation (1) for the three classes of populations recognized by Murdoch and McCauley. These are stable (class 1) and cyclic (class 2 and 3) *Daphnia* populations? Second, is it possible to obtain estimates for the parameters of two-species Lotka-Volterra equations, and thus test this more realistic model? For example, is stability (class 1) imposed by mutual interference (intraspecific competition) amongst the *Daphnia*, or by low grazing rates⁶; and do populations in class 2 show quasi- or stable-limit cycles under conditions predicted by the models? Third, as Murdoch and McCauley point out, how is it that class 3 *Daphnia* populations cycle, but not their algal prey? This particular behaviour is not predicted by Lotka-Volterra equations, so either the model or the data are misleading.

It is not difficult to imagine many complexities hidden in these data that may invalidate detailed comparisons with simple models. Examples range from competition between algal species (or between *Daphnia* and other zooplankton), to unsuspected invertebrate predation on *Daphnia* by *Chaoborus* (phantom midges), *Leptodora* (predatory relatives

of *Daphnia*) or water mites, to algal parasites⁹. Indeed, it is extremely unlikely that in the long run, simple Lotka-Volterra models will prove sufficient to model all the complexities of *Daphnia*-algal populations. That is not the function of simple models. Rather, they serve to chart a difficult course between gross simplicity (the logistic) and too much complexity (the field). The models highlight processes that seem fundamental to the dynamics, and signpost the next round of field observations and experiments. In short, *Daphnia* and algae present ecologists with an opportunity to test some important, general, widely used but often maligned models, but at the same time, keeping both feet firmly planted in the muddy complexities of the nearest pond. □

Glaciology

Contrasts in Vostok core — changes in climate or ice volume?

from G. de Q. Robin

CORES from the major ice sheets provide fossil samples of the Earth's atmosphere and yield information on past climates and the mechanisms of glaciation. But obtaining such cores has never been easy, and a really long record has proved elusive. Now Soviet engineers have drilled an ice core of high quality to 2,083-m depth at Vostok station at 78°S, the coldest inhabited place on Earth. This core from East Antarctica is the first to span the last interglacial and recover ice from the preceding glacial period. Papers on p. 591 and 616 of this issue provide an exciting glimpse of results to come from geochemical studies of this 150,000-year climatic record^{1,2}.

Dating of the ice core is based on my observation that current accumulation rates in central Antarctica vary with mean atmospheric temperature above the ground inversion³. These temperatures are reflected in the $\delta^{18}\text{O}$ profile determined by Lorius *et al.*¹ and are used by these authors to extrapolate from present to past accumulation rates. The agreement of the resultant date for the last interglacial with that obtained by other methods suggests the method is satisfactory, as

does the agreement with accumulation rates deduced from the ^{10}Be studies of Yiou *et al.*² Some corrections to allow for increased atmospheric transport of dust⁴ and thus of water vapour during the last glacial maximum may be desirable. The new method is an improvement on dating of marine sediment cores, where uniform accumulation rates between horizons marking prominent climatic boundaries 20 – 60 kyr apart are usually assumed.

Since the annual accumulation around Vostok is less than the surface roughness due to sastrugi (irregularities caused by the scouring action of windborne ice particles), deposition noise levels⁵ in the $\delta^{18}\text{O}$ record are high. The sampling length of 1.5 – 2 m (equivalent to 100 – 200 years) reduces this noise to around $\pm 0.5^\circ$ per thousand (standard deviation). This is similar to deposition noise levels found by comparing measurements from 20 shallow bore holes 600 km away at Dome C station⁶. Separate measurements at 25-m intervals along the whole core (Fig. 1 in Ref. 1) lie mostly within two standard deviations of the continuous curve below 1,406 m, although a difference of four

Suggested zones where the Antarctic ice sheet was thicker or thinner (that is, the ice surface was higher or lower) during the last glacial maximum than at present⁸. This is compared with corresponding surface elevation estimates from Denton & Hughes¹⁶. Thicker ice in coastal regions is due to increased grounding of ice as sea level falls during an ice age. Lower ice surfaces inland show responses to lower accumulation rates suggesting that surface levels of ice streams and glaciers discharging ice from central regions undergo little change or even fall slightly¹⁰.

standard deviations occurs at the interglacial maximum. Within these limits, most fluctuations in the $\delta^{18}\text{O}$ profile can be related to global climatic factors⁷. A notable exception is isotope Stage F; the Vostok record shows much colder conditions than do other marine, ice and terrestrial data for that time.

A rough periodicity of around 40 kyr in the $\delta^{18}\text{O}$ profile, in phase with summer insolation changes at 80°S, strongly suggests a connection with the 'Milankovitch' orbital variations. Together with the similarity in isotope composition at the four minima recorded, this led Lorius *et al.*¹ to conclude that the $\delta^{18}\text{O}$ profile at Vostok primarily records climatic (regional temperature) changes and that effects of changes in surface elevation are small. This relative emphasis on a regional rather than a global explanation of the Vostok climatic record is due in part to the difficulty of finding a satisfactory mechanism of heat transfer between the hemispheres. However, probable changes in the latitude of the effective meteorological equator, in response to changes of radiation balance over the Earth's surface during ice ages, provide an equivalent mechanism (Radok, U. & Riehl, H. personal communication). A global response therefore remains plausible.

The alternative possibility, that ice surface levels over central Antarctica were lower (perhaps by 200–300 m), is supported by recent studies⁸ of factors affecting mean sea level — which may have been 5–7 m higher during the last interglacial. Applying the statement that "climate during the last interglacial was extremely similar to the present" (ref. 9) to the Vostok isotope profile leads to a similar conclusion. The difference between present day and interglacial $\delta^{18}\text{O}$ values could then be interpreted as indicating that the surface elevation around Vostok was about 300–350 m lower during the interglacial than now. If extrapolated to most of central Antarctica, the reduced volume of water bound up in the Antarctic ice sheet would be sufficient to explain the higher sea level, even though the climate

and glacier volumes other than in central Antarctica were the same. This hypothesis avoids the difficulty either of having to melt large sections of the Greenland and Antarctica ice sheets or of having the West Antarctic ice sheet collapse with little change of climate, in order to provide the necessary water. The higher sea level at this time also need not be interpreted as an indication of higher temperature⁹.

Evidence from several sources⁸, including Lorius *et al.*⁴ and Drewry¹⁰, suggests that surface levels in central Antarctica were somewhat lower during the last glacial period than at present (see figure). Because the accumulation rate is very low, the response time of ice thickness to climatic change in central Antarctica is probably tens of millennia compared to a few millennia in coastal regions. Consequently the ice thickness at the start of an interglacial will reflect conditions during the previous glacial period. Marine cores and terrestrial evidence indicate the glaciation from around 200–135 kyr was both colder^{11,12} and the colder temperatures were more prolonged¹¹ than that preceding the present interglacial. Hence average surface elevations in central Antarctica could have been 200–300 m lower around 135 kyr BP than during the Holocene. Applying a similar argument to isotope Stage F suggests that ice then may have been up to 200 m higher than at present following an interglacial buildup. Regional climate would then be some two degrees warmer than that deduced from the assumption of constant elevation in central Antarctica. This would reconcile the Vostok $\delta^{18}\text{O}$ values with general climatic records.

A problem with the surface elevation changes suggested above is that they are larger than expected from steady state glaciological theory. This could be explained by combining aerial and temporal variations of ice accumulation rate in Antarctica. Data from Lorius *et al.*¹ suggest an approximate ratio of 100:60 between interglacial and glacial accumulation rates in central Antarctica. This is supported by the findings of Yiou *et al.*² on precipitation rates. With present day accumulation

rates of 2.5 cm of ice per year at 3,500-m elevation around Vostok and around 10 cm of ice per year at about 2,500 m, the corresponding rates during a glacial period would be 1.5 and 6 cm per year respectively. During an interglacial period of say 20,000 years, 200 m more ice would accumulate at Vostok than during an equal time in a glacial period. At 2,500-m elevation the difference could be as much as 800 m. This would reduce an initial 1,000-m elevation difference between two sites to 400 m after 20,000 years of interglacial conditions, if ice flow were unchanged. Since flow is driven by a shear stress proportional to the product of ice thickness and slope, the dominant influence will not be the increased ice thickness but the decreased surface slope. This will decrease flow once an interglacial period starts and will further increase ice thickness. Such feedback could help explain the rather large elevation changes that it is possible to deduce from the isotope date. It could also explain the present relatively low surface slopes on central Antarctica, which have been cited as evidence of a former surge of the ice sheet¹³. The small positive mass balance in the Antarctic ice budget, noted recently¹⁴, would also be consistent with central elevations that are increasing slowly.

The question of whether the results from Vostok should be explained mainly in terms of climatic effects on an ice sheet of constant surface elevation or by ice volume changes in central Antarctica may be resolved¹⁵ when more detailed isotope and total gas volume measurements become available. Whatever the answer, the Vostok core will have been of considerable importance in unravelling the history of the past global climate, ice volume and ocean levels over a full glacial cycle. □

Gene control

False starts in translational control of gene expression

from Tim Hunt

THE control of eukaryotic gene expression at the stage of translation of messenger RNA into protein has always been a theoretical possibility, but surprisingly few clear examples have been identified. And even in the well-studied cases, detailed molecular explanations are almost wholly lacking. However, a number of cases of selective translation of mRNA are known and interesting clues to the mechanisms that underlie this kind of regulation are beginning to emerge from recent studies.

These studies focus attention on a number of unanswered questions about how the translational machinery operates. For example, it is known that translation is initiated at an AUG codon in the mRNA; but if there is more than one AUG, how does the ribosome know which to use? What determines the frequency with which a particular message is read? When a ribosome has finished translating an open reading frame in a message, can it start up again if a suitable AUG follows in that same mRNA? Can cells keep a mRNA altogether untranslated in some circumstances, but translate it if the circumstances change? All these questions are yielding interesting new answers, thanks mainly to nucleotide sequence analysis of natural mRNAs and the ability to test hypotheses by making alterations to these mRNAs or by constructing synthetic messages using recombinant DNA methods.

Scanning

According to the 'scanning' hypothesis formulated by Marilyn Kozak¹, the eukaryotic ribosome moves down the mRNA from the 5' or upstream end (which is usually capped) until it encounters the first AUG codon, whereupon translation is initiated. In more detail, 40S ribosomal subunits bearing Met-tRNA_i move along the mRNA until the anticodon of the Met-tRNA_i engages with the first AUG, whereupon the 60S ribosomal subunit joins on, the next tRNA is inserted and the first peptide bond forms. Then the (now) 80S ribosome moves down the mRNA, translating it into protein until a termination codon is reached. This causes the protein to be released from the ribosome, and the ribosome to leave the mRNA, presumably by reversing the initiation process and dissociating into its subunits. These processes, which are not very well understood, may in the light of recent findings, prove to be important in the translational control of protein synthesis: for it turns out that the coding

regions of certain mRNAs are preceded by up to four starts and stops.

As the Kozak model predicts, the first AUG is used in over 90 per cent of mRNAs whose sequences are known. It usually occurs between 50 and 100 residues from the 5' end of the message, often as the consensus sequence PuN-NAUGG. However, in about 5 per cent of cases, one or more AUGs occur upstream of that which leads to synthesis of the supposed product of the message. What happens when ribosomes encounter these false starts? And, if they are read, what are the consequences?

These questions have been answered in part by deliberately inserting AUGs upstream of the 'real' AUG in mRNAs². In general, it seems that an inserted AUG preempts the natural one, in accord with the scanning hypothesis. If the reading frame of the false start is the same as that

within the first 200 residues of a 2,000 nucleotide mRNA, two AUGs give rise to different proteins formed by alternative starts in the same reading frame, while third protein of completely different length and sequence derives from a AUG in a different reading frame³. A rather similar situation occurs in adenovirus, where an mRNA from the *E1b* gene specifies alternative proteins according to which AUG is used⁴; the first occurs very close to the 5' end of the message and is often ignored in living cells, but it seems to be preferred in cell-free translation systems. These cases do not strictly qualify as examples of translational control, because there is no evidence that the frequency of initiation from the alternative AUGs can be regulated. Rather, they seem to represent cases of economical use of the viral genome, made possible by exploiting wrinkles in Kozak's rules.

Translational control

By contrast, it is now known that expression of the yeast *GCN4* gene (involved in the General Control of Nitrogen metabolism) is regulated primarily at the level of translation^{5,6}. The *GCN4*-encoded protein is a positive transcriptional regulator of many genes involved in amino-acid

of the real one, the result is an amino-terminally extended protein (compare Fig. 1a with 1b). But if, irrespective of the frame of the upstream AUG, termination signals (the codons UAG, UAA or UGA) occur between the false and real starts, ribosomes resume reading the real message, suggesting that they remain attached to the mRNA after terminating synthesis of the first protein, and are able to start up again if a suitable AUG presents itself within a reasonable (but undetermined) distance (see Fig. 1c).

While these experiments support Kozak's rule, there are several cases of different natural AUGs in the same mRNA being read to give alternative products. This suggests that ribosomes can miss an AUG, perhaps if it is embedded in a sequence that is poorly matched to Kozak's consensus sequence.

The mRNA coding for the P and C proteins of Sendai virus is a good example;

biosynthesis. Its synthesis is boosted something like 100-fold when yeast is starved of any essential amino acid. Its level of expression depends on the activity of a repressor specified by the *GCL* locus, whose activity is in turn somewhat regulated by the *GCN1*, 2 and 3 loci. Until recently it was assumed that this complex regulatory hierarchy operated at the stage of transcription, but it now emerges that the level of *GCN4* mRNA stays essentially constant regardless of the nutritional state of the cell: what changes is the rate at which it is translated. Clues to the mechanism are evident in the structure of the mRNA. It has a 5'-untranslated sequence which, at 5' nucleotides, is much larger than normal and there are four AUG codons upstream of the 'real' one, each followed by a termination codon two or three codons later. A deletion of 280 nucleotides that removes all the upstream AUGs leads to greatly increased translation of the message, consid-

tent with the idea that the upstream AUGs limit translation in some way. Experiments in which point mutations are made in the AUG codons are under way; until the results of these emerge, it will not be clear whether the upstream AUGs are actually read by ribosomes. But, assuming this is the mechanism, how is it triggered by amino-acid starvation?

Amino acid starvation is almost certainly sensed by ribosomes themselves. In bacteria, ribosomes that get stalled on mRNA waiting for a missing aminoacyl-tRNA convert a very significant fraction of intracellular GTP into pppGp and pppGpp. These compounds reach high levels and activate the 'stringent response'. No analogous conversion of low molecular weight phosphorylated compounds has ever been detected in eukaryotic cells despite many searches, so something different must be going on in yeast. The other bacterial paradigm, 'attenuation', acts at the level of transcription and is clearly not directly applicable. Besides, there does not seem to be any correspondence between the amino acids specified by the tiny reading frames following the upstream AUGs and those whose depletion turns on the *GCN4* gene product synthesis. Thus we must await further elucidation of the molecular modes of action of the *GCD1* and the other *GCN* gene products before understanding much more. Probably they are closely involved in the protein synthesis machinery, a hypothesis strengthened by the inviability of *GCD1* mutants.

A strong echo of this story returns in the report of the surprising sequence of a full-length cDNA clone corresponding to ornithine decarboxylase, an enzyme that is involved in polyamine biosynthesis and is extremely rapidly produced by cells that have been stimulated by hormones and growth factors. The interesting thing about its mRNA is that it contains a 737-nucleotide 5'-untranslated region containing four AUG codons upstream of the long open reading frame, followed by terminators 16, 2, 4, and 10 codons later. In broad outline this is highly reminiscent of *GCN4* mRNA (see Fig. 2). The mRNA for ornithine decarboxylase is not very efficiently translated *in vitro*, suggesting that ribosomes rarely reach the proper coding region, but it is not known whether its translational efficiency changes with the physiological state of the cell; if so, does the long leader plays a part in the regulation? It would be very interesting to put this mRNA into yeast and see if amino-acid starvation made any difference to its expression.

There are still relatively few cases in which specific translational control has been shown to occur in eukaryotes, which is one reason the *GCN4* example is so exciting. Several well-known examples, such as the displacement of normal cellular mRNA and the induction of new protein synthesis after heat-shock, or virus-

induced shut-off of host protein synthesis, remain poorly understood at the molecular level. There are several examples of 'masked' mRNA in eggs and oocytes — that is, messages that are very abundant but essentially untranslated until after fertilization. The mRNA that encodes the small subunit of ribonucleotide reductase in clam and sea urchin eggs is a very good example¹. We do not have the complete sequence of any of the mRNAs that show this behaviour, nor any other possible clues as to the mechanism involved. Another rather striking example of developmentally timed 'unmasking' of mRNA is provided by *Xenopus* fibronectin mRNA, present in unfertilized eggs but untranslated until about the time of the midblastula transition, 6–7 hours after fertilization². It would be well worth looking at the 5'-untranslated leader of this message to see if it gives any clues to the masking mechanism. A recent and particularly spectacular example of translational control is that in *Volvox*, where the pattern of protein synthesis changes dramatically in response to light³.

Pointers

Two other helpful points about 5'-untranslated regions have been discussed in recent publications. First, when RNA sequences capable of forming strong secondary structure (inverted repeats rich in GC base pairs) are engineered into the 5'-untranslated sequence of a mRNA, translation of the mRNA is reduced⁴. Second, annealing the untranslated sequence (including the initiation codon) with complementary DNA or RNA completely stops ribosomes finding the start of the mRNA, though once ribosomes start polymerizing amino acids, they are apparently able to unwind or peel off such double-stranded impediments to their progress^{5,6}. Control mechanisms could exploit these features; the 5'-untranslated region of mRNA is the first place to look for possible regulatory sequences.

But neither argument nor experiment has yet settled the role of long 5'-untranslated sequences, with or without upstream AUGs or secondary structure, in the regulation of translation of mRNA. It is certainly not the case that all mRNAs with long leaders are very inefficient; encephalomyocarditis viral RNA which has

an exceptionally long untranslated segment, which includes several upstream AUGs, is one of the most active messages known, both in reticulocyte lysates and infected cells. By way of contrast, the case of *c-myc* mRNA, which normally has a 5'-untranslated region of well over 400 nucleotides, seems to be controversial. It has been suggested that chromosomal rearrangements that cause shortening of this region result in increased expression of the protein by increasing the frequency of translation of the mRNA⁷, but two very similar experiments designed to test this directly (using synthetic mRNAs synthesized *in vitro* from cloned templates by SP6 RNA polymerase) have given conflicting results^{8,9}. An analysis of intact cells, which is anyway much more difficult, has not resolved the conflict¹⁰.

Thus, while it remains easy to imagine the existence of proteins that act as specific translational repressors and enhancers by binding to particular regions of the primary or secondary structure in the 5'-untranslated regions of mRNA, not one authentic example has yet emerged from years of studying mRNA and messenger ribonucleoprotein particles (excluding the poly(A)- and cap-binding proteins, which do not seem to play regulatory roles). I hope yeast will provide the real thing. □

Photosynthetically active radiation — a new unit

SIR—It is meaningful and useful, and now fashionable in studies involving photosynthesis, to express light intensities as micro-einsteins of photosynthetically active radiation per square metre per second: $\mu\text{E m}^{-2}\text{s}^{-1}$ (PAR). This unit is not a standard international one, as is a mole of photons. It could be confusing since to physicists the Einstein number is a velocity relative to that of light. In fact, it is obviously not a purely physical unit but a physico-botanical one, since spectra of photosynthetically active light differ among green plants, red and brown algae, diatoms, cyanophytes and other photosynthetic bacteria according to their respective complements of photosynthetic pigments: chlorophylls, bilin pigments, and so on. It is awkward to type, since it involves negative exponents and a Greek letter found on few typewriters. It is also a long phrase to use in common parlance, and referring to it briefly and colloquially as a "micro-einstein" is wrong.

I therefore suggest that for physico-botanical usage, in such fields as plant physiology, limnology and oceanography, we use a new nominal unit, the albert: 1 alb = $1 \mu\text{E m}^{-2}\text{s}^{-1}$ (PAR). (This continues to commemorate Albert Einstein.) It is a derived unit, like a joule or a roentgen. Very approximately, one kilo-lux is equivalent to about 20–40 alb, while full sunlight provides a light intensity in the range of 2,000–4,000 alb (depending on the latitude and on the kind of photosynthetic system involved).

Splicing and the evolution of introns

SIR—The recent suggestion by Cavalier-Smith¹ that introns have evolved by duplicative transposition within eukaryotic genomes is one which we believe deserves serious consideration. We would, however, like to offer an alternative to the model of transposition at the level of DNA. We propose that if introns are indeed the vestiges of transposable elements, they represent a class of retrovirus-like transposons or retrotransposons². The attraction of this latter model is that it gives the splicing mechanism a central role in the evolution of introns. There is a growing body of evidence to suggest that splicing is intron encoded^{3,4}. Consequently, it is reasonable to look for evolutionary explanations of the splicing mechanism in the context of the evolution of the introns themselves.

In our view, the ancestral intron genomes were replicated into RNA copies simply because of their insertion within

transcriptionally active regions of the host genome. Splicing was necessary not only to minimize negative effects on host gene expression⁵ but also, perhaps more importantly, to generate new copies of the intron genome free of flanking exon sequences⁶.

These spliced intron copies were then available for reverse transcription and reinsertion elsewhere in the genome. Most modern introns have probably lost much of their original genetic content and may be considered as degenerate evolutionary relics. An exception is the set of splicing signals which must be retained because of its importance to host cell survival.

Finally, we would like to point out that any particular model of the origin of introns does not argue for or against a subsequent short-term or long-term evolutionary role for these elements within the eukaryotic genome.

Current density and permittivity

SIR—John Maddox (*Nature* 316, 101; 1985), in his article on Maxwell's displacement current should have been more careful with his electrical units. J is not a current but a current density measured in A m^{-2} . The preferred name for ϵ is permittivity; it is not a scalar but in general a second rank tensor. The name dielectric constant for ϵ should be avoided, as ϵ usually varies with temperature and frequency and can vary with applied field strength. (See *Quantities, Units and Symbols*, Royal Society, London, 1975 and addenda 1981)

Null hypotheses and the misuse of statistics

SIR—Van Valen pleads for greater freedom for the applied scientist constrained by the "narrow Neyman-Pearson view of statistics as hypothesis-testing" (*Nature* 314, 230; 1985). He advocates a more flexible use of statistics and although in the main we do not disagree with this, our own experience in medical statistics leads us to believe the problem is more fundamental than misuse of null hypotheses.

Statistics involve three ingredients — technical statistics, language and method. Mastery of all three would be ideal. Mastery of technical aspects is a minimum

requirement, based on the organization of ideas according to established recipes defined by previously encountered 'typical research problems. The technical element then is more adapted to provoking action than to reflection, and if we agree that reflection followed by action underlies scientific progress, then we might reasonably consider it perverse for a researcher to be incapable of formulating hypotheses in the absence of stimuli from a computer.

The language of statistics is that of mathematical models and probability theory underlying the calculations. With the advent of computer packages and a much wider access to P -values, increasingly solicited by journals, mastery of the language is rapidly becoming seen as a specialist area only of use in unravelling the most complex situations.

Method is concerned with the fundamental approach and not immediate operational questions. Under this heading we have for example Bayesian techniques, parameter estimation and . . . hypothesis testing. The mistake is to regard these approaches as fundamental principles and to try and squeeze all problems under one or another heading. Worse still is to try and answer questions using one approach which can only be answered using another. To take epidemiology as an example, we almost have to admire the ingenuity whereby, to avoid modelling, problems are formulated in terms of the most untenable null hypotheses. Researchers aware of differential effects and yet with hopelessly inappropriate means for quantifying them find themselves writing $P < 0.0001$ to underline an effect of possibly greater importance than one for which, for instance, $P < 0.01$. Such an expression can find little motivation or meaning in the asymptotic framework of the distribution theory underlying any test, even when appropriate, and yet the optimistic expression $P < 10^{-7}$ is by no means unknown in the medical literature.

To would-be users of statistics it should be made clear that the acceptance or rejection of a null hypothesis does not establish scientific knowledge with the same degree of conviction and this is entirely consistent with Popper's outlook. Unfortunately we are tempted to overlook this fundamental logical asymmetry: thus while some will invoke a non-significant result as evidence for the equivalence of treatments others will invoke a non-significant result as proof of the comparability of patient groups before treatment. In contrast, a significant result will almost always be given a weight disproportionate to its scientific import, the constant of disproportionality varying inversely with the level of significance.

ANNOUNCING

MOLECULAR BRAIN RESEARCH

A section of Brain Research devoted to the publication of molecular studies.

CALL FOR PAPERS

Editor in chief.

D.P. Purpura,
Brain Research, Office of the Dean,
Albert Einstein College of Medicine,
1300 Morris Park Avenue, Bronx,
NY, U.S.A.

The powerful techniques and approaches of molecular biology have greatly enriched brain research in recent years. The wide application of recombinant DNA technology, monoclonal antibody production, molecular analysis of receptor-ligand interactions and ion channel mechanisms have generated a wealth of data bearing upon fundamental processes underlying the structure and function of nervous systems. Indeed it is anticipated that reports dealing with the application of molecular biological techniques will increase greatly over the next few years and require appropriate recognition and organization. Cognizant of the need to make such interpretations available to the

readership of **Brain Research**, we are pleased to announce publication of a new section of **Brain Research** entitled '**Molecular Brain Research**'. This decision carries with it awareness of the rapid progress in molecular biology of the nervous system as well as the desirability of encouraging the focus of molecular biological research on brain mechanisms. The Editorial Board of **Molecular Brain Research** will be announced at a later date. Prof. Dominick P. Purpura will serve as Editor-in-Chief of the new section.

Aims and Scope

Molecular Brain Research is a special section of Brain Research which provides a medium for the prompt publication of studies of molecular mechanisms of neuronal, synaptic and related processes, that underlie the structure and function of the brain. Emphasis is placed on the molecular biology of fundamental neural operations relevant to the integrative actions of nervous systems.

Principles of Neural Science Second Edition

Editors

Eric R. Kandel, M.D.

The Howard Hughes Medical Research
Center and Center for Neurobiology and
Behavior, College of Physicians and Sur-
geons, Columbia University.

James H. Schwartz, M.D., Ph.D.

The Howard Hughes Medical Research
Center and Center for Neurobiology and
Behavior, College of Physicians and Sur-
geons, Columbia University

The expanded, completely updated new edition of **Principles of Neural Science** will be available in the fall of 1985. Like its predecessor, this new edition applies the insights gained from current research in basic science to the study of the nervous system: its development, and its control of behavior. The second edition places an even stronger emphasis on cell and molecular biology and includes a new and systematic treatment of neuroanatomy as it relates to neurobiology and behavior, detailed enough to serve as a foundation for clinical neurology and psychiatry.

Principles of Neural Science, Second Edition, covers the extraordinary advances that are revolutionizing neuroscience research, including recombinant DNA and monoclonal antibody techniques, patch clamping, new neuroanatomical tracing methods, and new non-invasive methods of imaging.

Praise for the First Edition (Winner of the 1982 Medical Writers Book Award):

European Journal of Biochemistry

Published on behalf of the Federation of European Biochemical Societies (FEBS)
Managing Editors: C. Liébecq, Liège (Chairman); G. Bernardi, Paris, L. Jaenicke, Cologne; P. Jollès, Paris, C. Veeger, Wageningen

European Journal of Biochemistry reports the most up-to-date research results to the entire basic biomedical sciences community. One of the most cited journals in the field, it has become the source for researchers who must stay abreast of experimental and theoretical developments as they occur. Every issue presents the latest findings in: nucleic acids research, protein synthesis, and molecular genetics, protein chemistry and structure, enzymology, carbohydrates, lipids, and research with other natural products, physical biochemistry, membranes and bioenergetics; cellular biochemistry and metabolism; developmental biochemistry and immunology. New methods applicable to biochemical problems are also published.

European Biophysics Journal

(Continuation of "Biophysics of Structure and Mechanism")
Managing Editor: P. Bayley, London

The policy of the journal is to publish papers in the field of Biophysics, where Biophysics is defined as the study of biological phenomena by using physical methods and concepts. The primary goal is to advance the understanding of biological structure and function by application of the principles of physical science, and by presenting the work in a biophysical context. Principal areas of interest are: molecular structure and interactions; membrane and receptor biophysics; thermodynamics and energetics of biological processes; and theoretical biophysics.

MGG Molecular & General Genetics

An International Journal
Continuation of Zeitschrift für Vererbungslehre. The First Journal on Genetics - Founded in 1908
Managing Editors: H. Saedler, Cologne, H. Böhme, Gatersleben

MGG has for many years been a must for scientists wishing to keep up with the rapid process in the genetics of prokaryotes, including plasmids, mitochondria, plasmids, "jumping genes", and transposons. Background research in the molecular genetics of eucaryotes - and its practical application in genetic engineering - has recently gained increasing importance in the journal. Biotechnicians, microbiologists, virologists, and biochemists who wish to stay abreast of the latest results in molecular genetics have found MGG particularly useful.

Carlsberg Research Communications

Continuation of "Comptes Rendus Des Travaux Du Laboratoire Carlsberg" Founded 1878
Editorial Board: S. O. Andersen, H. Klenow, E. Lund. Production Editor: S. W. Rasmussen

The **Carlsberg Research Communications** can look back with justifiable pride at a tradition of publishing important research results, among them Kjeldahl's method for nitrogen determination, Christian Hansen's pure cultures of yeast, and Linderström-Lang's concepts of protein structure and enzyme function. Today, **Carlsberg Research Communications** is a source of comprehensive information on the work of the Carlsberg research establishments. The laboratories are involved in fundamental and applied research in the fields of biochemistry, cell and molecular biology, genetics, microbiology, and plant and animal physiology.

Chromosoma

Founder and Senior Editor: H. Bauer, Hannover
Managing Editors: W. Beermann, Tübingen; W. Hennig, Nijmegen; J. H. Taylor, Tallahassee

A link between two fields of research.

Chromosoma is a leading forum for contributions to the field of nuclear and chromosome research. **Chromosoma** publishes articles utilizing cytological, cytogenetic, biochemical, and molecular approaches, as well as ultrastructural studies. For more than 40 years, researchers have depended on the journal to keep them up-to-date on the latest advances in the field. High editorial quality is matched by high-quality printing and excellent reproduction of illustrations. Now in a new and enlarged format, **Chromosoma** continues its time-honored tradition of excellence by regularly disseminating original research at the forefront of the field.

Applied Microbiology and Biotechnology

Continuation of the "European Journal of Applied Microbiology and Biotechnology"
International Editors: For Europe, Africa, Australia, New Zealand, the Near East: H. J. Rehm (Editor-in-Chief), Munster, K. Esser, Bochum, W. Schönborn, Frankfurt. For the Americas: A. L. Demain, Cambridge, MA. For Japan, the Far East: A. Kimura, Kyoto

Applied Microbiology and Biotechnology is an international journal presenting research articles on topics including: biotechnology and bioengineering using microorganisms or parts of microorganisms, industrial microbiology (research and development), microbiology of sewage and food microbiology. **Applied Microbiology and Biotechnology** also features theoretical articles with direct relevance to experimental studies in applied microbiology and a special section of short communications which appear six weeks after acceptance.

Plant Cell Reports

Managing Editor: For European Countries: K. Hahlbrock, Cologne. For Countries outside Europe: O. L. Gamborg, Belmont

For researchers in all areas of the plant sciences, **Plant Cell Reports** presents original research results in biochemistry, physiology; molecular biology, cytology, genetics and genetic engineering, phytopathology, plant/microbe interactions and morphogenesis, including plant regeneration from protoplasts, cells, tissues, and organs. Contributions are published on average within six weeks of receipt of the final version. This rapid publication enables industrial and academic researchers to stay abreast of developments as they happen by subscribing to **Plant Cell Reports**.

Between fact and passion

Alan Cottrell

No Immediate Danger: Prognosis for a Radioactive Earth. By Rosalie Bertell.

The Women's Press, 124 Shoreditch High Street, London E1 6JE: 1985.

Pp.435. Hbk £11.95; pbk £5.95.

Power Production: What are the Risks? By J.H. Fremlin.

Alan Hilger: 1985. Pp.318. £22.50, \$33.

How extraordinary it is that two such books as these, written by obviously sincere, intelligent, dedicated and independent authors on the same scientific subject—the risks to the general public of nuclear radiation—should reach such diametrically opposite conclusions. The ground they cover, particularly the biomedical effects of radiation from nuclear power production, is virtually the same, although Dr Bertell's text extends to nuclear weapons production and testing, which she regards as inseparable from nuclear power, and Professor Fremlin's covers in some detail the risks from other methods of energy production, which are dealt with only cursorily and optimistically by Dr Bertell. The difference between the books is all the more extraordinary considering that, for both authors, the preservation of the natural world and its resources is a major objective, as is also the raising of the standard of living in the Third World. Furthermore, both see nuclear warfare as a total catastrophe for everyone. Yet, for Fremlin nuclear power is one of the few bright hopes for mankind on an overcrowded planet, whereas for Bertell it is an ultimate evil, to be attacked with the zeal of a crusader.

Fremlin's is a scientist's book. Cool analysis and numerical estimation are its weapons, used with great skill and elegance to expose many a foolish notion or false argument; for example, that 1 kg of plutonium would be sufficient to kill off all life on Earth. Thus

The natural uranium, radium and polonium in the ocean give off about 40 alpha particles per gram of sea-water per year. One kilogram of plutonium distributed in the oceans of the world . . . would give about 1 alpha particle per gram in 50,000 years [p.263].

In addition to his opposition to the unnecessary use of fossil fuels, Fremlin's main bias is "in favour of facts" and it is this that has led him to expose and attack false arguments used by anti-nuclear campaigners and disgracefully irresponsible treatments by the media, such as the blatant distortion presented by Yorkshire Television in Britain on 1 November 1983 (p. 275).

Dr Bertell is a scientist but hers is not a scientific book. It is a tirade and manifesto, brilliantly written, but with the set mind of the zealot. Passionate description and harrowing anecdote are her weapons, used with great skill and vividness to re-

mind the reader of what must never be forgotten; of the immense horrors of Hiroshima and Nagasaki. But Bertell treats inconvenient facts more disdainfully than Fremlin. Thus, about the genetic effects of radiation she writes

the data accumulated at Hiroshima and Nagasaki did not give the desired answers. Either through ineptitude or loss of survivors of the bombing . . . the researchers failed to find any severe genetic ills . . . [p.47].

If the facts do not suit the argument, so much the worse for them! The passion also

Power of good? Part of the British Nuclear Fuels Sellafield site in Cumbria, UK.

leads to some surprising assertions. Thus, mankind's nuclear activities have caused acid rain (p.56), the change in the El Niño ocean current (p. 102), and earthquakes (p. 163), as well as 16 million casualties. It is all a conspiracy of militaristic governments, especially Western ones. Even Pearl Harbor was a tactic of the United States designed to strengthen the fighting attitude of American people (p.151).

In a sense, these two books re-enact the classical contest between heart and head in their attempts to find a better future for mankind. Bertell advocates the Utopian future of a global village in which

the fundamental human needs for food, shelter, clothing, medical care, education, work and social dignity are met, so that the tremendous human potential for creativity, art,

science and culture is freed [p.295].

Magnificent, but is it not what mankind has always wanted? And how do we get it and maintain it? Bertell's answer is that

the money for food and celebration of life is being needlessly squandered on weapons and unneeded technological mega-projects [p.296].

Beating swords into ploughshares has been a desirable goal for endless generations and in each new one it has stumbled against the same old problem; human aggressiveness. This is why the heart is not enough. Its solutions are idealistic, planned for angels, not human beings. The head has also to play its part, to seek realism and practicality in the face of human nature as it stands. Peace with goodwill is what Bertell wants, but these may be beyond mankind's reach at present, in which case the grudging peace without goodwill that now exists between the nuclear superpowers may be the best that we can realistically have. But for Bertell, the concept of deterrence is simply not admitted; she is sure that the nuclear powers are preparing to go to war, not trying to dissuade each other from war, in spite of the fact that the European corner of the globe—traditionally a most belligerent region—has enjoyed an unprecedented period of freedom from war throughout the nuclear age.

Fremlin's goals are more limited but more attainable. The people of the world need energy. The big and rapidly multiplying poor in country villages in Africa and Asia need cooking fuel, clean water, practical education and time.

Kerosene and coal are alternatives to the destruction of the forests and the rich countries should be systematically planning to conserve these as effectively as possible and as soon as possible. Compared with the disastrous effects inevitable in an overcrowded world, none of the health hazards of any form of energy production are of any importance at all . . .

The Third World can be helped in this respect

. . . if the richer countries use as much wind and solar energy as they can, develop nuclear energy . . . and use nuclear electricity to replace oil, coal and gas . . . [p.280].

Both books brilliantly expound their author's views but it seems likely that both will fail to persuade unsympathetic readers to change theirs. Fremlin's sophisticated rapiers, needle-sharp though they are, are unlikely to pierce the hermetic seals in which the anti-nuclear protesters have insulated themselves against contamination from uncongenial scientific facts. And the unrelieved damning of all things nuclear by Bertell appears too obsessive to be convincing. To this reader at least, the truth seems less likely to dwell among her passionate advocacies than among Fremlin's cool arithmetic. □

Sir Alan Cottrell is Master of Jesus College, Cambridge CB5 8BL, UK.

Myth, magic and the common solution

Anthony W. Clare

Sherlock Holmes and the Case of Dr Freud. By Michael Shepherd. Tavistock: 1985. Pp.31. Pbk £2.95, \$5.95.

In Nicholas Meyer's *The Seven Per Cent Solution*, Sherlock Holmes, suffering from a severe mental disorder with delusional ideas concerning the machinations of a harmless Professor Moriarty, meets and is treated by Sigmund Freud who is at the time a young physician in Vienna earning a reputation for himself treating the neuroses by an exciting new method of exploration. Cured by the treatment, Holmes joins forces with Freud and together they engage in a successful hunt for a villain who is attempting to precipitate a world war.

Michael Shepherd, Professor of Epidemiological Psychiatry at the Institute of Psychiatry in London, opens what is a deceptively temperate essay with this revisionist view of Conan Doyle's hero. The reason he does so is quite simply that he is about similar business with regard to the sage of Vienna and the founder of psychoanalysis. Sherlock Holmes made the external world coherent by solving mysteries using a method of procedure

which, although appealingly labelled as deductive and logical, was in actual fact intuitive and illogical. However, so attractively human was it that it was and continues to be enormously popular and enjoyable in contrast to the numbing tedium of the real process of detection. Freud, likewise, appeared to make the world comprehensible by solving internal mysteries by a method which, Shepherd argues, was no less intuitive and illogical whatever the claims for scientific status made by Freud and his successors on its behalf. In precisely the sense that Holmes is a caricature of the real life detective, so Freud is a caricature of the psychiatrist.

However, there is more to the link between the fictional private eye from Baker Street and the actual therapeutic ear from the Berggasse. Both Holmes and Freud are the stuff of which heroes are made. Shepherd quotes Brigid Brophy and her view that the cause in which the modern detective employs his method and skill remains the same as that in which the Greek hero used his magic powers — "the deliverance of the population from a threat". In sociological terms, the detective story offers its readers a reassuringly comprehensible and predictable world in which those who try to upset the established order are always detected and punished. Freud's great case-histories read like stories in a Holmesian omnibus and a contemporary novelist, D. M. Thomas, has gone so far as to argue that in his clinical accounts Freud was often fictionalizing, as intent on getting "a good story, a well-shaped classical Greek story, as to get at the truth". Freud and Holmes, Shepherd suggests with more than a touch of mischief, are examples of Nietzsche's *ubermensch*, the new man, detached, quasi-omniscient, a contemporary hero of an ancient legend.

It is an effervescent, provocative, humorous yet profoundly serious argument, and Shepherd elegantly draws on the sympathetic effusions of many of the literary supporters of psychoanalysis to illuminate his view that psychoanalysis, wherever it ultimately belongs, appears more at home within the sphere of myth than of medicine. Others have had the same idea (for example an equivalent argument is mounted in Ernest Gellner's recently published *The Psychoanalytic Movement*), but few have made the case with such an economy of words and breadth of scholarship. To those who know Shepherd and his work, this lively appetizer will maddeningly remind them of the more substantial meal he could cook if the spirit but moved him. Disciples of Freud and psychoanalysis may well breathe a sigh of relief that to date it has failed to do so. □

Anthony W. Clare is Professor of Psychological Medicine at St. Bartholomew's Hospital Medical College, West Smithfield, London EC1A 7BE, UK.

The fitful gleam

P. W. Hawkes

Statistical Optics. By Joseph W. Goodman. Wiley: 1985. Pp.550. £49.85, \$59.80.

FLICKERING, glistening, twinkling, shimmering: the literary vocabulary of optics should lead us to expect statistics to play a large part in the subject even if the scientific language is more sober. There are indeed branches of optics — coherence, speckle, some image restoration methods, image compression, some aspects of pattern recognition, weak signal detection — which require a thorough knowledge of statistics, but the first books on probability with special reference to optics have appeared only very recently. The first, *Probability, Statistical Optics, and Data Testing*, written by B. R. Frieden and published by Springer-Verlag, appeared in 1983 and set a very high standard. Although Goodman's new text contains some material that is also to be found in Frieden, the two books are otherwise very different in coverage.

Statistical Optics opens with a brisk account of probability theory and random processes, written in the spirit of a revision aid. Individual chapters are then devoted to first-order statistics, the traditional study of temporal and spatial coherence in terms of second-order statistics, situations in which higher-order coherence arises, image formation with partially coherent light and the phase problem, propagation through random media and, finally, the detection of weak optical signals.

The ratio of optics to statistics is uneven. The chapter on first-order properties is a successful attempt to inculcate statistical thinking habits into students of optics, through the study of thermal light and laser light. The following chapter, on coherence, follows the reasoning made familiar by such standard texts as Born and Wolf's *Principles of Optics* (Pergamon, 1980) and the same is true of most of the later chapter on effects due to partial coherence in imaging systems. The latter concludes with a very brief account of phase retrieval and a slightly longer section on speckle. In the case of phase retrieval, there is hardly any discussion of the extremely important problem of noise in the various reconstruction methods, which is a disappointing and surprising omission because this is an eminently statistical topic. The chapter on higher-order coherence (of which subject it is distinctly less easy to find an elementary account) is much more useful.

The two concluding chapters, on imaging through randomly inhomogeneous media and fundamental limits in photoelectric light detection, are genuine statistical optics, in which the interdependence between the two fields is shown clearly. Goodman leads us through the theory of

random amplitude and phase screens and then goes on to examine propagation through thick layers of turbulent material, typically the atmosphere. The discussion concludes with an analysis of stellar speckle interferometry. In the final chapter, he presents the semi-classical theory of photodetection, including photo-counting statistics, the notion of degeneracy parameter, and noise limitations in various kinds of interferometry.

The text is clearly and interestingly written, but one serious criticism remains (probably reflecting more on the status of optics in university physics curricula than on Professor Goodman): this is not a complete optics course, so students must presumably attend others in which they could reasonably be expected to learn about partial coherence and its propagation. Such topics could therefore have been covered much more concisely, leaving space to deal thoroughly with material more likely to be new: the phase problem, super-resolution, and the host of statisti-

cal methods and notions used in image processing.

For physicists, then, *Statistical Optics* will be welcome as a guide to the parts of statistics needed in optics, but it does not go deep enough into the various applications for the student who plans to make optics his career, or at least the subject of his PhD research. For the electrical engineering community, however (and Professor Goodman's chair is in this subject), the book probably provides a useful initiation into the optical world for those whose preoccupations bring them into contact with the topics covered but who do not need to go into them too deeply. There is thus still room for a book in which the author assumes that his readers have mastered the statistics in this book, or in Frieden's, and are now ready for a thorough examination of statistical optics. □

P. W. Hawkes is Maître de Recherche at the Laboratoire d'Optique Electronique du CNRS, BP 4347, F-31055 Toulouse Cedex, France.

A life in theory

Esther R. Phillips

The Mathematics of Sonya Kovalevskaya. By Roger Cooke. Springer-Verlag:1985. Pp.234. DM96, \$29.80.

SONYA Vasilievna Kovalevskaya (1850–1891) was a mathematician, poet, novelist, dramatist, political tract writer and, some would add, revolutionary. She embraced the nihilism of the 1860s, with its optimistic, perhaps naïve, faith in the power of science and reason to establish a better society, and set out, against great odds, to obtain the university education that would enable her to take part in the building of a new society.

In the course of her turbulent and sometimes melodramatic life, Kovalevskaya contracted a fictitious marriage (1868) which permitted her, along with her sister and friends, to travel abroad to receive the university education denied them in Russia. Barred from attending classes at the University of Berlin (as were all women), she persuaded Karl Weierstrass, one of the leading mathematicians of his time, to give her private lessons covering the material he presented in his university lectures. Her studies were abruptly interrupted in 1871 when she journeyed to be at the side of her sister, an active participant in the short-lived Paris Commune; here Kovalevskaya served as a nurse for five weeks.

Returning to Berlin she resumed her studies, and under Weierstrass's direction she received a doctorate in mathematics (the first awarded to a woman) in 1875. A five-year break from mathematics followed, during which she returned to Russia, had a child, engaged in disastrous real

estate speculations, wrote several non-mathematical works and plunged into a frenetic social life in Petersburg. With the help of Weierstrass and G. Mittag-Leffler (also a former student of Weierstrass) she obtained a position (the first woman to do so) at the University of Stockholm, where, in 1889, she was appointed professor for life. The previous year she had received the Bordin Prize of the Paris Academy of Sciences for her memoir on the rotation of rigid bodies.

Finally, in 1889 she was elected to the Petersburg Academy of Sciences (again, a first for a woman) as corresponding member. At the time of her sudden and untimely death in 1891, Kovalevskaya was at the height of her career — an “international celebrity”, as Roger Cooke describes her (p.116).

In the book Cooke has provided a complete account of Kovalevskaya's work and a sympathetic, but not adulatory, assessment of it. Although numerous articles with biographical details have been published, there is only one full length biography in English (with almost

no discussion of her mathematics), A.H. Koblitz's *A Convergence of Lives* (Birkhäuser, 1983).

By describing in some detail the investigations of her predecessors, the author has quite correctly presented Kovalevskaya's achievements in a proper historical context. For example, in discussing one of her best known results — usually referred to as the Cauchy-Kovalevskaya theorem — he distinguishes between the modern textbook version (that it is an existence and uniqueness proof) and what Kovalevskaya, working within the Weierstrassian tradition, had set out to do, namely to demonstrate how analytic functions could be defined by means of formal power series arising as solutions of partial differential equations. Cooke has widely supplemented the description of Kovalevskaya's results with appendices containing technical details and has provided suitable “translations” of the original results into contemporary language. However, despite the author's intention to write a book for non-specialists (p.vii), I do not believe that the more technical sections will be accessible to readers who have not (at the very least) completed a course in complex function theory.

Today Kovalevskaya's achievements have taken on something of a mythical quality, and she has been elevated to a prominent position in the feminist pantheon. Thus a valuable part of this volume contains assessments of her work made by her contemporaries, H. Poincaré, A.A. Markov, V. Volterra, G. Mittag-Leffler and (in 1926) F. Klein. Cooke generally concurs and concludes that she was

a competent, creative mathematician who produced some valuable work and a few works of minor importance, making an occasional mistake in the process... she would not seem quite so remarkable if she had lived a century later, when no one is surprised to see a competent woman mathematician [pp.178–179]. □

Run to ground — stick figures traced from movie films showing normal running (left), and a perturbed form of running (Groucho running) in which the aerial phase of the gait and the bumpiness of the ride are reduced but the metabolic cost is higher. The illustration is taken from a paper in *Design and Performance of Muscular Systems*, recently published by The Company of Biologists. Distributor is The Biochemical Society, price is £25, \$60.

Burning conditions

D.B. Spalding

The Mathematical Theory of Combustion and Explosions. By Ya. B. Zeldovich, G.I. Barenblatt, V.B. Librovich and G.M. Makhviladze. Consultants Bureau (Plenum): 1985. Pp.597. \$95, £90.25.

IN ESSENCE, the mathematical theory of combustion is simple: molecules interact, and are created or destroyed, as a consequence of the reactions studied by chemical kineticists; these sources and sinks give rise to concentration and temperature gradients which engender diffusional fluxes, of the kind represented by the laws of Fick and Fourier; simultaneously, either because of the density changes or of conditions imposed at the boundaries, the products and reactants are set in motion in a manner governed by the Navier-Stokes equations; the high temperatures give rise to radiative transport of energy in accordance with the classical laws; and the interchanges of mass, momentum and energy with the surroundings can also be expressed quantitatively.

A given combustion phenomenon can therefore be represented by an established set of simultaneous partial differential equations, complicated by the fact that many of the included variables (for example density, concentrations, temperature) are linked by known algebraic relations expressing the nature of the materials in question. Once the initial and boundary conditions have been fully worked out, the problem in question is then ready for solution.

Of course, the non-linearity of the equations, and the multi-material, multi-dimensional character of most combustion phenomena, demand the use of numerical methods and of powerful digital computers. A consequent danger is that the employment of such formidable apparatus will so distract and overburden the theorist that he fails to achieve that perception of interrelationships, and ability to anticipate outcomes, which we call "understanding".

Any combustion specialist who wishes to strengthen his understanding will do well to study the present book. Soviet scientists have done much of the pioneering research on this subject, particularly in the formulation of concepts and provision of explanations of major phenomena. The senior author has been especially prominent (with Semenov, Frank-Kamenetskii, Shchelkin, Vulis and others) while his co-authors too have themselves made notable contributions.

That pioneering work was performed before electronic digital computers were available, for which reason the mathematical formulations had to be simplified; but it was conducted with realism and intelligence, and without extremism. Just

enough of the physics was retained (and especially the steep temperature dependences which give rise to nonlinearity) for the important phenomena of ignition, propagation, instability and extinction to be understood; and simple approximate methods of solution were devised for the resulting equations.

The book retains many of the virtues of the early works. But although it pays some attention to more recent trends and preoccupations, it does not follow them very far. The reader will therefore find little about theories of turbulent combustion; and recent advances in large-scale computer simulations of flames are not mentioned.

The original Russian edition of the book appeared in 1980. Its lucidity has been well preserved in the English translation and it can be read with both pleasure and advantage by combustion scientists in the Western world, several of whom will find that ideas which they have attributed to themselves or their contemporaries were already thoroughly understood a generation ago. The authors have, incidentally, addressed a graceful preface to their Western readers, while their introduction, which is the same as that of the Russian edition, reveals their full awareness that combustion is a truly international science. □

Fit for survival

John Hearn

Reproduction in Mammals, 2nd Edn. Book 4, Reproductive Fitness. Edited by C.R. Austin and R.V. Short. Cambridge University Press: 1985. Pp.241. Hbk £22.50, \$39.50; pbk £8.95, \$14.95.

THE success or failure of reproduction is crucial to survival or extinction, and thus of immense evolutionary importance. Knowledge of the process is also of great consequence in the management and conservation of species diversity in an ever more crowded world. This will continue to be a central question during the next 50 years, over which the world's human population will double to nearly nine thousand million. Much of the increase will take place in developing countries that now provide the remaining homelands of many exotic species.

Our current understanding of reproductive strategies, species variations, the genetic, behavioural and immunological factors in reproductive fitness, and the influence of senescence, is well presented in this volume, the updated version of Book 4 of the first edition of *Reproduction in*

Mammals (published in 1972 under the title *Reproductive Patterns*). It is virtually a different book: two authors of the original complement remain and there are now seven chapters instead of five. All of the contributions are valuable, but among the newcomers I particularly enjoyed the chapters on genetics (Roger Land), environment (Brian Follett) and reproductive strategies (May and Rubenstein). Revision of the series as a whole continues next year with the appearance of the fifth volume, to be entitled *Manipulating Reproduction*.

While we are rapidly improving our appreciation of general principles, we are still desperately ignorant of precise details of the basic factors that limit survival of individual species. Among mammals alone we have an adequate understanding of fewer than 50 of the 4,000 species, including those on which our agriculture and biomedical sciences are based, and our domestic pets. It is ironic that this knowledge has contributed enormously to the success of our own species in helping us to overcome all natural environmental constraints, but in consequence threatens the survival of most other species. There is a pressing need to define the essential requirements of key species, so that conservation and management policies for the shrinking wildernesses genuinely meet the needs of these species and of others that share the same territory. A hard, quantifiable, scientific approach, at the fundamental level achieved in this book, is critical for the future of animals, including man.

To quote from Roger Short's contribution (Chapter 2, on species differences):

Readers ... will have been struck by the enormous diversity of reproductive mechanisms across mammalian species. About the only common factor is that, somewhere along the line, a spermatozoon meets an egg and so a new individual is formed. Everything else is subject to enormous variability, so that generalisations become impossible. This may act as a deterrent to the faint hearted, who are baffled by complexity; in reality it should be seen as an exciting challenge, encouraging us to probe deeper for the reasons underlying the diversity.

The strength of this book, and of the series of which it is part, is that a bewildering complexity and variability of species, physiological mechanisms and scientific disciplines is made readable, understandable and exciting. The contents are right up to date and point the way to further research development. While the book is aimed primarily at an undergraduate audience, research workers and lecturers will also find it invaluable. As a definitive text in a fast-moving field, I commend it as required reading for those interested in reproductive biology. □

Charting the decline in British science

from John Irvine, Ben Martin, Tim Peacock and Roy Turner

Recent data on the comparative scientific performance of different nations suggest that the decline in British basic science apparent during the 1970s began to level off at the start of the 1980s. However, rather than heralding the beginning of a revival, the evidence suggests that this is merely a temporary halt to the long-term slide.

It is now almost conventional wisdom that British science is in a state of crisis. Recent leading articles in *Nature*, for example, have had a tone of desperation, with headlines such as "University paymasters discredited — the British government's latest policy document on higher education is a disgrace", "More crisis for UK research", and "Parliament's chance to act". A similar, if more restrained, note of despair has been sounded by the Advisory Board for the Research Councils (ABRC) in its latest report, *Science and Public Expenditure 1985*, which was submitted in June to the Secretary of State for Education and Science. In unambiguous terms, this stated that, "We believe that Parliament, the Government and the country as a whole are complacent about the current financial straits of the dual support system" (for financing research in universities).

In these and other analyses of the situation now confronting British science, most attention has been focused on inadequacies of the funds and other inputs to research. Largely for lack of data, less has been said about the effects of financial constraints on the outputs from science. We attempted to remedy this last year in a study for the ABRC which made use of a range of research output indicators (world shares of publications and citations, and figures on Nobel Prizes and patents), seeking thus to provide systematic information on long-term trends in British science.

The evidence suggested that, during the latter half of the 1970s, Britain's basic science declined appreciably, both in regard to relative output of publications and in their impact on the international research community. It was argued that the government may not be providing sufficient support for research (or at least not concentrating it in the right places) to ensure the successful development of new core technologies vital to the long-term survival of British industry.

The subsequent public interest in the results of the study (see *New Scientist*, 1429, pp.25–29, November 1984) apparently reflects a growing realization that, despite all the limitations of scientific output indicators, it will be necessary to make much greater use of systematic information on research performance in for-

mulating a coherent national research policy if Britain is to ensure that the scientific needs of new technology-based industries are met. Trying to steer publicly funded research using only the mechanism of scientific peer-review (or "the informed prejudices of wise men", as it has been aptly described), while totally ignoring quantitative input and output indicators, is somewhat like trying to run the economy using only the judgements of a committee of senior industrialists.

In what follows, we update the figures on Britain's performance in basic research to the end of 1982, and provide more detailed data on trends in some of the main fields of science. The work involved was supported by a consortium of British learned societies who have set up an informal working party (Ad Hoc Working Group for Research Funding, AGREF) under the chairmanship of Professor J. Lamb (St Andrews University, UK) to examine government support for science.

Measuring performance

Perhaps the most readily accessible data on national research outputs are the publication and citation indicators contained in the National Science Foundation's *Science Literature Indicators Data Base*. This is compiled by CHI Research on behalf of NSF for use in the biennial US *Science Indicators* report, and is based on the *Science Citation Index* produced by the Institute for Scientific Information (ISI). (This database is the source of the material pre-

sented in Tables 1–7, and a copy of it is held at the Science Policy Research Unit, University of Sussex.) The primary dataset covers some 2,000 of the world's leading scientific journals over the decade 1973–82, and contains figures on numbers of publications and citations for more than 190 countries and geographical regions, broken down into eight main scientific fields (for example, physics) and, in the case of the publication data, into approximately 100 subfields (for example, optics).

The use of such bibliometric data to indicate research output in basic science entails a number of assumptions. One is that most new scientific knowledge is eventually encapsulated in the form of research articles in learned journals. If this is the case, it follows that aggregate figures on the number of British publications in specified fields compared with those from other countries should give some indication of Britain's relative scientific output and, more importantly, of trends over time. A second assumption is that citation counts (that is, the number of times papers are subsequently referred to by other scientists) can be used to gauge the impact of research findings on the scientific community.

At the outset, we list three important caveats. First, the ISI data are appreciably biased in favour of English-language journals, which means that the scientific contributions of West Germany, France, Japan and, in particular, the Soviet Union

Table 1 UK world share of publications by field of research, 1973–82

Field	Percentage of total					Av.	Av.	Total %
	1973	1975	1978	1980	1982	ann. % change 1973–80	ann. % change 1980–82	
Biology	9.5	10.7	10.8	10.2	9.9	+1.1%	–1.5%	+4%
Biomedical research	9.4	9.6	8.8	8.4	8.4	–1.5%	0.0%	–10%
Chemistry	7.8	8.3	7.0	6.8	6.9	–1.8%	+0.7%	–12%
Clinical medicine	10.4	10.4	9.5	9.3	9.4	–1.5%	+0.5%	–9%
Earth and space sciences	8.1	9.5	8.9	9.5	8.9	+2.5%	–3.2%	+10%
Engineering and technology	10.7	11.0	9.4	9.5	8.6	–1.6%	–4.7%	–20%
Mathematics	7.4	8.2	7.0	7.0	7.0	–0.8%	0.0%	–5%
Physics	7.7	7.4	6.3	5.9	6.1	–3.3%	+1.7%	–21%
All fields combined	9.2	9.5	8.6	8.3	8.3	–1.4%	–0.1%	–10%

are underestimated. Second, the CHI/NSF trend data are based on an essentially constant set of journals established in 1973; papers published in entirely new journals are not covered, with the result that newly emerging or fast growing areas of science may be under-represented. This disadvantage is, however, offset by the fact that more reliable analyses of trends over time can be undertaken. (Since 1981, CHI Research has in fact compiled an alternative data series based on the 3,000 journals scanned by ISI in that year, but their analysis suggests that this larger database may be more, rather than less, biased in favour of English-language countries.) Third, since CHI Research assigns articles to fields and subfields according to the journals in which they are published, some problems can arise in relation to smaller specialities, in particular those of an interdisciplinary nature where researchers publish in a great variety of journals.

Britain's performance

Table 1 contains data on changes over the decade up to 1982 in Britain's world share of publications broken down by field of research. While there has been a decline of 10 per cent in overall world share (down from 9.2 per cent to 8.3 per cent), the picture is uneven. Physics and engineering have suffered significant decreases of 21 per cent and 20 per cent respectively, but biology has marginally increased its world share by 4 per cent over the 10 years. More encouraging, at least at first sight, is that the downward trend evident since 1975 seems almost to have levelled off in the two years since 1980, with physics, chemistry and clinical medicine apparently registering small increases. We shall return to the question of whether this halt in the downward trend is likely to continue or is merely a temporary phenomenon.

On the impact of British work on the international research community, a rather less optimistic picture emerges from the citation figures in Table 2. It can be seen that the decline which began in the 1970s has continued into the 1980s — the world share of citations for all fields combined has decreased by 15 per cent since 1973, with biomedical research, engineering and physics all recording falls of over 20 per cent. (Figures based on the 1981 journal-set are relatively consistent with these values.) Furthermore, although there had been a slight decrease in the rate of decline from 1.9 per cent per annum in the 1970s to 1.2 per cent in the early 1980s, there is little sign in the citation figures of the levelling off seen in the world share of publications.

When the figures for Britain are set against those for the other main industrialized nations, the implications of the long-term decline in Britain's basic science become all too apparent. Table 3 gives a breakdown by field of percentage changes in national shares of world publications

Table 2 UK world share of citations by field of research, 1973–82

Field	Percentage of total					Av. ann. % change	Av. ann. % change	Total % change
	1973	1975	1978	1980	1982	1973–80	1980–82	1973–82

over the period 1973–82. Japan has increased its overall share by no less than 40 per cent and the rest of the world by 9 per cent; the main losers have been Britain (–10 per cent), Canada (–8 per cent), France (–9 per cent) and the Soviet Union (–15 per cent), although in the last two cases there are likely to be appreciable biases in the statistics since French and Soviet scientists may well be preferring to publish more in domestic journals not scanned by ISI.

Such an effect would also give rise to an element of bias (probably rather smaller) in the figures on changes in national shares

of world citations given in Table 4. These suggest that Japanese researchers in all eight fields have markedly increased their impact on the international scientific community, with an overall citation share that has risen by 65 percent during the 10 years to 1982. Similarly, West Germany and the rest of the world increased their overall shares by more than 10 per cent, with France also recording a significant increase (8 per cent). Britain and the Soviet Union have again been the main losers, with declines of 15 per cent and 27 per cent respectively. One interesting feature of the table is that Japan's largest gains in

Table 5 Strengths and weaknesses in British science: share of world publications, 1982

world citation share have tended to be in fields where Britain has declined most, biomedical research, physics and engineering in particular.

One finding from our previous analysis of earlier NSF/CHI data was that the weakest parts of British basic science are heavily concentrated in areas with strategic technological importance for the future. This finding is reinforced by the updated statistics reported in Table 5. This table lists those scientific specialities in which Britain had a world publication share of more than 11 per cent or less than 7 per cent in 1982. One can see that the areas of strength are mainly in medical and biological specialities, although organic and inorganic chemistry, and electrical engineering and electronics are also quite strong. In contrast, the weaker areas are generally in more applied scientific and engineering specialities such as metallur-

gy, optics, polymer research, chemical engineering and applied physics. What is particularly alarming is the continuing rapid decline in several of these areas; in just two years since 1980, Britain's world publication share in optics dropped from 5.5 per cent to 4.6 per cent, in polymer research from 6.3 to 5.5 per cent and in chemical engineering from 6.7 to 5.9 per cent.

More systematic evidence on recent trends is contained in Table 6, which shows the research areas where Britain has either increased or decreased its world publication share by over 15 per cent in the five years up to 1982. With the exception of computer technology, the overall picture is again one of major declines in areas of science likely to prove strategically important in the future—for example, materials science, applied chemistry and physics, and electrical engineering and

electronics.

We have argued elsewhere that companies in both traditional and new industrial sectors are becoming increasingly dependent on the results of research for maintaining innovative activity and international competitiveness (see *Foresight in Science: Picking the Winners*, Pinter, London, 1984). The figures on recent trends in British science, especially those for more applied scientific and engineering research, thus give major cause for concern, particularly when set in the context of the dramatic fall that has already occurred over the last decade or so in the country's relative technological standing. One indication of the latter is the British share of foreign patents registered in the United States. OTAF data shows that, in the past 20 years, this has declined from around 20 per cent to 8 per cent, while Japan's share has, over the same period, risen from under 10 per cent to over 35 per cent, and West Germany's has remained broadly constant at about 25 per cent, as has that of France at 8 per cent. Clearly, if Britain is to compete more effectively in the international technology market, one important precondition will be an increase in the strength of its underlying research infrastructure.

Optimism

It is therefore worth looking more closely at what has happened since 1980 to determine whether there is any evidence that the long-term decline in British science shows any sign of being reversed. As noted earlier, the figures relating to the British world share of publications do initially seem to provide some grounds for optimism. From the figures in Table 1, one can see that, while the overall share fell from a peak of 9.5 per cent in 1975 to 8.3 per cent in 1980 (a fall of 14.5 per cent in five years or nearly 3 per cent per annum), the British share has remained approximately constant since 1980. Does this herald a renaissance in British science?

There are several possible explanations for this levelling-off in the relative output of British publications since 1980. One is that British scientists, perhaps imbued with a new sense of economic realism engendered by the policies of the Conservative government after its election in 1979, realized the need to increase their productivity and began to publish more research articles in international journals.

In our view, however, a more plausible explanation relates to the funds received by science. Most British academic research is supported by grants from the five research councils with indirect support provided by the University Grants Committee. Figures on research council expenditures in constant prices (calculated using the official EEC research and development price deflator) for 1970 onwards have been plotted graphically in Fig. 1, the expenditure for each year being

Fig. 1 Association between research council expenditure and UK world share of publications/citations. Source: Tables 1 and 2 on pp.6 and 19 of Butler, E. B. (ed.) *Research and Development in the UK* (Technical Change Centre, London, 1984), which are in turn based on figures published by the Central Statistical Office of the United Kingdom.

expressed as a ratio of that in 1977. As can be seen, research council expenditure grew in real terms between 1970 and 1972, before declining gradually to a minimum in 1977. In the three years up to 1980, expenditure grew slowly but steadily, but since then has fallen sharply in real terms.

Figure 1 also plots the changes in Britain's world share of publications and citations. In the case of publications, there was a peak in 1975 (three years after the peak in funding), but then a rapid fall reaching a minimum in 1980 (again three years after the trough in funding); 1981 registered a modest increase, while in 1982 the British world share began to fall again. There is thus a certain similarity between the trends over time in funding and national share of publications. It would appear that the 6 per cent increase in funding between 1970 and 1972 was reflected in the 3 per cent increase in Britain's share of publications between 1973

and 1975, while the 7 per cent decline in funds in the five years up to 1977 was associated with the sharp drop of 14 per cent in publication share between 1975 and 1980 (see Table 7). In other words, there seems to be a time lag of approximately three years between changes in expenditure and publication share. (This is the reason why the figures on publications have been normalized to 1980 compared with 1977 for funding.) Similarly, there is some suggestion of a time lag be-

tween publication and citation world shares, with the rapid fall in the former between 1975 and 1979 apparently being mirrored in a similarly sharp decline in the latter between 1976 and 1980. If there is indeed an association between research expenditure and the British share of world publications, this would suggest that the levelling off in publication output was largely the result of the 3 per cent increase in research expenditure between 1977 and 1980. Further, if such an association were to continue to hold in the future, one would expect the drop in funding since 1980 to be followed some three years later by a sharp decline in the UK share of publications. It will be interesting to see whether this is actually the case when the CHI/NSF data for 1983-84 become available in 1986. Furthermore, according to the ABRC's latest report, research council funds have continued to fall in real terms since 1983 (by perhaps 1 per cent per annum) and, on the basis of government estimates, will probably continue to do so over the rest of the decade. If the past is any guide, it seems that the UK world share of publications may decline at a somewhat faster rate over the foreseeable future.

Much more research is obviously needed to establish the existence of a direct relationship between funding and publication output and also to explore the reasons behind the fall in the British share of citations. (One reason, for example, may be the widely reported shortage of front-line research equipment in universities and research council laboratories.) Nevertheless, it is clear that one can take little comfort from what has happened since 1980 — the evidence suggests that the levelling-off in the decline of the UK world share of publications between 1980 and 1982 will prove only a very temporary phenomenon.

Over the last year, there has been a considerable growth in concern in Britain with the state of science. At the invitation

of ABRC, the Royal Society is undertaking a study of the health of British science which may provide some evidence on the extent to which the pessimistic conclusions following from bibliometric data of the type presented above are consistent with the views of the scientific community. The Secretary of State for Education and Science is, according to his speech during the 14 June House of Commons debate on science policy, awaiting the completion of that study before making his judgement about whether the quality of science in Britain has declined. Others, however, are already extremely concerned. For example, John Harvey-Jones, chairman of ICI, had this to say about a thorough review by the company of where its next science-based innovations would come from: "I think there is some evidence that the United Kingdom is sliding in the world pecking order. The evidence is still tenuous, but it has led us to start increasing our links with overseas universities that we see as centres of excellence. . . . If our suspicions are correct that the United Kingdom is no longer up at the front as it was, then that presents, in the long haul, very dangerous problems for us." (Quoted in *The Guardian*, 19th February 1985, p.24.) As one of the Members of Parliament who spoke earlier in the parliamentary debate warned, "this may be the last chance. . . to stop the catastrophe that we face as a scientific and educational nation".

We acknowledge support from AGREF, the working group convened by a number of the learned societies, and from the Leverhulme Trust and the Economic and Social Research Council, as well as assistance provided by Dr F. Narin of CHI Research. □

and 1975, while the 7 per cent decline in funds in the five years up to 1977 was associated with the sharp drop of 14 per cent in publication share between 1975 and 1980 (see Table 7). In other words, there seems to be a time lag of approximately three years between changes in expenditure and publication share. (This is the reason why the figures on publications have been normalized to 1980 compared with 1977 for funding.) Similarly, there is some suggestion of a time lag be-

Enzpack by P. Williams

ENZPACK is a computer program for the teaching and calculation of enzyme kinetics, by teachers, students, research workers and others who are interested in enzyme kinetics whether as novices or experienced workers.

ENZPACK is available for several popular microcomputers and is very easy to use, with superb graphics and comprehensive documentation

ENZPACK explores single substrate enzyme kinetics. It demonstrates the relationship between reaction velocity and substrate concentration according to the Michaelis-Menten equation for a single substrate reaction for values of K_M and V_{max} selected by the user.

ENZPACK can also be used to analyse experimental data entered by the user, to derive K_M and V_{max} values and provide graphical representation of the results. The program can thus be used in laboratory practicals or research projects.

ENZPACK uses high resolution graphics to display velocity/substrate curves and the major linear derivative plots (Lineweaver-Burk, Hanes-Woolf and Eadie-Hofstee). It gives an immediate visual appreciation of the different, commonly used ways of representing kinetic data. With a suitable large screen monitor the displays could be used to demonstrate to a class of students.

ENZPACK shows the effects of experimental error on the basic and derivative plots, demonstrating the different properties of the plots and how they are not all equally suitable for extrapolating kinetic parameters.

ENZPACK shows the effects of various types of inhibition (competitive, non-competitive and excess substrate) on the results obtained, and how the shapes of the different derivative plots are affected.

ENZPACK demonstrates clearly the derivation of the Direct Linear plot and how K_M and V_{max} are extrapolated from it.

The ENZPACK manual includes the full theoretical basis of the calculations used, plus exercises to demonstrate all the features of the program.

Package includes:

Manual plus 5 25" floppy disk (please specify Apple II; IBM PC, BBC B 40 or 80 track); or cassette for Sinclair Spectrum.

ANNOUNCE

Statstream by A. Bangham

STATSTREAM has at its heart a library of 76 procedures including data entry, graphing, text-windowing, statistical tests, function-fitting etc. These can be used very simply by:

- (1) Calling the helpful menu-driven Statpack, which enables a variety of parametric and non-parametric tests to be done, after a single data entry.
- (2) Using the 24 demonstration programs designed to teach the user all about statistics and fitting functions to data.
- (3) Writing straightforward BASIC programs to incorporate the desired procedures.

STATSTREAM is usable by, and useful for, everyone from the beginner, new to statistics and computing, to the professional statistician or research worker who wishes to incorporate the elegant STATSTREAM procedures in his own BASIC programs. It is also a first class educational tool.

Package includes:

Two packed 5 25" floppy disks for the Apple II series (3 3 DOS, min 48K RAM) (which can be used with one or two drives) plus a comprehensive manual.

The Blanchaer Clinical Case Studies

A series of simulations for the Apple II computer of clinical cases of biochemical defects in metabolism. They assume some knowledge of biochemistry, physiology and anatomy, and that case notes and textbooks can be referred to while working through the cases. The clinical orientation provides added interest and encourages students to master in depth certain aspects of the basic science which tend to be learned superficially, and only well enough to pass an examination.

Charley - presents with extreme stiffness and reddish urine (metabolic block at glycogen phosphorylase)

Lisa - has a neurological problem (phenylketonuria)

Sydney - feverish and unconscious, has two acid-base disturbances (both due to aspirin poisoning)

Mark - arrives in a coma (hyperglycemic, hyperosmolar)

Elsie - has phlebitis and dislocated eye lenses (collagen/cystathionine synthetase defect)

Walter - complains of swollen legs (oedema due to lowered serum albumin)

Dinah - found to be obese at check up

Each simulation available on one 5 1/4" disk for Apple II, 64K RAM.

Expert 4 by A. Rivers

An easy-to-use sophisticated disk-based 'Expert System' development tool for the IBM PC at an incredibly low cost.

EXPERT4 can be used to create and manipulate a knowledge base, which employs models of human reasoning or 'artificial intelligence'. It draws on deductive and fuzzy logic, multidimensional statistics and cognitive psychology. The theory behind EXPERT4 is fully discussed in the documentation which accompanies the disk.

EXPERT4 offers a spreadsheet which enables the user to create files or 'domains' each of which is made up of 'elements' which have 'attributes'. These have 'attribute values'. For example, in a domain called 'People', 'Jane' is an element. One of her attributes is 'Hair colour'. Jane has brown hair hence

'Brown' is the attribute value.

Inferencing facilities in EXPERT4 calculate and display relationships amongst the elements and attributes in terms of similarity and typicality. Any two selected items can be compared in detail for their similarity and differences. An example use would be to assist with diagnosis of a group of diseases with similar symptoms.

Other potential uses of EXPERT4 are manifold, but to give the user an introduction to the program, two completed domains are incorporated on disk as examples.

Package includes:

Documentation + 5 1/4" floppy disk for the IBM PC.

TO ORDER

Williams: ENZPACK

Manual: plus disk (please specify Apple II; IBM PC; BBC B 40 or 80 track) or cassette for Sinclair Spectrum **US \$45; UK £30**

Bangham: STATSTREAM

Manual + 2 5.25" disks (Apple II only) **US \$99; UK £66**

Blanchaer: CLINICAL CASE STUDIES (Apple II only)

Single simulation **US \$75; UK £50**

Additional simulations (same order) **US \$45; UK £30**

Complete set (7 simulations) **US \$300; UK £200**

Rivers: EXPERT4

Documentation + disk for IBM PC **US \$99; UK £66**

Prices include postage & packing.

During much of the Quaternary, the Earth's climate has undergone drastic changes most notably successive glacial and interglacial episodes. The past 150 kyr includes such a climatic cycle: the last interglacial, the last glacial and the present holocene interglacial. A new climatic-time series for this period has been obtained using $\delta^{18}\text{O}$ data from an Antarctic ice core.

ALTHOUGH continuous records of climatic and environmental conditions extending beyond 150 kyr are preserved in polar ice sheets, a reliable time series covering the whole of this climatic cycle has not yet been derived from ice cores. This results from logistic reasons, the favourable sites being located in the central regions of Antarctica and Greenland, and the technical difficulty of deep drilling.

The Quaternary has undergone successive glacial and interglacial episodes¹⁻³. Since the first Camp Century drilling in north-west Greenland⁴, five deep-ice cores reaching back to the last glacial have been recovered in Antarctica at Byrd⁵, Vostok⁶ and Dome C⁷ and in Greenland at Dye 3⁸. They have been extensively studied for their oxygen-18 content (denoted $\delta^{18}\text{O}$ expressed with respect to SMOW) and their chemical impurities, which provide valuable information about the Earth's palaeoclimate and palaeoenvironment (see refs 9, 10).

Of these cores, Camp Century seems to extend back to the last interglacial. As it was drilled down to the bedrock, however, this last interglacial ice is confined to the last few metres of the core, because of the thinning of the ice layers during their sinking in the ice sheets. The complexity of the flow lines makes it difficult to date ice cores reaching the bedrock by flow modelling only. Indirect dating techniques, based on the comparison of $\delta^{18}\text{O}$ profiles in ice cores and in deep-sea cores have recently been used⁷⁻⁹ for this purpose. A new Camp Century timescale was proposed which confirms the presence of last interglacial ice and, accordingly, indicates that the deepest part of the Dye 3 ice core was probably deposited during this period⁹. This is possibly also the case for the Devon Island core drilled through a shallow ice cap in the Canadian Arctic¹¹.

We have determined a new climatic-time series obtained from $\delta^{18}\text{O}$ analysis of a 2,083-m ice core drilled at Vostok Station by the Soviet Antarctic Expeditions. The site is located on the high Antarctic Plateau, where the ice thickness is ~3,700 m. The isotope profile covers the last 150 kyr, back to the ice age which preceded the last interglacial, and has essentially been undisturbed by flow conditions.

Vostok ice core

The Soviet Antarctic station of Vostok is located in East Antarctica (78°28' S and 106°48' E) at an altitude of 3,488 m (mean annual pressure 624 mbar; mean annual temperature -55.5°C). The present snow accumulation is between 2.2 and 2.5 g cm⁻² yr⁻¹ (ref. 12) as determined independently from a profile of artificial β activity¹³ and detailed stake measurements¹⁴.

The first series of drilling was performed down to 950 m in successive steps between 1970 and 1974. This 950-m core covers all the Holocene and part of the last glacial periods as shown by the $\delta^{18}\text{O}$ profiles obtained by Barkov and co-workers^{6,15,16}. In 1980, the drilling of a second deep hole was started which

has reached a depth of 2,083 m. The $\delta^{18}\text{O}$ measurements were completed down to 1,412 m (refs 17, 18), a depth which would correspond, from a preliminary dating, to 115 kyr BP (ref. 19).

The collaboration between Soviet and French scientists which centred around the study of this new 2,083-m Vostok ice core was initiated in 1982. Within this framework, sampling was done in the field during the 1982-83 Austral summer and pieces of ice core were sent to Grenoble. The core analysis now in progress in various Soviet and French laboratories concerns, in particular, the chemical analysis of impurities and gas bubbles including CO₂.

$\delta^{18}\text{O}$ profile

Sampling of ice for isotope analysis was done in the field (1982-83 Austral summer) by cutting a continuous slice from the length of the ice after careful cleaning. Sampling was performed on 1.5-2 m ice increments. Samples were sent in solid form to Grenoble and then melted before isotope analysis in Saclay. Two independent series of samples were obtained: (1) a discontinuous series, duplicated to check reproducibility, with one sample taken each 25 m from the surface down to the bottom of the core; (2) a continuous series between 1,406 and 2,083 m.

Oxygen-18 and deuterium determinations were simultaneously performed on all the samples. Here we will discuss the $\delta^{18}\text{O}$ results. The deuterium and deuterium-excess²⁰ results will be discussed elsewhere. The results, obtained with an accuracy of $\pm 0.15\%$ (w.r.t. SMOW), are shown in Fig. 1 as a function of the sample depth. The two sets of samples from the discontinuous series are in good agreement all along the core and their average value at each level is given. For the sake of discussion a continuous line was drawn between each point. There is excellent agreement between the continuous and discontinuous series over all the common parts indicating that the 25-m sampling interval is fine enough to extract reliable palaeoclimatic information. On the other hand, the present data are not detailed enough to document for the Southern Hemisphere such features as the abrupt environmental changes revealed in the Dye 3 ice core between 30 and 40 kyr BP (refs 9, 21).

Down to 1,400 m, the basic features of the $\delta^{18}\text{O}$ curve (Fig. 1) are similar to previously published Vostok $\delta^{18}\text{O}$ profiles^{17,18}, with the last glacial maximum around 400 m, and a $\delta^{18}\text{O}$ shift between glacial and post-glacial conditions of ~5%. However, there is a systematic shift towards lower values for the present set of data of ~3%. Such a shift has already been noticed by Dansgaard *et al.*²².

The $\delta^{18}\text{O}$ profile presented here gives a complete picture of the last climatic cycle from the end of the previous glaciation. In particular, the last interglacial with the highest $\delta^{18}\text{O}$ values around 1,825 m can now be examined in detail. For a further

Fig. 1 Oxygen-18 versus depth in the Vostok ice with the definition of the successive stages and indication of the ages corresponding to the limits between these stages. The thick line is drawn from discontinuous data (one for each 25 m), the thin line corresponds to a continuous sampling between 1,400 and 2,083 m. For explanation of A-H, see text.

description of this curve and comparison with other palaeoclimatic profiles, we will designate the successive warm and cold stages consecutively from the top of the record downwards. A striking feature of the profile is the existence of four very well-marked cold periods (that is, low $\delta^{18}\text{O}$) around 425, 975, 1,525 and 2,050 m with practically the same $\delta^{18}\text{O}$ values of around -62% . This makes the definition of the successive stages shown on Fig. 1 relatively straightforward. Starting from the top, the warm periods (hatched areas), are designated by A, C, E and G and the cold periods by B, D, F and H. Stages A and G have the isotopically richest values lying around -57 and -55% , respectively. From the solid curve (Fig. 1), one can note a sharp isotope transition ($\sim 2\%$) inside the G stage at a depth of 1,790 m. Stages E and C are relatively warm interstadial intermediate between full glacial and interglacial conditions.

Dates for the limits between the successive phases are indicated on the top of Fig. 1 (the dating method used is described below). Stage A corresponds to the present Holocene period. Stages B-F cover the last glacial. Stage G includes the peak of the last interglacial and stage H is the last part of the previous glacial.

Ice-core chronology

Many techniques, including isotope and chemical stratigraphies and flow modelling, have been used over the past 10 yr to establish dating of the Vostok ice^{16,19,23,24}. Further detailed isotope study showed that seasonal $\delta^{18}\text{O}$ variations are rapidly smoothed by diffusion²² indicating that reliable dating cannot be obtained from isotope stratigraphy. Unlike the Camp Century core, where the existence of interglacial ice relies on a comparison with deep-sea core isotope profiles, we propose to establish the timescale using an ice-flow model which is independent of other palaeoindicators.

There are two problems with this type of dating. First, for each depth the rate of accumulation at the time and in that area of origin of snow, $A(z)$, must be determined. Second, the thinning function, that is, the ratio of the thickness of a layer to its initial thickness, has to be calculated. We now describe our approach to these problems.

To estimate the past accumulation rate we adopt a procedure based on the observation that the present precipitation rate on the Antarctic plateau is strongly correlated with surface temperature. Robin²⁵ has suggested that this correlation exists because precipitation is governed by the amount of water vapour in the atmosphere circulating above the surface inversion layer. As discussed by Lorius *et al.*⁷ and Jouzel and Merlivat²⁶, there is a link between the temperature of formation of precipitation and its oxygen isotope ratio. Assuming that the same relationship has held in the past, it is thus possible to estimate past accumulation rates from the $\delta^{18}\text{O}$ profile of the ice. Raisbeck *et al.*²⁷ and

Fig. 2 Surface and bedrock topography along the Ridge B-Vostok axis (lower curve) and the thinning function (top right) expressed as a percentage of the initial thickness, with (solid line) or without (dotted line) taking into account this topography.

Yiou *et al.*²⁸ in this issue have noted that the ^{10}Be concentrations of ice at Dome C and Vostok are consistent with accumulation rates deduced by such procedures. We thus estimate the accumulation function in the following way. First, the temperature of formation of precipitation, T_F , is estimated along the profile as described by Lorius *et al.*¹⁰. Then, the accumulation rate, $A(z)$, is calculated from the product of its present value, $A(0)$, times the ratio of the derivatives of the saturation vapour pressure—with respect to $T_F(z)$ for the time of precipitation and with respect to $T_F(0)$ for the present conditions. This formulation is derived from a simplified unidimensional model neglecting the possible changes in circulation intensity above the area of precipitation.

The use of a two-dimensional glaciological model is well suited to the Vostok area as the ice flowlines are roughly parallel in this region of East Antarctica²⁹. The change of the ice thickness upstream of the drilling site is important because of the bedrock topography³⁰ (Fig. 2) and this has been taken into account when using the analytical model of Lliboutry³¹. Finally, ice-core dating is established using an iterative process. Starting from a plausible dating obtained from a simple one-dimensional model the ice origin is determined. Then, the thinning function is calculated and the ice redated all along the core. The process is repeated using the new dates as the initial conditions until the initial and final datings converge.

To illustrate the influence of the bedrock topography, the thinning functions with (Fig. 2, solid line) and without (Fig. 2, dotted line) taking into account this topography can be compared. This demonstrates the strong effect of bedrock topography between 500 and 1,000 m. For these calculations, ice velocities were approximated by their average values using mass continuity over the entire climatic cycle.

The results are presented in Fig. 3 for three values of the present accumulation. The annual accumulation (expressed with respect to its present value) is obviously correlated to the $\delta^{18}\text{O}$ profile with lower values during glacial periods as previously stated from Dome C ice-core studies^{7,27} and independently proposed at Vostok from ^{10}Be measurements²⁸.

From available data¹², an average value of $2.3 \text{ g cm}^{-2} \text{ yr}^{-1}$ was adopted for the present accumulation rate, giving ages of 98 kyr BP at 1,412 m (that is, significantly younger than the previously estimated¹⁹ 115 kyr BP) and of ~ 160 kyr BP for the bottom of the core.

This accumulation value, although uncertain given the very short period (<10 yr) over which this parameter was determined, seems to be a reasonable average over the Holocene period. Our dating puts the end of the last climatic transition at around 10 kyr BP which compares well with the same event recorded in the Dome C East Antarctic core at ~ 10.5 kyr BP (ref. 7). The uncertainty on this value is thus $\sim 5\%$, a value which would give a lower limit for the relative dating uncertainty all along the core. Dating of the first part of the core is also indirectly supported by the existence of a dust content maximum between ~ 13 and 26 kyr BP (ref. 32), a period of aridity over Australia³³.

However, other sources of errors come from estimations of accumulation changes and, to a lesser degree, of the thinning function. Thus, the age of the bottom of the core is probably not known with a precision better than 10–15 kyr.

Palaeoclimatic information

The isotope content of polar snow is primarily governed by T_F , but it also depends^{9,10,34,35} on several other parameters such as the origin and dynamical history of the air masses and the microphysical processes leading to snow formation. A way of reconstructing the full, space-time variations of isotope contents of vapour and precipitation is to incorporate the isotope cycles in a general circulation model of the atmosphere (GCM)³⁶.

Until this new approach is fully developed, the climatic interpretation must be based on $\delta^{18}\text{O}$ -temperature relationships observed in modern precipitation and/or isotope models which give only a simple schematic overview of the dynamic history of the air masses. Although aware of the limitations, we are relatively confident that when the two methods are combined major temperature changes, such as those accompanying glacial-interglacial transitions, can be estimated. This is especially true for central East Antarctica for several reasons. First, the observed $\delta^{18}\text{O}$ -temperature relationship³⁷ is quite linear (correlation coefficient, $r=0.989$ for the -20 to -55°C interval) and its slope can be correctly explained on a theoretical basis applying a recently developed kinetic isotopic model²⁶. Second, the ice thickness has probably undergone only minor fluctuations and the ice origin can be reliably reconstructed. In addition, our confidence in a temperature reconstruction is reinforced in the Vostok core by the good agreement between accumulation changes derived by transforming the $\delta^{18}\text{O}$ profile into a temperature profile and those derived from ^{10}Be (ref. 28).

After correcting for the change in $\delta^{18}\text{O}$ of the oceanic water (maximum 1.6%)³, this temperature reconstruction is carried out as in ref. 10. With this interpretation, the glacial-interglacial surface temperature shifts are $\sim 10^\circ\text{C}$ for the H-G transition ($\delta^{18}\text{O}$ shift of 6.5%) and 8°C for the B-A transition ($\delta^{18}\text{O}$ shift of 5%). C and E interstadials are around 2 and 4°C , respectively, warmer than full glacial conditions and the four cold stadials H, F, D and B are within $\sim 1^\circ\text{C}$. The peak of the last interglacial maximum is significantly warmer than the Holocene period. The difference is estimated to $\sim 3^\circ\text{C}$, 1°C of this being due to the formation of the interglacial ice 100 km further inland (Fig. 2). All these values do not take into account the possible variations in the ice-cap altitude. These corrections will be done, if necessary, from the total gas content which is under investigation. Preliminary data (D. Raynaud, personal communication) suggest that the isotope signal is essentially of climatic origin which is independently corroborated by some studies tending to demonstrate the relative stability of the East Antarctic ice sheet at the considered timescale^{38,39}.

Comparison with other ice cores

Concerning the transition between the last glacial maximum (around 18 kyr BP) and the Holocene periods (B-A in our terminology), the present results confirm the excellent agreement between the two East Antarctic sites, with a $\delta^{18}\text{O}$ shift, before corrections, of 5.4% at Dome C⁷ and of $\sim 5\%$ at Vostok, and to a lesser degree with the Byrd West Antarctic site (shift of 7%)⁵. The inferred surface temperature change for Antarctica is ~ 8 – 10°C . These shifts agree well with those deduced for high southern latitudes from GCM ice-age modelling^{40,41}, although recent simulations predict lower temperature shifts^{42,43}. The isotope shift is also 7% in southern Greenland (Dye 3)^{8,9}. The higher values ($>10\%$) registered in northern Greenland and adjacent regions (Camp Century, Devon Island) can be partly attributed either to a change in the elevation of the ice formation⁴⁴ or to a more drastic climatic change in this area than in southern Greenland or in Antarctica⁹.

For the last glacial, a detailed comparison with other ice cores is difficult because only 7% of the Vostok core was analysed down to 1,400 m. In any case, it would be necessary to discuss

Fig. 3 a, Initial thickness of annual layers (accumulation rate $A(z)$); b, thickness of these annual layers in the core. Both a and b are expressed with respect to the present (accumulation rate $A(0)$); c, depth-age relationship for different values of $A(0)$ in $\text{g cm}^{-2} \text{yr}^{-1}$.

thoroughly the successive timescales derived for the Byrd, Camp Century and Dye 3 cores. Such a comparison will be undertaken in the near future when a continuous profile becomes available for the Vostok core.

The apparent time elapsed between the interglacial peak and the following $\delta^{18}\text{O}$ minimum is more than twice as long at Vostok than at Camp Century. This is not strictly an ice core feature and cannot be discussed further here (see below) as the Camp Century timescale is deduced from a comparison with the deep-sea record⁹. This shows the difficulty of applying such an indirect dating method.

Comparison with $\delta^{18}\text{O}$ in deep-sea cores

It is now widely accepted that $\delta^{18}\text{O}$ in benthic foraminifera primarily reflects ice-volume changes^{3,45,46}. Although the relationship can be distorted by many factors, the CLIMAP project members concluded that there is no compelling evidence to reject the first-order assumptions of isotope synchronicity or fidelity to the ice volume⁴⁵. Although varying in detail, all the cores give similar general trends^{3,47}, allowing a common definition of isotope stratigraphy. The period of interest here covers Emiliani's stages 1–6 (ref. 48), stage 5 being subdivided in 5a to 5e (ref. 49), as we have illustrated on Fig. 4e.

With the adopted Vostok dating, there is a good correspondence between stages 1–4 and Vostok stages A–D. Stage E covers 5a–5c and F corresponds to 5d. However, there is no clear correspondence between 5e and G representing the last interglacial in deep-sea and ice records, respectively (Fig. 4). There is a major difference in the duration of these two stages; 11 kyr for 5e and 24 kyr for G. Also, the last interglacial peak in the Vostok core is around 130 kyr BP whereas the corresponding ice-volume minimum in the deep-sea record is dated earlier at 122-kyr BP (ref. 45).

A doubling of the accumulation rate over this period would lead to a good correspondence between the 5e and G stages. While this possibility cannot be completely ruled out, there is no indication of such a drastic change in the precipitation regime. Part of the time-lag between the two peaks could be real (~ 3 kyr) as already observed between Southern Hemisphere ocean temperature and ice volume records but dating uncertainties (probably of ~ 10 kyr at this level) prevent a detailed discussion of this possible lag. On the other hand, the fact that ice stage G probably lasted longer than stage 5e is a key element for understanding the last interglacial climate and the initiation of the last ice age. A detailed interpretation is beyond the scope of the present study and would require knowledge of the exact timing between the temperature and ice volume signals. Recent measurements of $\delta^{18}\text{O}$ of air entrapped in ice cores could provide a way of correlating deep-sea and ice-cores $\delta^{18}\text{O}$ profiles and then establishing this timing⁵⁰.

Fig. 4 Variation with time of: a, winter, summer and annual insolation at 80° S (ref. 59); b, $\delta^{18}\text{O}$ in the Vostok ice (this work); c, $\Delta\delta^{13}\text{C}$ in the V 19-30 deep-sea core⁶⁸ and indication of the CO_2 scale on the right; d, summer insolation at 65° N (ref. 59); e, $\delta^{18}\text{O}$ in the V 19-30 deep-sea core⁶⁸ for *Uvigerina Senticosa* with an indication of the successive climatic stages.

According to CLIMAP members⁴⁵, the last interglacial was similar to the current climate. However, they noted some indications of a slightly warmer climate. The Vostok record brings quantifiable evidence of atmospheric warming over Antarctica during this period. This is useful information because there is some controversy about the behaviour of the East Antarctic ice sheet during the last interglacial⁴⁵. In addition, the Vostok record does not support an interglacial character for marine stage 5c (first part of E), an argument used to suggest an East Antarctic ice surge around 95 kyr BP (ref. 51).

Whereas glacial buildups in the deep-sea record (Fig. 4e) are gradual giving the ice-volume cycles their asymmetrical saw-toothed character⁵², the ice record (Fig. 4b) shows that the minimum temperatures were of the same order during cold periods (H, F, D and B stages). This may be linked to the rapid response of the atmospheric system to forcings and feedbacks and also suggests that there is a very stable mode of the climatic system for these cold periods. Such differences in shape were previously noted between ice-volume and temperature signals recorded in some oceanic cores⁵³.

Forcing and feedback factors

Beyond this reconstruction of the East Antarctic climate, we now discuss some current important aspects of the mechanisms which have probably controlled this climate and how the East Antarctic climate is related to the global climate. We will examine the possible role of changes in insolation, atmospheric CO_2 content and global ice volume.

Insolation changes. Over recent years, the Milankovitch hypothesis that orbital variations are the principal causes of the Pleistocene ice ages has received considerable support^{45,52-54}, and has stimulated many modelling efforts⁵⁵⁻⁵⁸. The spectral analysis of proxy records has revealed periodicities statistically correlated to the precessional (19 and 23 kyr), obliquity (41 kyr) and eccentricity (100 kyr) cycles. There is a general consensus

that summer insolation at about 65° N might be a plausible forcing as Northern Hemisphere ice sheets have undergone the major changes, and that the dominant 100-kyr cycle would result from a nonlinear response of ice sheets to orbital forcing.

Before discussing the possible link between the Northern Hemisphere insolation changes and the Vostok climate, we will investigate whether there is a relationship between this climate and the local changes of insolation.

The comparison of the $\delta^{18}\text{O}$ ice profile (Fig. 4b) with the annual insolation curve for 80° S (ref. 59) (Fig. 4a) reveals a very striking relationship between the cold and warm isotope stages and the minima and maxima of the insolation curve. While discontinuous sampling prevents us from performing reliable spectral analysis, especially for short periodicities, this remarkable correlation strongly supports the role of orbital forcing in climatic change.

The particular importance of the obliquity cycle, previously suggested from some high-latitude oceanic cores⁵⁴, would indicate that orbital forcing acts at a local scale. At 80° S, the maximum change of annual insolation is ~7% (ref. 59) which, from the radiative equilibrium equation, corresponds to a direct temperature effect of 4 °C. This direct effect is certainly important when compared with the 10 °C temperature range inferred from the $\delta^{18}\text{O}$ profile.

The apparent climatic synchronicity between the Northern and Southern Hemispheres poses a problem because the seasonality history of the polar insolation at 65° is 'different' for the two hemispheres^{60,61}. One explanation⁶¹ could be that, for polar regions, the climate responds to annual insolation changes that are in phase for the two hemispheres. The correlation between the 80° S annual insolation and the $\delta^{18}\text{O}$ record gives some support to this hypothesis.

Finally, accepting the role of orbital forcing on the Southern Hemisphere climate, the existence of a roughly 40-kyr cycle in the $\delta^{18}\text{O}$ ice core record indirectly supports the Vostok core dating.

Atmospheric CO_2 concentration. CO_2 measurements from the analysis of air bubbles entrapped in ice from Greenland and Antarctic cores have shown that CO_2 changes are associated with climatic changes. Such direct measurements are available for the past 40 kyr (refs 62-65) and show a CO_2 increase of ~40% between the last glacial maximum and the pre-industrial Holocene period. These measurements suggest that CO_2 and its greenhouse warming might be involved in the control of the ice ages²¹ and also in their interhemispheric synchronicity^{42,60}.

Shackleton *et al.*⁶⁶ have used the idea that the difference in carbon isotope ratios in surface and deep oceanic waters varies with CO_2 levels⁶⁷ to develop an indirect approach which extends the atmospheric CO_2 record further back in time. They estimate this parameter from the $\delta^{13}\text{C}$ difference between planktonic and benthic foraminifera ($\Delta\delta^{13}\text{C}$). The validity of this approach is supported by the fact that the estimated CO_2 values are consistent with the polar record over their common part⁶⁶ (the past 40 kyr). However, because many assumptions underlie this method, it has to be corroborated either from other oceanic cores or, more directly, from ice cores. A study is in progress to obtain a detailed CO_2 profile along the Vostok core to examine directly the CO_2 -climate connection over the past 150 kyr. In the following discussion, we will treat the $\Delta\delta^{13}\text{C}$ curve as a CO_2 curve.

The first 150 kyr of this $\Delta\delta^{13}\text{C}$ record⁶⁸ is shown on Fig. 4c. One can easily see the similarities between this curve and the $\delta^{18}\text{O}$ Vostok record. A relationship between CO_2 content and atmospheric temperatures is expected. Indeed, climate models predict that the greenhouse CO_2 effect should be amplified in high latitudes especially near ice margins^{69,70}. Thus, these observed similarities suggest a CO_2 -atmospheric temperature connection all over the last climatic cycle. According to Stauffer *et al.*²¹ a 40% CO_2 change corresponds to a temperature rise of 2-4.5 °C in high latitudes. Thus, the hypothesis that CO_2 changes are an important factor in controlling high latitude climate is well within the realm of possibility.

There are several other features of the CO₂-climate relationship. CO₂ measurements at Dome C indicate that the increase in CO₂ concentration associated with the end of the last ice age began before, or simultaneously with, the climatic change at high southern latitudes⁶⁵. On the other hand, from the 340-kyr reconstructed CO₂ curve, Pisias and Shackleton⁷¹ inferred that CO₂ lags the orbital forcing (summer insolation at 65° N) but leads the ice volume, by an average of 2.5 kyr. From this, they made two important points^{68,71}: (1) CO₂ changes are not a consequence of climatic changes but may represent part of the mechanisms by which orbital variations induce changes in climate; (2) the presence of a strong obliquity component suggests a high-latitude control for the mechanisms by which CO₂ responds to orbital forcing.

This also puts constraints on the way in which CO₂ levels in the ocean surface, which eventually control the atmospheric CO₂ levels, can vary⁶⁸. Recently, four groups⁷²⁻⁷⁵ have independently explored CO₂ scenarios implying a high latitude control through: the changes in ocean circulation; the influence of the amount of light reaching the polar regions on the utilization of nutrients; and a combination of these two factors.

The Knox and McElroy nutrient scenario⁷⁴ includes a mechanism whereby small changes in insolation at high latitudes could result in large changes in CO₂ and thus looks attractive in view of the possible CO₂ climatic role at the timescale considered here although this type of scenario⁷⁸ is not supported by recent results on planktonic foraminifera from Antarctic deep-sea sediments.

Ice-volume feedbacks. Although many assumptions are involved, the above discussion suggests that local insolation and possibly the atmospheric CO₂ have played a part in determining the Antarctic climate over the past 150 kyr. The two factors alone, however, would not explain all the climatic variability seen in the $\delta^{18}\text{O}$ Vostok record. In particular, we observe that the very cold stage F corresponds to an intermediate inferred CO₂ value.

Note that this stage F corresponds to the time of lowest insolation at 65° N (Fig. 4d)⁵⁹. (Indeed, there are similarities between this insolation curve and the $\delta^{18}\text{O}$ Vostok record (Fig. 4b) over all the past 150 kyr.) Modelling of the growth and retreat of the ice sheets has shown that ice volume changes can be driven by summer radiation in Northern Hemisphere high latitudes^{56,57,76,77}. Although all of the models do not specifically refer to 65° N, the generated ice-volume curves resemble, with a few kiloyears lag, the summer insolation at this latitudinal band. As shown in Fig. 4d, high volumes correspond to low insulations and vice versa. Such generated ice volume curves differ from ice volumes deduced from benthic foraminifera (Fig. 4e). In particular, note the difference during stage F. According to Budd⁶¹ the two approaches of deriving ice volumes can be reconciled if the contribution of ^{18}O -poor Antarctic ice is taken into account. This raises the question of how Northern Hemisphere ice extent can influence Antarctic climate.

Although we cannot answer this question here, we note that recent GCM results⁴² show that such a relationship cannot be explained by the interhemispheric exchange of heat in the atmosphere. Other mechanisms would have to be involved, such as a change in the cross-equatorial heat transport by the ocean circulation^{42,60,78} or a response of the East Antarctic ice sheets to sea-level changes⁶¹. This second hypothesis is valid only if its apparent contradiction with the time lead of Antarctic sea-ice compared with the Northern Hemisphere ice volume can be solved as suggested by Budd⁶¹.

Conclusions

We have obtained the first complete and unambiguous isotope description from a deep-ice core of the last climatic cycle. The 2,083-m Vostok record covers the past 150 kyr extending into the end of the previous glacial period. The timescale has been established by combining a glaciological model appropriate here as the core represents only about the first half of the ice sheet, with an original approach for estimating past accumulation rates from the isotope record. While this method has its own limita-

tions, it has the advantage of being independent of other palaeo-indicators or climatic forcing series.

This $\delta^{18}\text{O}$ record has been interpreted as essentially representing temperature changes over East Antarctica. This interpretation is based on the $\delta^{18}\text{O}$ -temperature gradient observed for modern precipitation and on a dynamically-simple isotope model. Although aware of the necessity of a more detailed modelling of the atmospheric $\delta^{18}\text{O}$ cycle using GCMs, we have confidence in the temperature interpretation as far as major $\delta^{18}\text{O}$ changes are concerned.

In this interpretation, the Vostok record provides extremely rich climatic information. The present Holocene period was preceded by a long glacial period marked by two relatively warm interstadials. The well-marked last interglacial was significantly warmer than the Holocene and the end of the previous glacial was quite similar to the last glacial maximum.

A comparison with $\delta^{18}\text{O}$ in deep-sea cores shows that the Antarctic climate and the global ice volume have not evolved in the same way. The last interglacial appears to be about twice as long in the Antarctic temperature record as in the ice-volume record. In addition, there are marked differences in the shapes of the records during the last glacial. Thus, we now have access to another different, but complementary, climatic record fully covering the last climatic cycle.

The presence of a roughly 40-kyr cycle in the Vostok record strongly supports the role of orbital forcing in determining climatic changes. This record is approximately in phase with the annual insolation at 80° S suggesting that this forcing operates at a local scale. There are also some common features between the climatic curve and the summer insolation at 65° N which may be the result of the influence of the Northern Hemisphere ice sheets on the Antarctic climate.

There are striking similarities between the $\Delta\delta^{13}\text{C}$ curve of Shackleton and co-workers^{66,68} and the $\delta^{18}\text{O}$ record. Following these authors in treating the $\Delta\delta^{13}\text{C}$ curve as a CO₂ curve, there appears to be, over a complete climatic cycle, a relationship between atmospheric CO₂ levels and atmospheric temperatures as previously suggested for the past 40 kyr.

There are several other ways to obtain more climatic information from the Vostok ice than the $\delta^{18}\text{O}$ method described here. Interesting results concerning ^{10}Be have been obtained²⁷, and other studies are either in progress or planned for the near future. They include additional deuterium and oxygen-18 determinations and measurements of total gas volume, crystal size, CO₂ in the air bubbles, $^{18}\text{O}/^{16}\text{O}$ ratio of oxygen in air and aerosol content.

The Vostok ice core offers the possibility of measuring many other parameters and their variation with time. As shown from other ice cores, the number of these parameters of interest is growing. Recent studies include more and more chemical elements⁷⁹⁻⁸³ and trace gases⁸⁴ as well as $^{12}\text{C}/^{13}\text{C}$ ratio in CO₂ (ref. 85). Although their first objective is to reconstruct the Earth's palaeo-environment, some of these parameters also contain, at least indirectly, palaeoclimatic information. Finally, it is hoped to reach greater depths in the Vostok drilling and thus to extend the time scale considerably.

We are very grateful to all Soviet and French participants in drilling, field work and ice sampling which was prepared, in particular, by K. V. Blinov. We thank G. Mondet for isotopic determinations. We also thank W. F. Budd, R. Sadourny, N. J. Shackleton for helpful discussions. The presentation of the work has largely benefited from very constructive criticisms of J. C. Duplessy, G. Raisbeck, D. Raynaud, J. White, and F. Yiou. This work was supported in France by the EPF (Expéditions Polaires Françaises), PNEDC (Programme National d'Etudes de la Dynamique du Climat) and TAAF (Terres Australes et Antarctiques Françaises) and in USSR and Vostok by Soviet Antarctic Expeditions.

A phage repressor-operator complex at 7 Å resolution

John E. Anderson, Mark Ptashne & Stephen C. Harrison

Department of Biochemistry and Molecular Biology, Harvard University, 7 Divinity Avenue, Cambridge, Massachusetts 02138, USA

The crystal structure of a complex between the DNA-binding domain of phage 434 repressor and a synthetic 434 operator shows that the protein, very similar in conformation to λ repressor, binds to B-form DNA with the second α-helix of a helix-turn-helix motif lying in the major groove.

WE present the X-ray crystal structure at 7 Å resolution of a repressor protein bound to its operator DNA. The protein (also a positive regulator of gene expression) is the amino-terminal, DNA-binding domain of the repressor encoded by coliphage 434, a close relative of phage λ. The operator is a 14-base-pair (bp) synthetic oligonucleotide with 2-fold symmetry that is specifically recognized by 434 repressor. Determination of the structure was facilitated by the preparation of isomorphous repressor-DNA crystals using operator DNA with 5-bromodeoxyuridine instead of thymine at two symmetry-related positions. Important aspects of the structure include: (1) The repressor conformation, predominantly α-helical, is remarkably similar to that of the first four α-helices of λ repressor¹. (2) The DNA conformation is B-like, with some deviation at the ends of the operator. (3) Repressor contacts the DNA backbone at several distinct points. Bushman *et al.*² elsewhere in this issue present evidence that these are sites of strong interaction between repressor and DNA phosphates. (4) An α-helix (α3) lies in the

major groove of the DNA and another α-helix (α2) lies across the groove. The helices α2 and α3 correspond to the helix-turn-helix motif found in the crystal structures of three other DNA-binding proteins^{1,3,4} (and postulated to occur in many more, including 434 repressor⁵⁻⁷). The mode of binding to DNA is similar to that proposed for those proteins on the basis of model building^{1,8-10,22}, with the α3 helix disposed so that its residues can make sequence-specific contacts with DNA. Changing these residues in the α3 helix of 434 repressor can change the specificity of the repressor (ref. 11 and accompanying paper¹²).

Structure determination

Crystals of the complex of the 434 repressor DNA-binding domain R1-69 and synthetic 434 operator DNA were prepared as described previously¹³. The space group is I422, with $a = b = 166.4$ Å, $c = 139.4$ Å. Each strand of the synthetic DNA operator had the sequence 5'HO-d(A-C-A-A-T-A-T-A-T-A-T-T-G-T)-OH 3'. Derivative crystals were also prepared, using a similar

Fig. 1 Noncrystallographic Harker section. *a*, The section of the difference Patterson that lies 45.6 Å from the origin and perpendicular to the body diagonal of the unit cell. The body diagonal intersects the section at its centre. The small squares of the grid are 5 Å on a side. The set of six peaks corresponding to vectors between equivalent Br atoms on adjacent 14mers forms a roughly hexagonal array, with each peak lying ~18 Å from the body diagonal. Peaks from analogous Br atoms on straight B-DNA with its helix axis coincident with the body diagonal would lie 9.5 Å from the centre. *b*, The same section after 3-fold averaging about the body diagonal, using the programs of Bricogne¹⁸.

oligonucleotide with 5-bromodeoxyuridine instead of dT at position 7. (Both 14mers were purchased from Pharmacia P-L Biochemicals.) Data were collected to 7 Å resolution using a Xenonics imaging proportional counter¹⁴ with CuK α radiation from an Elliott GX-6 rotating anode X-ray generator. Integrated intensities were obtained as described by Durbin *et al.*¹⁴ and processed using programs from P. R. Evans (MRC Laboratory of Molecular Biology, Cambridge, UK). Combination statistics are shown in Table 1. The mean isomorphous difference was

Table 1 Data combination statistics

	R_{sym}	N	$\bar{I}$
Native	0.087	1,171	270
Br	0.066	1,134	455

N , number of measurements; $\bar{I}$, mean intensity; $R_{\text{sym}} = \sum_h |I_h - \bar{I}_h| / \sum_h I_h$.

small (0.12 for 1,105 common reflections). The consequent noisy difference Patterson could not be interpreted directly, but the positions of the Br atoms were obtained by a procedure that took advantage of the previously described analysis of packing in these crystals¹³.

Protein-DNA complexes in the I422 crystals are stacked in rods with noncrystallographic 3₁ symmetry, parallel to the body diagonals of the unit cell. The rise per repeat of the 3₁ axis is 45.6 Å, so that the section of the difference Patterson perpendicular to the body diagonal and intersecting it 45.6 Å from the origin is a 'noncrystallographic Harker section', in the sense that it contains peaks representing vectors between atoms related by the noncrystallographic symmetry. On this section of the Patterson, we therefore expected to find a set of 3-fold-related peaks corresponding to vectors between Br atoms on different 14mers. Moreover, the known chemical structure of the derivative restricted the range of possible distances of these peaks from the noncrystallographic symmetry axis. Figure 1 shows the pattern actually found, before and after 3-fold averaging. It is similar to the pattern expected on the basis of the packing model of Anderson *et al.*¹³, in which the DNA is stacked end-to-end in straight rods parallel to the unit cell body diagonals, but the peaks are ~5 Å farther from the axis than predicted. We found that B-DNA with a slight right-handed supertwist placed Br atoms in positions that matched the observed pattern much better. The local tilt of the DNA in this model was 12°.

Assignment of the Br-Br vectors on the noncrystallographic Harker section gives coordinates of the Br positions relative to the 3₁ axis, but leaves undetermined one translational degree of freedom, the displacement of this noncrystallographic symmetry axis from the body diagonal of the unit cell. There is also one origin ambiguity (see Fig. 2). The ambiguity was resolved,

and the translational displacement determined, using a search procedure in which calculated Br contributions and centric $[F_{\text{der}} - F_{\text{nat}}]$ were compared (by means of a correlation function) between 15 and 7 Å resolution. The details will be reported elsewhere (J.E.A., J. Moulai and S.C.H., in preparation). A peak in the correlation function gave a trial solution, which was refined by conventional methods¹⁵ (Table 2).

Native phases were determined and used to compute an initial electron-density map, which was inspected on an Evans and Sutherland PS300 interactive graphics system using the program FRODO (ref. 16). The map was noisy and contained no easily recognizable features, but averaging with respect to the noncrystallographic 3₁ axis gave some indication of a double-helical DNA backbone and several rod-like features where protein was expected.

Phases were refined by exploiting the redundancy of information present in the noncrystallographic 3₁ symmetry^{17,18}. In drawing the envelope required for phase refinement^{17,18}, it proved helpful to use a model map that included the N-terminal domain of λ repressor¹ and DNA as a guide. The model consisted of the coordinates of λ -repressor residues 17-85 (ref. 1) (to match the size of R1-69), positioned to fit a straight double helix of DNA aligned along the noncrystallographic 3₁, and, instead of straight DNA, the coordinates of the supertwisted

Table 2 Br atom position refinement

Statistics were calculated after 10 cycles of phasing and refinement¹⁵, using I422 data expanded to space group I222, starting with the positions calculated from model B-DNA with a right-handed supertwist ($\alpha = -12^\circ$; ref. 21) of the C-7 atoms of the thymine in position 7 of the 14mer sequence. m , Figure of merit; f_{rms} , root-mean-square heavy atom structure factor; E_{rms} , root mean square lack of closure error; $R_K = \sum |F_{\text{PH}}^{\text{obs}} - F_{\text{PH}}^{\text{calc}}| / \sum |F_{\text{PH}}^{\text{obs}}|$.

Fig. 2 Schematic projections down the 4-fold axis c (squares) of two of the four rods most closely associated with a lattice point, showing the two possible choices of origin (alternatives 1 and 2). The translational displacement, Δl (one of the parameters searched as described in the text) is shown for each. In alternative 1, the dyad between two Br atoms (filled circles) is coincident with the diagonal crystallographic dyad [110] (dotted line). In alternative 2, the dyad between two operators (rectangles) is coincident with the crystallographic dyad.

DNA used to locate the Br atom positions, with its superhelix axis coincident with the noncrystallographic symmetry axis. Inspection of the electron density computed from 7 Å structure factors of this model helped us to recognize features of the averaged initial map around which to draw the envelope. A total of six cycles of phase refinement were performed. The statistics are shown in Table 3 and part of the final map in Fig. 3. The positions of Br atoms are shown as stippled spheres in Fig. 3. Ribbons of density corresponding to double-helical DNA backbone are clearly visible, and it is easy to distinguish major and minor grooves. Rod-like density features (clearly low-resolution α -helices) are also visible next to the DNA on the opposite side from the Br atoms. One of these lies in the major groove of the DNA, and another is roughly at right angles to it. Their size and relative orientation show that they correspond to the helix-turn-helix motif seen in λ repressor¹, λ cro² and catabolite gene activator protein⁴, and their position on the operator is consistent with modes of binding suggested for those proteins by model building^{1,8-10,22}.

Structure of R1-69

A backbone model for λ repressor¹ can be superimposed on the electron-density map of the co-crystal in such a way that $\alpha 2$ and $\alpha 3$ (the helix-turn-helix motif) are well aligned in rod-like density features (Fig. 4). Inspection shows that two other 'sausages' of density correspond closely to the $\alpha 1$ and $\alpha 4$ helices of λ repressor. The axis of the $\alpha 1$ density is displaced from the axis of the λ -repressor $\alpha 1$ helix by 2–3 Å, and its orientation is slightly different. The N-terminus of 434 repressor $\alpha 1$ density is close to the C-terminus of $\alpha 3$ density, and com-

parison with the λ repressor model suggests that it corresponds to the N-terminus of the polypeptide chain. The fit of the λ -repressor $\alpha 4$ helix to the co-crystal density is even closer than that of $\alpha 1$, although not quite as good as $\alpha 2$ and $\alpha 3$. The final helix of the λ -repressor domain ($\alpha 5$, not shown in Fig. 4) does not lie in clearly rod-like density, suggesting that the fold of the 434 repressor polypeptide chain differs significantly from the λ -repressor fold in this region. The λ -repressor helix $\alpha 5$ mediates a close dimer contact between N-terminal domains. Such a close contact may indeed not occur in 434 repressor, because in the absence of DNA, R1-69 crystallizes as a monomer. (The space group of the R1-69 crystals is $P2_12_12_1$, with one protein molecule per asymmetric unit; S. Almo, J.E.A. and S.C.H., unpublished data.) The links between helices are not very clear in the co-crystal map (only the $\alpha 2$ and $\alpha 3$ 'sausages' are bridged by density at the level we chose to contour), but the correspondence between the λ -repressor model and rod-like density features makes us confident that we have correctly determined connectivity and chain direction. We conclude that R1-69 has a conformation very similar to that of the DNA-binding domain of λ repressor. It contains at least four α -helices, and their orientation and packing are similar in the two structures. The 434 repressor lacks the N-terminal arm of λ repressor, and the C-terminal portion of the domain may follow a different course.

Operator structure

Only the DNA backbone is clearly delineated at this resolution; density corresponding to base pairs is less regular. Ribbons of density follow fairly closely the path of the backbone of 10.5 bp per turn of B-DNA (Fig. 3), with a deviation of 2–3 Å towards the 3' ends of each strand which is described below. The positions of the Br atoms indicate that the local axis of the DNA is displaced by a few ångströms from the noncrystallographic 3_1 axis. In fitting the Br positions, we used a smooth supercoil with precise stacking of base pairs at the ends of adjacent 14mers, but the map suggests that a better fit can be obtained with a straight B-DNA model for each 14mer, tilted at $\sim 12^\circ$ with respect to the 3_1 and displaced from it by 4–5 Å, so that the register of the double helix is not maintained from 14mer to 14mer. This model produces nearly perfect overlap of the purine rings of the 5' adenine bases from successive 14mers; the 3' thymines are left unstacked. This exposure may in part account for the deviation of the 3' end of the backbone density from the B-DNA model, and a contact with an R1-69 monomer bound to the adjacent 14mer may also be involved (see below). A perturbation of strict B-DNA structure to fit the density involves a displacement of the 3' end of the 14-base strand by 2–3 Å (Fig. 5). As the 5' end of the opposite strand is not correspondingly displaced, some distortion of normal base-pair geometry may be required to accommodate the backbone shift. The shift seems significant only for the four 3'-terminal bases.

Protein-DNA contacts

As shown in Figs 3, 4 and 5, R1-69 is bound to DNA with $\alpha 3$ inserted in the major groove, a feature anticipated by previous models of repressor-DNA interaction^{1,3,4,8-10,22}. The axis of $\alpha 3$ is displaced by ~ 2 Å from the centre of the major groove. The position of the helix with respect to the base pairs seems to be determined by a set of contacts that the repressor domain makes with the DNA sugar-phosphate backbone (Fig. 5). One of these contacts is near the N-terminus of $\alpha 4$, where a strong bridge connects protein and DNA densities near the position of the phosphate 5' to base +10. (For the numbering of phosphate groups, see Fig. 5.) A less striking bridge occurs near the adjacent phosphate, 5' to base +9. Another strong bridge joins density from the N-terminus of $\alpha 2$ to density from the DNA backbone of the adjacent 14mer, near the phosphate between the two bases at the 3' end of the strand. In phosphate ethylation interference experiments using the 14mer sequence embedded in continuous DNA, Bushman *et al.*² infer that corresponding phosphates are contacted by intact repressor in solution. Ethylation

Table 3 Noncrystallographic symmetry phase refinement¹⁸

Overall phase change			68.9°

$$R = \sum |F_{\text{obs}} - F_{\text{calc}}| / \sum |F_{\text{obs}}|; \text{ mean phase change} = \sum |\phi_{\text{calc}} - \phi_{\text{obs}}| / N;$$

$$r = \frac{\sum |F_{\text{obs}}| |F_{\text{calc}}| - \sum |F_{\text{obs}}| \sum |F_{\text{calc}}|}{[\sum |F_{\text{obs}}|^2 - (\sum |F_{\text{obs}}|)^2][\sum |F_{\text{calc}}|^2 - (\sum |F_{\text{calc}}|)^2]}.$$

Fig. 3 *a*, Overview of the co-crystal map at 7 Å resolution after six cycles of noncrystallographic symmetry averaging and phase refinement. Almost an entire I422 asymmetric unit, consisting of three R1-69 monomers and one-and-a-half 14mers, is shown. Each protein-DNA complex consists of two protein monomers and one operator. The view is perpendicular both to the noncrystallographic 3_1 and to the dyad of a complex. The positions of Br atoms are shown as stippled spheres. Model B-DNA, tilted and displaced as described in the text, is superimposed on DNA electron density. *b*, Schematic representation of *a*, with α -helices (cylinders) labelled near their N-termini.

Fig. 4 Structure of R1-69. Straight B-DNA (red) and the α -carbon backbone of λ -repressor residues 17-75 (ref. 1) (gold), including the C-terminal half of $\alpha 1$ and all of $\alpha 2$ - $\alpha 4$, are superimposed on the electron density (see text). *a*, View perpendicular to the noncrystallographic symmetry axis of part of a monomer of R1-69 (the lower one of the dimer in Fig. 3). Helix $\alpha 3$ lies in the major groove of the DNA and $\alpha 2$ lies across $\alpha 3$. A strong bridge of density connects the N-terminus of $\alpha 2$ to the DNA backbone near phosphate +14 (see Fig. 5*b* for phosphate numbering) of the adjacent 14mer. At the top, bridges between protein and DNA are partially visible near phosphates +9 and +10. *b*, View in the same orientation as *a*, but farther from the DNA, showing helices $\alpha 1$ (lower right) and $\alpha 4$ (upper left). Helices $\alpha 2$ and $\alpha 3$ are visible in the background. *c*, Schematic representation of *b*, with the α -helices (cylinders) labelled near their N-termini.

Fig. 5 Protein-DNA backbone contacts. **a**, Schematic drawing showing the contacts. The helix-turn-helix structures and part of the protein backbone just C-terminal to $\alpha 3$ are shown for a dimer of R1-69. The diagram includes one entire 14mer and the ends of the adjacent 14mers, drawn as straight B-DNA. The tilt of the adjacent 14mers is slightly exaggerated. Filled circles indicate positions where the locations of contacts between protein and DNA phosphates suggested by the crystal structure and those inferred from ethylation interference experiments² agree. Dotted lines connect the phosphates to the regions of the protein believed to provide the contacts. The part of the protein responsible for the phosphate contact nearest the centre of the operator is not known. The arrows show the directions of the displacements seen in the crystal of the 3' ends of the DNA strands of the adjacent 14mers (see text). These displacements result in part from contacts made by the N-termini of the $\alpha 2$ helices of the dimer bound to the central 14mer. The corresponding displacements of the 3' ends of the strands of the central 14mer, resulting from proteins bound to the adjacent 14mers, are not shown. **b**, The DNA sequence corresponding to **a**, showing the positions of possible contact between protein and DNA suggested by the crystal structure, and giving the phosphate numbering scheme used in the text. Bases belonging to the same 14mer are connected by small dots. The large dot in the centre locates the 2-fold axis of the central 14mer. Triangles, contacts made by the R1-69 dimer associated with the central DNA 14mer; circles, contacts made by proteins bound to the flanking 14mers. Filled symbols have the same meaning as in **a**; open symbols indicate positions where a contact is suggested by the crystal structure but not detected by ethylation interference².

of the phosphates 5' to bases -1 (the first base outside the 14mer sequence), +9 or +10 on either strand interferes strongly with repressor binding. We believe that the -1 phosphate contact corresponds to the contact in the crystal between $\alpha 2$ and the adjacent 14mer, and that the other two correspond to the bridges of density in the centre of the operator. These results show that the overall configuration of the complex of intact repressor with DNA is similar to that of R1-69, although it is possible that the details of the interactions are slightly different because of constraints imposed by stable dimerization of the intact molecule.

Strictly speaking, confluences of protein and DNA densities such as those just described imply nothing more than close proximity, but it is reasonable to suppose that a bond will form

if the appropriate type of residue is nearby. Groups most likely to interact directly with negatively charged DNA phosphates are those that are positively charged and those that can donate hydrogen bonds. Our confidence that we have correctly identified helices and their connectivity, and how they relate to the amino-acid sequence, permits us to enumerate amino-acid residues that could be involved in these interactions. We suggest that Asn 16 or Gln 17 (or both) might participate in the contact at the N-terminus of $\alpha 2$, Lys 40, Arg 41, or Arg 43 could be involved in the +9 and +10 contacts; some residue C-terminal to $\alpha 4$ might also contact the +9 phosphate. We also note that helices $\alpha 2$, $\alpha 3$ and $\alpha 4$ are arranged so that the N-termini of all three point towards DNA phosphates. The N-terminus of an α -helix carries a virtual partial positive charge¹⁹ which could produce favourable interactions with DNA phosphates to stabilize binding in the observed orientation. A role for interactions between the N-terminal ends of α -helices and backbone phosphates in the binding of λ repressor to DNA has been suggested previously¹.

With the relationship between protein and DNA in our interpretation of the electron density, it is not possible for Asn 16 or Gln 17 to hydrogen bond to the -1 phosphate if the operator is embedded in continuous, straight DNA. If the continuous DNA is given a slight super-twist, however, then both residues are brought to within reasonable hydrogen-bonding distance of the phosphate². This suggests that if the ethylation interference at the -1 phosphate involves disruption of hydrogen bonds donated by Asn 16 or Gln 17, then the DNA is slightly bent (to a radius of curvature of ~ 100 Å) by repressor binding. A slight bend would also enhance any charge interaction that exists between the N-terminus of $\alpha 2$ (see above) and the -1 phosphate. Other deformations of the double helix are possible, but super-twisting (or bending) is the simplest and most easily interpretable. The displacement of 14mers from the noncrystallographic 3₁ axis, as well as the displacement of the 3' end of the DNA strand seen in the crystal (see above and Fig. 5a), may be related to this suggested tendency of repressor to bend DNA when it binds². A monomer of R1-69 bound to a particular 14mer in the crystal can make the $\alpha 2$ contact (which we propose is made to the -1 phosphate on bent continuous DNA in solution) only by lateral displacement of the neighbouring 14mer. The consequently unstacked 3' end of this neighbour might then adjust further to optimize contact with the N-terminus of $\alpha 2$.

There are two other interactions between protein and DNA backbone suggested by our interpretation of the electron density. The N-terminus of $\alpha 3$ closely approaches the DNA backbone, placing the side chain of Ser 30 in a position to hydrogen bond to the phosphate 5' to base +11. Ethylation at that phosphate decreases binding, although less strongly than the modifications described above². Finally, just beyond the C-terminus of $\alpha 3$, an arm of density reaches towards the opposite DNA strand near the phosphate 5' to base +3. The location and orientation of the arm suggest a salt bridge between that phosphate and the side chain of Lys 38, but ethylation at that position has little effect on binding².

Side chains on the external surface of $\alpha 3$ (those that would be exposed to the solvent if not in the complex) are clearly in position to make sequence-specific contacts to the bases in the major groove. The excellent fit of the λ -repressor backbone and of B-DNA to features of the electron density, the invariance in three other structures of the helix-turn-helix motif^{5,20}, and the assignment by sequence similarity of corresponding residues in the λ and 434 repressors^{6,7} permit limited model building of specific interactions between protein and DNA by insertion of 434 repressor side chains onto λ -repressor backbone positioned as in Fig. 5. An important preliminary conclusion is that base pairs 1-4 seem to be accessible to direct interaction with repressor side chains on the $\alpha 3$ helix, with contacts possible between Gln 28 and base pair 1, Gln 29 and base pairs 2 and 3, and Gln 33 and base pairs 3 and 4. In addition, residues in the turn between $\alpha 3$ and $\alpha 4$ can probably contact base pair 5

and possibly base pair 6. We are attempting to test these suggestions and are extending the resolution of the structure determination to 3.2 Å.

Changing the binding specificity of a repressor by redesigning an α -helix

Robin P. Wharton & Mark Ptashne

Department of Biochemistry and Molecular Biology, Harvard University, 7 Divinity Avenue, Cambridge, Massachusetts 02138, USA

We replaced amino acids on the 'outside', or solvent-exposed, surface of the DNA recognition α -helix of 434 repressor with the corresponding amino acids from the recognition helix of P22 repressor. The binding specificity of the resulting hybrid protein, as measured in vivo and in vitro, was that of P22 repressor.

THE X-ray crystal structure of the bacteriophage 434 repressor bound to its DNA operator is described in the accompanying paper¹. One striking feature of the structure is that an α -helix of the protein ($\alpha 3$, or the recognition helix) lies in the major groove of the B-form operator DNA where it presumably makes sequence-specific contacts. This helix is part of a conserved 'helix-turn-helix' unit found in the structures of three other sequence-specific DNA-binding proteins (λ repressor, λ cro protein, and *Escherichia coli* catabolite gene activator protein (CAP))²⁻⁶. For each of these proteins, model building has suggested that the recognition helix can be placed in the major groove of the relevant operator⁷⁻⁹. The conserved helix-turn-helix unit has been predicted to exist in many other DNA-binding proteins based on amino-acid sequence homologies¹⁰⁻¹². Analyses of mutant proteins¹³⁻¹⁸ are consistent with the proposal that at least part of the specificity of binding is determined by the recognition helix in each of several cases.

In the experiments described here, we have redesigned the recognition helix of 434 repressor so that the resulting protein has a new biological activity. On the outside (solvent-exposed) surface of the α -helix, the redesigned 434 repressor bears amino acids that are presumed to lie at the corresponding positions on the recognition helix of a different repressor, that encoded by the *Salmonella* bacteriophage P22. Amino acids on the 'inside' surface of the helix were unchanged. We reasoned that this strategy would allow the new amino-acid sequence to fold into an α -helix in the context of the remainder of the protein. *In vivo*, the parental 434 repressor binds only to 434 operators, but the redesigned 434 hybrid repressor, named 434R [$\alpha 3$ (P22R)], binds only to P22 operators. *In vitro*, purified 434R [$\alpha 3$ (P22R)] binds specifically to P22 operator DNA. Furthermore, it binds to the three binding sites in wild-type P22 O_R with the same affinity order as does P22 repressor, namely $O_{R1} = O_{R2} > O_{R3}$. The apparent affinities of P22 repressor and 434R [$\alpha 3$ (P22R)] for P22 operator DNA are comparable. We conclude first, that in 434 repressor, amino acids along the recognition helix are solely responsible for distinguishing between binding to two different sets of operators; and second, 434 repressor and P22

repressor present their recognition helices in very similar ways to 434 operators and P22 operators, respectively.

Redesigning the recognition helix

The presumptive configurations of the recognition helices and flanking residues of the 434 and P22 repressors are shown in Fig. 1a. The arguments that led to the assignment of these particular configurations are summarized in Fig. 1 legend. To redesign 434 repressor, we assumed that residues on the inside surface of its helix, which pack against the body of the repressor, could not be substituted without destabilizing the protein. We also assumed that amino acids on the outside surface, which are free to interact with DNA in the protein-DNA complex, could be substituted without strongly affecting the stability of the protein. Figure 1b shows the presumptive configuration of the redesigned recognition helix and flanking residues of 434R [$\alpha 3$ (P22R)]. Compared with wild-type 434 repressor, 434R [$\alpha 3$ (P22R)] bears five amino-acid substitutions taken from P22 repressor.

Figure 1c shows the sequence of a fragment of the gene encoding 434R [$\alpha 3$ (P22R)], and, schematically, the strategy by which it was constructed. Using mismatched primer mutagenesis *in vitro*, we introduced restriction enzyme cleavage sites that bracket the region encoding the recognition helix in the 434 repressor gene. This region was then removed from the 434 repressor gene by cleavage with the appropriate restriction enzymes, and replaced with a new DNA sequence, constructed from four synthetic oligonucleotides, which encodes the hybrid helix of 434R [$\alpha 3$ (P22R)]. The hybrid gene was fused to the *lac* promoter to create the plasmid pRW219. When pRW219 was introduced into an appropriate *E. coli* strain, ~1% of cellular protein was 434R [$\alpha 3$ (P22R)] (data not shown).

434R [$\alpha 3$ (P22R)] activity *in vivo*

E. coli cells that are producing the repressor encoded by a particular phage are immune to infection by that phage. Because P22 is a *Salmonella* phage which does not grow in *E. coli* strains, hybrid phages named λimm^{434} and λimm^{P22} were used in the

Fig. 1 Redesigning the outside surface of the recognition helix of 434 repressor. *a*, Schematic representations of the presumptive recognition helices of the 434 and P22 repressors. *b*, Two schematic representations of the presumptive configuration of the recognition helix of 434R [$\alpha 3$ (P22R)]. *c*, Construction of the gene encoding 434R [$\alpha 3$ (P22R)]. *a*, The dispositions of amino acids were assigned by superimposing the conserved helix-turn-helix units predicted to exist in the 434 and P22 repressors¹⁰ on the helix-turn-helix unit seen in the X-ray crystal structure of λ repressor². We have previously presented results that support this disposition of amino acids in the recognition helix of 434 repressor¹³, and Anderson *et al.*¹ have recently demonstrated the existence in 434 repressor of a helix-turn-helix unit. The Gly residue, present at the turn in almost all predicted helix-turn-helix units¹⁵, is triply underlined for reference. The amino-acid sequence shown for P22 repressor is actually that of the *pcA* mutant P22 repressor³⁰, in which Lys replaces the Glu of wild-type P22 repressor at residue 42. Residue 42 is the underlined lysine in the following sequence in the figure: ... Ser-Lys-Thr-Glu ... No differences between the DNA-binding activities of wild-type P22 repressor and *pcA* mutant P22 repressor have been observed *in vivo*³⁰ or in an extensive series of measurements *in vitro* (J. Douhan III and M.P., unpublished data; see also Fig. 3). Therefore, in constructing the gene encoding 434R [$\alpha 3$ (P22R)], we chose not to change the residue at the corresponding position in 434 repressor, Lys 38. *b*, Amino acids taken from P22 repressor are drawn in white letters inside black boxes. The dashed lines at either end of the first drawing indicate that this helix is embedded in the remainder of the 434 repressor protein. The second representation³¹, a view from the carboxy-terminal end of the helix in projection down the helical axis, emphasizes the spatial segregation of P22 repressor-derived amino acids on the outside surface of the helix (white letters in black boxes) and 434 repressor-derived amino acids on the inside surface of the helix (black letters). Note that the amino-acid substitution at position -1 of the recognition helix is not present in this second representation and that the recognition helices of 434 repressor and P22 repressor have common amino acids at positions 4, 6 and 8. *c*, A portion of the gene encoding 434R [$\alpha 3$ (P22R)] is shown with the corresponding amino-acid sequence. The conserved glycine residue is again triply underlined for reference (see *a*). The five amino-acid substitutions in 434R [$\alpha 3$ (P22R)] are marked by arrows. DNA to the left of the *KpnI* site and to the right of the *DdeI* site encodes the 193 amino acids that are identical in 434 repressor and 434R [$\alpha 3$ (P22R)]. DNA between the *KpnI* and *DdeI* sites was assembled from four synthetic oligonucleotides which are represented by two white and two stippled boxes. Also shown are sites for the restriction enzymes *MboI* and *TaqI* which were used in the experiments described in Fig. 4. These sites are common to the genes encoding 434 repressor and 434R [$\alpha 3$ (P22R)].

Methods. A site for the enzyme *KpnI* was introduced into the gene encoding 434 repressor to create the plasmid pRW199. We used an oligonucleotide with the sequence: 5'-TGCTGGGTGTACCCACCTT-3' which was mismatched with bases in the wild-type gene at the two underlined nucleotides. Mutagenesis was performed as described previously¹³ using the methods of Zoller and Smith³² with the following exceptions: single-stranded DNA was prepared from the *dam*⁻ *E. coli* strain RW102 (our unpublished data), and the template DNA was a derivative of the plasmid, pEMBL8+ (ref. 33). The four synthetic oligonucleotides shown in *c* which encode part of 434R [$\alpha 3$ (P22R)] were assembled essentially as described by Sgarbetta and Khorana³⁴, and the resulting 39-bp duplex which had *KpnI*- and *DdeI*-compatible ends was isolated by gel electrophoresis. This DNA fragment was substituted for the corresponding 39-bp fragment of pRW199 essentially as described previously¹³.

Table 1 Immunity specificity of 434R [$\alpha 3$ (P22R)] *in vivo*

Protein	Immunity to	
	λimm^{434}	λimm^{P22}
434 R	+	-
P22 R	-	+
434 R [$\alpha 3$ (P22 R)]	-	+

Phages were spotted lawns of three host strains, each of which was producing one of the repressors listed in the column on the left. Following overnight incubation, the lawns were examined for evidence of plaque formation and host killing. + Indicates that host cells were immune to infection (no apparent cell lysis) and - indicates the converse. Identical results were obtained following overnight growth at either 30 or 37 °C. λimm^{434} and λimm^{P22} are hybrid phages in which the repressor gene and operators of phage λ are replaced by the repressor gene and operators of phages 434 and P22, respectively^{19,20}. These phages behave with regard to their immunity properties exactly as do the parental phages, 434 and P22^{19,20}. In all cases where phage growth occurred, phage spots were turbid except when λimm^{434} was spotted on cells producing 434R [$\alpha 3$ (P22R)]. Each of the three proteins in the table was at least 1% of cellular protein. The bacterial host strains for these experiments were derivatives of XA90 (ref. 26) which carried an F'(*lac*^{Q1}) episome²⁷ as well as the plasmids listed below. Spot tests were performed in the presence of 1 mM isopropyl β -D-thiogalactopyranoside (IPTG) to induce the synthesis of each of the repressors whose genes are transcribed by *lac* operon promoters. Listed below for each repressor is the name of the plasmid that was introduced into XA90 cells to direct synthesis of the protein, and the estimate of the percentage of total protein that consisted of repressor in these cells based on electrophoresis in SDS-polyacrylamide gels²⁸ of total cellular protein: 434 repressor, pRW88 (ref. 13), 1% (or pRW190, 10%, our unpublished data); P22 repressor, pTP15 (ref. 29), 1%; 434R [$\alpha 3$ (P22R)], pRW 219 (see Fig. 1), 1%.

experiments described below. In these hybrid phages, the repressor gene and operators of phage λ have been replaced by the repressor gene and operators of phages 434 and P22, respectively^{19,20}. *In vivo*, the DNA-binding activity of 434 repressor or P22 repressor is extremely specific: cells producing 434 repressor are immune to infection by λimm^{434} phages but not immune to infection by λimm^{P22} phages¹⁹, whereas cells producing P22 repressor are immune to infection only by λimm^{P22} phages²⁰. This binding specificity is maintained even when cells are producing very large quantities of either 434 or P22 repressor (see Table 1). (For reference, Fig. 2 shows consensus DNA sequences for 434 and P22 operators.)

To test the DNA-binding specificity of the hybrid repressor, 434R [$\alpha 3$ (P22R)], we spotted λimm^{434} phages and λimm^{P22} phages on a lawn of cells producing 434R [$\alpha 3$ (P22R)]. These cells were immune to infection by the λimm^{P22} phages and not immune to infection by the λimm^{434} phages (Table 1). The degree of immunity conferred was indistinguishable from that conferred by wild-type P22 repressor: when 10^8 λimm^{P22} phages were spotted on a lawn of cells producing 434R [$\alpha 3$ (P22R)],

A . T . A A G C T T . A . T P22 Operator
A C A A T T G T 434 Operator

Fig. 2 Consensus sequences for P22 and 434 operators. Shown are consensus sequences along one DNA strand for P22 and 434 operators^{13,23}, aligned at their centres of symmetry which are indicated by ●. An × in either sequence indicates a non-conserved base at that position of the operator.

Fig. 3 Binding of 434R [$\alpha 3$ (P22R)] to P22 O_R *in vitro*. Autoradiogram resulting from a typical DNase I protection experiment in which purified P22 repressor or 434R [$\alpha 3$ (P22R)] was bound to DNA containing wild-type P22 O_R . End-labelled DNA fragments in the lane marked A + G were cleaved at purines to generate size markers. The boundaries of each 18-bp binding site (O_{R1} , O_{R2} , and O_{R3}) are indicated on the left of the figure. Lanes a–g represent the electrophoresis of binding reactions that contained successively higher concentrations of P22 repressor. Lanes h–n represent the electrophoresis of binding reactions that contained successively higher concentrations of 434R [$\alpha 3$ (P22R)]. In all the reactions, the concentration of O_R -containing DNA fragments was $\sim 10^{-10}$ M. The concentrations of active protein monomers in each binding reaction were as follows: a, 0; b, 7.6×10^{-10} M; c, 1.3×10^{-9} M; d, 2.2×10^{-9} M; e, 3.7×10^{-9} M; f, 6.2×10^{-9} M; g, 1.1×10^{-8} M P22 repressor; and h, 0; i, 5.2×10^{-9} M; j, 8.8×10^{-9} M; k, 1.5×10^{-8} M; l, 2.5×10^{-8} M; m, 7.0×10^{-8} M; n, 5.6×10^{-7} M 434R [$\alpha 3$ (P22R)]. At saturating concentrations of each protein, both P22 repressor and 434R [$\alpha 3$ (P22R)] protect from DNase I cleavage regions of equivalent size, even though the precise boundary of the protected region below O_{R1} is not readily apparent because DNase I cleaves only weakly in this region. Examination of over-exposed autoradiograms reveals that the region protected by both proteins extends to the G residue 5 bp outside O_{R1} on the labelled strand. We note that a single phosphodiester bond within O_{R1} is not protected from DNase I cleavage by binding of P22 repressor although it is protected by 434R [$\alpha 3$ (P22R)]. (This phenomenon has been observed previously²⁴.) Using a DNA fragment labelled on the other strand, we observed that all of the phosphodiester bonds within O_{R1} were protected by each protein. The protein used in the experiment shown in the figure was *pcA* P22 repressor (see Fig. 1 legend). We have observed no significant differences between the binding of wild-type P22 repressor and *pcA* P22 repressor to O_R DNA. A detailed analysis of the binding of wild-type P22 repressor to O_R has been reported by Poteete and Ptashne²⁴. In the experiment shown here, we observed half-maximal occupancy of O_{R1} at a concentration of 1.0×10^{-9} M P22 repressor and at 8.8×10^{-9} M 434R [$\alpha 3$ (P22R)]. In nitrocellulose filter-binding experiments³⁵, the concentrations of 434R [$\alpha 3$ (P22R)] and P22 repressor monomers required to retain on the filter one-half of the DNA fragments in binding reactions were 1.6×10^{-10} M and 3.5×10^{-9} M, respectively (data not shown). In these experiments, the concentration of DNA fragments was 5×10^{-12} M, and the binding reaction conditions were slightly different (see methods). The concentrations of P22 *pcA* repressor required for half-maximal operator occupancy that we have determined in these experiments are virtually identical to those determined earlier for wild-type P22 repressor^{22,24}. From DNase I protection experiments similar to that shown here, we deduced the following ratios of protein concentrations required for half-maximal occupancy of O_{R1} , O_{R2} and O_{R3} on a DNA fragment-bearing wild-type O_R : for P22 *pcA* repressor, 1:1.5:6; and for 434R [$\alpha 3$ (P22R)], 1:1:6. The affinity order of P22 *pcA* repressor is identical to that determined earlier for wild-type P22 repressor²⁴. In the absence of cooperative interactions, threefold higher concentrations of P22 *pcA* repressor or of 434R [$\alpha 3$ (P22R)] were required to occupy O_{R3} half-maximally than were required to occupy O_{R1} half-maximally in DNase I protection experiments in which each site was present on a separate DNA fragment (data not shown). For each of three proteins, we list below the highest concentration tested at which we did not detect specific binding to non-cognate operator DNA and the ratio of this value over the concentration at which specific binding to cognate operator DNA was detectable: 434 repressor, 4×10^{-6} M, 100; P22 *pcA* repressor, 2×10^{-7} M, 300; 434R [$\alpha 3$ (P22R)], 1×10^{-6} M, 100.

Methods. 434R [$\alpha 3$ (P22R)] was purified from cells containing pRW219 following the same protocol by which 434 repressor has been purified³⁶. We measured the stability of 434R [$\alpha 3$ (P22R)] by digesting it with the thermo-stable protease thermolysin at various temperatures¹⁴. The amino-terminal domain of wild-type 434 repressor was stable to digestion at temperatures as high as 60°C whereas the amino-terminal domain of 434R [$\alpha 3$ (P22R)] was stable to digestion only at temperatures as high as 37°C (data not shown). We have not investigated further this apparent instability of 434R [$\alpha 3$ (P22R)] *in vitro*. Three different end-labelled DNA fragments were used in the binding experiments described in the figure: a *HindIII*/*CfoI* fragment from pTP37 (ref. 24) which contains wild-type P22 O_R ; an *EcoRI*/*HindIII* fragment from pRW253 which contains O_{R1} ; and an *EcoRI*/*HindIII* fragment from pRW254 which contains O_{R3} . (The asterisk indicates the labelled end of each fragment.) pRW253 and pRW254 were generated by partially cleaving a fragment of pTP37 with *HinfI* (which cleaves within O_{R2}), and then separately cloning the appropriate O_{R1} - and O_{R3} -containing DNA fragments into pEMBL8+. The reaction conditions for DNase I protection experiments were: 10 mM HEPES (pH 7.0), 200 mM KCl, 1 mM $MgCl_2$, 0.5 mM $CaCl_2$, 100 $\mu g ml^{-1}$ sonicated chick blood DNA at 23°C. The reaction conditions for the nitrocellulose filter binding experiment described in the legend were identical except that the divalent cations and chick blood DNA were omitted.

to lysis of the cells was apparent. Also, production of 434R [$\alpha 3$ (P22R)] had no detectable effect on the number or size of plaques formed by λimm^{434} phages (see Table 1). Thus, the five amino-acid substitutions introduced into 434 repressor to create 434R [$\alpha 3$ (P22R)] have switched the biological specificity of the protein from 434 operator binding to P22 operator binding.

Another observation from these physiological tests supports our conclusion that 434R [$\alpha 3$ (P22R)] has a negligible affinity for 434 operators. Wild-type λimm^{434} phages (encoding a functional repressor) form turbid plaques when spotted on lawns of either wild-type cells or cells producing P22 repressor, whereas mutant λimm^{434} phages (encoding a defective repressor) form clear plaques on the same lawns. We found that wild-type λimm^{434} phages, when spotted on a lawn of cells producing 434R [$\alpha 3$ (P22R)], formed clear rather than turbid plaques (see Table 1). We imagine that this interference with the function of the repressor encoded by the infecting λimm^{434} phages is a result of the fact that heterodimers of 434 repressor and 434R [$\alpha 3$ (P22R)] do not bind to 434 operators. We know that 434 repressor, which binds as a dimer, is a two-domain protein in which the amino-terminal domain mediates DNA binding

and the carboxy-terminal domain mediates dimerization^{13,21}. As 434R [$\alpha 3$ (P22R)] and wild-type 434 repressor have the same carboxy-terminal domains, they presumably form heterodimers efficiently. In the presence of excess 434R [$\alpha 3$ (P22R)], virtually all of the 434 repressor in cells infected with wild-type λimm^{434} phages would be sequestered in the form of mixed dimers; these mixed dimers evidently do not bind with significant affinity to 434 operator DNA.

434R [$\alpha 3$ (P22R)] activity *in vitro*

Purified 434R [$\alpha 3$ (P22R)] bound specifically to DNA containing the right operator (O_R) of phage P22 in DNase I protection experiments (Fig. 3). P22 repressor and 434R [$\alpha 3$ (P22R)] identically protected the same regions of O_R -containing DNA from DNase I cleavage with one exception: P22 repressor did not protect a single phosphodiester bond within O_{R1} that is protected by binding of 434R [$\alpha 3$ (P22R)] (see Fig. 3). As expected, based on the operator specificity exhibited by 434R [$\alpha 3$ (P22R)] *in vivo* (see Table 1), we failed to observe specific binding of 434R [$\alpha 3$ (P22R)] (or P22 repressor) to 434 operator DNA even at high repressor concentrations (see Fig. 3 legend). Similarly, we failed to observe specific binding of 434

Fig. 4 Activity *in vivo* of recombinants between 434 repressor and 434R [$\alpha 3$ (P22R)]. The diagram on the left indicates schematically the identity of the amino acids in the recognition helix of each protein. P22 repressor-derived amino acids from 434R [$\alpha 3$ (P22R)] are indicated by open boxes and 434 repressor-derived amino acids by solid lines. For reference, we show a drawing of the recognition helix of 434 repressor in which each of the five amino acids that were substituted in creating 434R [$\alpha 3$ (P22R)] is circled and connected to a box containing the amino-acid substitution. Dashed vertical lines indicate the boundaries within the recognition helices of the three groups referred to in the text (A, B and C). As in Table 1, + indicates that a bacterial strain producing a particular protein was immune to infection (no apparent cell lysis) and - indicates the converse. In lines 7 and 8, +/- indicates that strains producing these proteins were partially immune by the following criteria: wild-type λ imm⁴³⁴ phages formed fewer, smaller plaques than they did on strains producing no repressor, and λ imm⁴³⁴ c (clear) phages formed fewer, smaller and more turbid plaques than they did on strains producing no repressor (data not shown). This turbidity presumably is caused by the growth of partially immune microcolonies in the centres of phage spots. Each of the proteins, except that of line 8, was tested under conditions where it constituted ~1% of total cellular protein as determined by examination of stained bands following gel electrophoresis of whole-cell lysates under denaturing conditions (unpublished data). The asterisk in line 8 indicates that production of high levels of this protein prevented the growth of cells. Therefore, the immunity conferred by this protein was tested under conditions where it constituted <1% of cellular protein.

Methods. Genes encoding the recombinants shown in lines 3 and 7 were generated by crossing the genes encoding 434 repressor and 434R [$\alpha 3$ (P22R)] at the *Mbo*I restriction enzyme cleavage sites common to the DNA fragments encoding their recognition helices (see Fig. 1c). Then the genes encoding the recombinants shown in lines 2, 4, 6 and 8 were generated by crossing the appropriate combinations of genes encoding the proteins shown in lines 1, 3, 5 and 7 at the *Taq*I restriction enzyme cleavage sites common to the DNA fragments encoding their recognition helices. In the DNA sequence shown in Fig. 1c, another site for the enzyme *Taq*I exists, but cleavage at this site is blocked by methylation *in vivo* at the overlapping site for the enzyme *Mbo*I. All the recombinant genes were ligated into a common backbone from the plasmid pRW220, and the resulting plasmids were then transformed into XA90(F' *lac*^{O1}) cells for immunity tests (see Table 1). pRW220 is a derivative of pRW88 (ref. 13) in which the 248-bp *Eco*RI/*Hind*III fragment was replaced by the ~75-bp *Eco*RI/*Hind*III fragment from the plasmid π VX (ref. 37). The DNA sequence of the relevant portion of each of the genes was confirmed by the chain termination method³⁸. The level of each protein *in vivo* was estimated as described in Table 1.

repressor to P22 operator DNA *in vitro*. Comparable concentrations of either P22 repressor or 434R [$\alpha 3$ (P22R)] monomers were required to occupy *O_R* DNA half-maximally in several different DNA-binding experiments (see Fig. 3 legend). We cannot assign precise values for the affinity of the dimer of either protein as we do not know the value of the equilibrium constant for the dimerization reaction of either protein. Dimerization of P22 repressor and of 434 repressor (and therefore presumably also of 434R [$\alpha 3$ (P22R)]) is mediated in each case mainly by association of carboxy-terminal domains^{21,22}; these domains are different in the two proteins.

The experiment shown in Fig. 3 also demonstrates that a more subtle characteristic of the binding of 434R [$\alpha 3$ (P22R)] to P22 operators was similar to that of P22 repressor. In *O_R*, there are three similar but not identical 18-base-pair (bp) sites (named *O_R1*, *O_R2* and *O_R3*) (ref. 23), and P22 repressor binds to these sites on a DNA molecule bearing wild-type *O_R* with the affinity order *O_R1* ≈ *O_R2* > *O_R3* (ref. 24). As shown in Fig. 3, 434R [$\alpha 3$ (P22R)] bound with the same affinity order as did P22 repressor. Both P22 repressor and 434 repressor (and therefore presumably also 434R [$\alpha 3$ (P22R)]) bind cooperatively to adjacent operator sites on a single DNA molecule, and this cooperativity is mediated by the carboxy-terminal domain of each protein^{13,21,22,24}. We also measured the relative affinities of each protein for *O_R1* and *O_R3* in the absence of cooperative interactions. In DNase I protection experiments with *O_R1* and *O_R3* on two different DNA molecules, P22 repressor and 434R [$\alpha 3$ (P22R)] each bound with higher affinity to *O_R1* than to *O_R3* (see Fig. 3 legend).

Subdividing helix 3

We wished to determine whether all of the five amino-acid substitutions introduced in creating 434R [$\alpha 3$ (P22R)] were required for the ability of the protein to bind to P22 operators. Therefore, we took advantage of restriction enzyme cleavage sites present inside the regions encoding the recognition helices of 434 repressor and 434R [$\alpha 3$ (P22R)] (see Fig. 1c). We divided the five amino-acid substitutions into three groups (referred to below as groups A, B and C) and studied the activity *in vivo* of the various recombinants shown in Fig. 4. Group A consists of the three amino-acid substitutions at positions -1, 1 and 2 in the recognition helix; group B consists of the single amino-acid substitution at position 5; and group C consists of the single amino-acid substitution at position 9. All of the proteins referred to in Fig. 4 were stable *in vivo* by the following criterion: when the *lac* promoter driving expression of each protein was fully derepressed, each protein constituted ~1% of cellular protein (data not shown).

We find that, first, the P22 repressor-derived amino acids of groups A and B were necessary and sufficient to determine P22-operator binding specificity. Because we have not attempted to separate the three amino acids in group A, we cannot specify the minimum number of amino-acid substitutions required for P22 operator-binding activity. Second, the 434 repressor-derived amino acids of group A were sufficient for detectable binding to 434 operators, but for full activity (comparable to that of wild-type 434 repressor), the 434 repressor-derived amino acids of both groups A and B were necessary. Third, for all of the

proteins in Fig. 4, the identity of the amino acid in group C (either Asn or Arg) had no detectable effect on the binding activity. Fourth, none of the proteins simultaneously recognized 434 operators and P22 operators.

We also observed that cells producing a 434 repressor protein bearing a single amino-acid substitution, the P22 repressor-derived serine of group B, exhibited the following peculiar property: fewer than 1 in 10^6 cells survived to form colonies when the *lac* promoter driving expression of this protein was fully derepressed. We speculate that the extreme toxicity of this mutant protein may be caused by a drastically enhanced affinity for nonspecific DNA. This phenotype has been observed by Nelson and Sauer²⁵ for a mutant λ repressor that bears a substitution of Ser for Gly at position 5 of its recognition helix.

Conclusions

The experiments reported here extend our earlier work in which we studied a hybrid 434 repressor bearing the recognition helix of 434 cro protein¹³. 434 repressor and cro protein have very similar DNA-binding activities: they each bind with high affinity to the same set of 434 operators. In addition, the amino-acid sequences of the two proteins are very similar in their DNA-binding domains¹⁰, and it was therefore possible to exchange directly the recognition helix of 434 cro protein for that of 434 repressor without otherwise altering either protein. The resulting hybrid repressor was stable and active, presumably because the amino-acid residues on the inside surfaces of the recognition helices of both proteins are nearly identical¹³.

In the experiments reported here, we studied a 434 repressor hybrid that bears the recognition helix of a more distantly related protein. 434 repressor and P22 repressor have different DNA-binding activities. Even at very high concentrations, neither protein binds detectably to non-cognate operators either *in vivo* or *in vitro*. The amino-acid sequences of the two proteins are sufficiently dissimilar that it seemed unlikely that simply substituting the P22 repressor helix for that of 434 repressor would have yielded a stable and functional protein. We therefore engineered the 434 repressor recognition helix, replacing amino acids on its outside surface with the appropriate amino acids of P22 repressor, and leaving amino acids on its inside surface

as 434 repressor amino acids to preserve the structure of the folded protein. The resulting protein bound specifically and with high affinity to P22 operators *in vivo* and *in vitro*. We conclude that the recognition helix of 434 repressor is the sole determinant in 434 repressor that distinguishes between two different specificities: binding to 434 operators or to P22 operators. Some part of P22 repressor other than its recognition helix may also make sequence-specific DNA contacts, but our results require that 434R [$\alpha 3$ (P22R)] make these contacts as well.

As the properties of P22 repressor and 434R [$\alpha 3$ (P22R)] are so similar, we further conclude that the recognition helices of 434 repressor and P22 repressor interact with their respective operators in very similar ways. This conclusion is contrary to other proposals for the recognition helices of λ repressor⁷, λ cro protein⁸ and *E. coli* CAP⁹. Model-building studies of possible structures of the protein-DNA complexes formed by these three proteins suggest that each of the three recognition helices interacts with its operator in a significantly different manner.

Our results are consistent with what has been learned from studying the structure of a 434 repressor-operator complex. Anderson *et al.*¹ have observed that α -helix 3 of 434 repressor (its recognition helix) lies in the major groove with its amino-terminal end in intimate contact with the surface of the operator. Our analysis of recombinants between 434 repressor and 434R [$\alpha 3$ (P22R)] suggests that the amino-terminal end of the recognition helix is more important in determining the binding specificity of the protein than is the carboxy-terminal end. Similar suggestions have been made for λ repressor² and *E. coli* CAP⁹ based on model building, and a recent report on the effects of amino-acid substitutions in the recognition helix of λ cro protein is also consistent with this idea¹⁸. Further experiments will be required to understand in detail the roles of individual amino acids on the outside surface of the recognition helix in operator binding.

We thank members of our laboratory, David Horowitz, Donald Morisato, Don Wiley and Steve Harrison for helpful discussions and comments on the manuscript. We also thank John Douhan III for a gift of purified P22 *pcA* repressor and Hillary Nelson and Robert Sauer for communication of their unpublished results. This work was supported by NIH grant GM 29109 to M.P. and Steve Harrison.

We have introduced a full-length complementary DNA of the T-cell antigen receptor β -chain into a mutant human T-cell line that lacked a complete β -chain messenger RNA, had a diminished level of α -chain transcript and did not express surface T3- or antigen receptor. Expression of the transfected β -chain led to a normal level of α -chain transcript and a structurally and functionally active T3 T-cell antigen receptor complex on the cell surface.

THE T-cell antigen receptor that functions to recognize foreign antigens is a disulphide-linked heterodimer of relative molecular mass (M_r) 80,000–90,000 (80–90 K), composed of an acidic α - and a basic β -chain^{1–3}. The human^{4–6} and murine^{7–9} cDNAs have recently been cloned, shown to undergo somatic rearrangements in T cells^{4–9} and are related^{4–9} to, but distinct^{10–12} from, immunoglobulin genes. The receptor heterodimer is associated on the cell surface with T3, a set of three non-covalently linked peptides of 20–28 K^{13–17}. In an attempt structurally and functionally to separate the antigen receptor and T3, we selected for mutants of the T-cell tumour line Jurkat, which lacked either T3 or the T-cell antigen receptor, using OKT3 or an antiidiotypic antibody (C305). However, all mutants, selected either way, failed to express both these molecules¹⁶ on the surface. We show here that three mutants that do not express a full length β -mRNA have diminished levels of α -chain specific RNA, and do not express surface T3. Transfection of one of the mutants with β -chain complementary DNA induced the expression of normal levels of α -chain mRNA and led to the expression of a functional T3/T-cell antigen receptor complex on the cell surface.

Intracellular T3 mRNA and proteins

The three subunits of T3 consist of a 26–28 K γ -chain and two chains of 20–30 K, one a glycosylated δ -chain and the other a non-glycosylated ϵ -chain^{18–20}. Using a cDNA probe to the T3 δ -chain (pGBC-9)²¹, we examined seven T3/T-cell antigen receptor-negative mutants of Jurkat derived from four separate mutagenizations¹⁶ for the presence of transcripts. A Northern blot²² obtained with RNA isolated from four of these mutants, the wild-type cell (Jurkat) and HPB-ALL (Fig. 1a), shows that all mutants examined make transcripts for the T3 δ -chain that are indistinguishable in size from the normal T3- δ transcript.

We also examined wild-type Jurkat and the mutants for intracellular T3 subunits by biosynthetic labelling with ³⁵S-methionine and ³⁵S-cysteine. Several hours of continuous labelling, immunoprecipitation and SDS polyacrylamide gel electrophoresis revealed that all mutants had a doublet at 22–23 K precipitated by anti-Leu 4 from the mutant that is indistinguishable from that detected in Jurkat (Fig. 1b). During shorter labelling periods (15 min), the γ -chain of T3 was also detectable with anti-Leu 4 antibody in all the mutants (data not shown). Endoglycosidase F digestion of the Leu 4 immunoprecipitates from all three cell lines resulted in the loss of only the upper band of the 22–23 K doublet and the appearance of two lower M_r bands of 15 and 17 K (data not shown). These results are consistent with the notion that the upper band of the doublet represents the glycosylated T3 δ -chain and the lower band the non-glycosylated T3 ϵ -chain, as described by others^{18,19,23}.

Either α - or β -chain mRNA in mutants

We examined the cells for transcription of the α - and β -chain genes. Figure 2a is a Northern blot of poly(A)-enriched RNA from Jurkat, along with seven T3 T-cell antigen receptor negative mutants, hybridized to a full-length β -chain probe. Jurkat expresses both a 1.3- and a 1.0-kilobase (kb) β -chain transcript^{24–26}; the 1.3-kb transcript of Jurkat represents a full-length completely rearranged gene containing $V_\beta 1D_\beta 1J_\beta 1C_\beta 1$ (V , variable; D , diversity; J , joining; C , constant regions), whereas the 1.0-kb transcript contains only a $J_\beta 2C_\beta 2$ gene segment²⁷. In three of the seven mutants examined, the 1.3-kb transcript was not detected, although the 1.0-kb transcript was always present (Fig. 2a, lanes 2, 4 and 7). In contrast, the other four mutants contained both 1.3- and the 1.0-kb transcripts that could not be distinguished by size from those detected in the wild-type Jurkat cells (Fig. 2a, compare lane 1 with lanes 3, 5, 6 and 8).

Figure 2b shows that Jurkat also contains a 1.5-kb transcript homologous to the α -chain cDNA probe (lane 1). Four mutants seem to contain greatly diminished levels of α -chain transcripts (lanes 2, 3, 4 and 7). Interestingly, three of these mutants lack the 1.3-kb β -chain transcript (lanes 2, 4 and 7). The remaining three mutants seemed to contain normal levels of both α - and β -chain mRNA.

Transfection with β -chain cDNA

We next investigated the effect of transferring cDNA encoding the β -chain into a mutant that does not express the full-length of 1.3-kb mRNA. We used the Friend spleen focus-forming virus (SFFV) long terminal repeat (LTR)^{28,29} as a transcriptional promoter for the 1.3-kb β -chain transcript from YT35 (ref. 4), which has been shown to be identical to that of Jurkat²⁷. The mammalian selectable marker from the plasmid pSV2-neo (ref. 30) provided positive selection of transfectants (Fig. 3). Protoplast fusion was performed as described previously³¹.

Expression in transfected mutants

Of 15 transfectants, 7 expressed abundant levels of both antigen receptor molecules and T3 antigenic epitopes³². An example of the fluorescence histograms obtained with one such transfected cell, PF-2.8, is compared with those obtained with the wild-type (Jurkat) and the recipient mutant J.RT3–T3.5 (Fig. 4). Note that although the densities of T3 and T-cell antigen receptor determinants in PF-2.8 are less than those observed in the wild-type Jurkat, PF-2.8 expressed abundant levels of both T3 and T-cell antigen receptor determinants compared with the T3/T-cell antigen receptor negative mutant, J.RT3–T3.5. In all seven of the positive transfectants, the relationship between the density of T3 and T-cell antigen receptor epitopes was constant, thus

Fig. 1 (Left) *a*, Northern blot analysis of four independently derived T3/T-cell antigen receptor negative mutants of Jurkat hybridized with the T3 δ -chain transcripts. 20 μ g total RNA from the indicated cells were electrophoresed in 1% formaldehyde gels, transferred to nitrocellulose and hybridized with a ^{32} P-labelled cDNA probe specific for the T3 δ -chain^{21,22}. Lane 1, J.EMS-T3.3; lane 2, Jurkat; lane 3, J.RT3-T3.5; lane 4, J.RT-T3.1; lane 5, S.S.; lane 6, HPB-ALL. *b*, SDS-PAGE of biosynthetically labelled T3 antigens in T3 T-cell antigen receptor negative mutants of Jurkat. Lysates of Jurkat (lanes 1 and 2), J.RT-T3.1 (lanes 3 and 4) and J.RT3-T3.5 (lanes 5 and 6) were prepared from cells labelled for 16 h with ^{35} S-methionine and ^{35} S-cysteine. Preformed immune complexes prepared with rabbit anti-mouse IgG and either normal mouse serum (lanes 1, 3, 5) or anti-Leu 4 ascitic fluid (lanes 2, 4, 6) were incubated with each lysate and washed according to previously described methods¹⁸. Isolated complexes were then dissolved in SDS sample buffer containing 2-mercaptoethanol and electrophoresed on a 11% polyacrylamide slab gel. Gels were dried and fluorography was performed using sodium salicylate. Shown in the left margin are the relative mobilities of M_r standards run in parallel lanes. The arrow indicates the 22–23 K doublet representing T3 proteins. Note that the higher M_r bands observed between 40 and 50K are probably contaminants as they are also seen in precipitates isolated with normal mouse immunoglobulin preformed complexes.

Fig. 2 Northern blot analysis of Jurkat and T3/T-cell antigen receptor negative mutants for β -chain (*a*) or α -chain (*b*) transcripts. 7 μ g poly(A)-enriched RNA were isolated from Jurkat or mutant cells, electrophoresed in a 1% formaldehyde gel, transferred to nitrocellulose paper and hybridized with ^{32} P-labelled nick-translated probe and washed as described elsewhere²². Probes specific for the β -chain (*a*) or α -chain (*b*) of the antigen receptor heterodimer were previously characterized^{4,6}. Lane 1, Jurkat; lane 2, S.S.; lane 3, J.RT-T3.1; lane 4, J.RT-C305.6; lane 5, J.EMS-T3.3; lane 6, J.EMS-C305.1; lane 7, J.RT3-T3.5; lane 8, J.RT3-C305.6. The relative masses (in kb) of the bands obtained are indicated in the margins.

reinforcing their interdependence for their surface expression. The remaining eight transfected clones had either minimal or undetectable densities of determinants recognized by OKT3 or C305 monoclonal antibody.

The clone PF-2.8 that expressed the reconstituted T3/T-cell antigen receptor complex was examined by Southern^{33,34} and Northern^{22,35} blot analyses using a nick-translated³⁵ probe to YT35 (ref. 4) to ensure that the new β -chain mRNA was encoded by the transfected DNA, which can be seen at a new 3.3-kb band in the transfected line PF-2.8 (Fig. 5a, lane 3) that is not present in the mutant J.RT3-T3.5 (lane 2) or the wild-type Jurkat cell (lane 1). Several other new bands can also be detected in

Fig. 3 Construction of plasmid pTBF-neo. The cDNA fragment specific for the β -chain was subcloned into vector pFP502EB511, downstream from the SFFV-LTR, to create plasmid YT35 (ref. 4). pTBF-neo was constructed as illustrated and then transfected into *Escherichia coli* strain DH1. The bacteria were cultured, converted into protoplasts and fused to J.RT3-T3.5 as described in Ochi *et al.*³¹. Cells were plated at a concentration of 10^5 cells per ml in 24-well culture plates and incubated for 48 h. Geneticin was added (2 mg ml^{-1}) to select for transfected clones. □, SFFV-LTR; ■, β -chain cDNA; ▨, neomycin; E, *EcoRI*; B, *BamHI*; P, *PstI*; K, *KpnI*.

PF-2.8, but they probably represent integration events that disrupt the LTR β -chain continuity. These data also show that there are no gross new genomic rearrangements of the β -chain in the mutant J.RT3-T3.5 compared with Jurkat.

Northern blot analysis (Fig. 5b) indicates that two new transcripts homologous with the β -chain are found in PF-2.8 (lane 3). Jurkat, the wild-type cell, contains a 1.3-kb (V-D-J-C rearrangement) and a 1.0-kb (J-C transcript) mRNA (lane 1)²⁷. Lane 2 confirms that the 1.3-kb transcript cannot be detected in J.RT3-T3.5 (ref. 8) and lane 3 shows that the transfected clone expresses new transcripts of 1.9 and 3.4 kb. The increase in size of the β -chain mRNAs presumably results from a

Fig. 4 Immunofluorescence analysis for a T3/T-cell antigen receptor negative mutant of Jurkat transfected with the β -chain cDNA. Initial studies indicated that the SFFV LTR could activate YT35 transcription in the rat cell line Rat-1 (data not shown). Using the technique of protoplast fusion, pTBF-neo was amplified in bacteria and the bacteria fused with the mutant J.RT3-T3.5. This mutant was shown to lack the complete 1.3-kb β -chain transcript and had a decreased level of α -chain mRNA. Transfected cells were selected for geneticin-resistant clones and subsequently expanded in culture. Resistant clones were assayed for surface antigen receptor and T3 with amonoclonal anti-clonotypic antibody, C305 (ref. 16) and monoclonal OKT3 antibody³², respectively, using indirect immunofluorescence as assessed by fluorescence flow cytometry. Jurkat (a); J.RT3-T3.5, a T3 T-cell antigen receptor negative mutant lacking the 1.3-kb β -chain transcript (b); and PF-2.8, a β -chain transfectant of J.RT3-T3.5 (c) were analysed by indirect immunofluorescence using fluoresceinated-Fab'2 goat anti-mouse immunoglobulin on a FACS IV cell sorter. Cells were first stained with a control non-reactive mouse myeloma (MOPC 195) or the indicated antibodies: OKT3 (anti-T3), C305 (anti-receptor) or w6/32 (anti-HLA).

combination of different RNA initiation and termination sites of the newly introduced DNA and makes it unlikely that they represent reactivation of the original β -chain gene.

Initial Northern blot analysis (Fig. 2) indicated that the level of α -chain transcripts was diminished in J.RT3-T3.5. Northern blot analysis of RNA of the transfected line revealed that the level of α -chain transcripts in PF-2.8 (Fig. 5c, lane 3) is comparable in magnitude with that observed in Jurkat (lane 1) and clearly increased from the level observed in the mutant J.RT3-T3.5 (lane 2). These results suggest that transfection of the full-length β -chain into J.RT3-T3.5 induces increased levels of α -chain transcripts.

Reconstituted T3/antigen receptor is active

Previous studies have demonstrated that two stimuli are required for the activation of Jurkat, as measured by interleukin-2 (IL-2) production^{36,37}. One stimulus increases cytoplasmic free calcium $[Ca^{2+}]_i$ and can be provided by the lectin phytohaemagglutinin (PHA), calcium ionophores (A23187 or ionomycin) or monoclonal antibodies reactive with the T3/T-cell antigen receptor complex^{37,38}. The second stimulus can be provided by phorbol

Fig. 5 Molecular analysis of transfectant PF-2.8. **a**, Southern blot analysis. 10 μ g DNA isolated from Jurkat (lane 1), J.RT3-T3.5 (lane 2), PF-2.8 (lane 3) and pTBF-neo (lane 4) were digested with *Eco*RI and *Bam*HI, electrophoresed in an 0.8% agarose gel, transferred to nitrocellulose and hybridized as described³³. The probe was the ³²P-labelled nick-translated ³⁴*Eco*RI/*Bam*HI fragment of pTBF-neo that contains β -chain cDNA. **b**, Northern blot analysis for β -chain transcripts in PF-2.8. 7 μ g poly(A)-enriched RNA was isolated from Jurkat (lane 1), J.RT3-T3.5 (lane 2) and PF-2.8 (lane 3) and was electrophoresed in a 1% formaldehyde gel, transferred to nitrocellulose³⁵ and probed with ³²P-labelled nick-translated β -chain cDNA. **c**, Northern blot analysis for α -chain transcripts in PF-2.8. 7 μ g poly(A)-enriched RNA isolated from Jurkat (lane 1), J.RT3-T3.5 (lane 2) and PF-2.8 (lane 3) were electrophoresed in a 1% formaldehyde gel, transferred to nitrocellulose³⁵, and probed with ³²P-labelled nick translated α -chain cDNA⁶. Numbers in the margins indicate M_r (kb).

Fig. 6 Changes in $[Ca^{2+}]_i$ in response to anti-receptor (C305) in Jurkat (a); the T3/antigen receptor negative mutant, J.RT3-T3.5 (b); and the β -chain transfectant, PF-2.8 (c). Cells were loaded with the acetoxymethyl ester of quin-2, 20 μ M. Calcium-sensitive quin-2 fluorescence of 10^7 cells per ml was continuously monitored in a Perkins-Elmer 650-40 spectrofluorimeter as previously described³⁷. Interruption in the tracings represent mixture of the cell suspension or addition of C305 (1:300 final dilution of hybridoma culture suspension or addition of C305 (1:300 final dilution of hybridoma culture supernatant) or ionomycin, 1 μ M. $[Ca^{2+}]_i$ was calculated according to the method of Tsien *et al.*³⁹.

myristate acetate (PMA). To investigate whether the reconstituted T-cell antigen receptor on the transfected line PF-2.8 was biologically functional, we measured changes in $[Ca^{2+}]_i$ in response to C305 antibody using quin-2, a calcium-sensitive dye. Whereas C305 induced a prompt and sustained rise in $[Ca^{2+}]_i$ in Jurkat (Fig. 6a), it failed to increase $[Ca^{2+}]_i$ in the T3/T-cell antigen-receptor complex negative mutant, J.RT3-T3.5 (Fig. 6b). However, $[Ca^{2+}]_i$ was increased in J.RT3-T3.5 by the calcium ionophore ionomycin (Fig. 6b). When C305 was added to the transfected line PF-2.8, the increase in $[Ca^{2+}]_i$ was restored (Fig. 6c), suggesting that the reconstituted T3/T-cell antigen receptor complex on PF-2.8 was functional. We have demonstrated previously that mutants of Jurkat that fail to express the T3/T-cell antigen receptor complex fail to produce IL-2 in response to PHA plus PMA^{16,37}. Reconstitution of the T3/T-cell antigen receptor complex restored the PHA responsiveness of PF-2.8 as detected by IL-2 production (data not shown). Thus, the transfection of the β -chain gene resulted in not only reconstitution of the expression of the T3/T-cell antigen receptor structural proteins, but also in a functional receptor.

Discussion

The absence of 1.3-kb β -chain transcripts associated with diminished levels of α -chain transcripts could be explained by a defect in a common regulatory element. In this case, however, the presence of a β -chain transcript regulated by the extraneous promoter should not be able to compensate for a defective regulatory protein at the normal α -chain locus. Alternatively, expression of the β -chain may effect the transcriptional level of the α -chain. Results presented here (Fig. 5) provide support for the latter alternative as transfection of the β -chain cDNA into J.RT3-T3.5 results in an increased appearance of α -chain transcripts. Additionally, because the 1.0-kb β -chain transcripts are made in mutants that fail to contain 1.3-kb β -chain transcripts, it is likely that the genes encoding these transcripts have separate regulatory control.

The reconstitution of the T3/T-cell receptor complex using β -chain cDNA suggests that expression of both α - and β -chain proteins is a requirement for the cell-surface expression of T3 proteins. This is in general agreement with the observation that

the cell-surface appearance of T3 on immature T-leukaemic lines and the thymus is coordinated with the appearance of the T-cell receptor heterodimer².

This intimate association between T3 and the T-cell heterodimer may serve as both a structural and functional molecular complex in T-cell activation. We have demonstrated previously that the T3/T-cell antigen receptor complex initiates activation by mechanisms that lead to increases in cytoplasmic free calcium³⁷⁻³⁹. Triggering the T3/T-cell antigen receptor complex results in polyphosphoinositide metabolism and subsequent release of inositol trisphosphate, which in turn induces a rise in cytoplasmic free $[Ca^{2+}]_i$ by the release of intracellular $[Ca^{2+}]_i$ stores⁴⁰. Thus, the association of T3 and the T-cell antigen receptor may represent both a structural interaction necessary for cell-surface expression and a functional interaction necessary for the mechanisms responsible for increases in cytoplasmic free $[Ca^{2+}]_i$. It is clear that the disulphide-linked heterodimer is involved in an antigen binding function. The role of T3 has not been defined, but we suggest that its function is to initiate activation by causing turnover of polyphosphoinositides and mobilization of intracellular calcium.

Finally, the reconstitution of a biologically active receptor by DNA transfer provide direct evidence that β -chain mRNA encodes a protein that constitutes part of the T-cell receptor, and these data provide a basis for further examination of T3/T-cell antigen receptor as a recognition and signal transduction molecular complex.

Skyhook gravitational-wave detector

Vladimir B. Braginsky

Physics Faculty, Moscow State University, Moscow, USSR

Kip S. Thorne

Theoretical Astrophysics, California Institute of Technology,
Pasadena, California 91125, USA

Gravitational waves in the 10–100-mHz band are inaccessible to Earth-based detectors because of seismic noise. Hitherto, the most sensitive detectors in this frequency band have been the Doppler tracking of interplanetary spacecraft¹ and excitations of seismic motions in the Earth's surface^{2,3}. Here we propose a new and more sensitive type of Earth-orbiting gravitational-wave detector, called a 'skyhook', which would operate in the 10–100 mHz band. The skyhook would consist of two masses, one on each end of a long thin cable with a spring at its centre. As it orbits the Earth, the cable would be stretched radially by the Earth's tidal gravitational field. Gravitational waves would pull the masses apart and push them together in an oscillatory fashion; their motion would be transmitted to the spring by the cable; and a sensor would monitor the spring's resulting motion. (An analogous skyhook, for non-gravitational-wave purposes, was proposed by Colombo⁴ *et al.* 10 years ago and is planned for flight on the space shuttle⁵).

The Doppler tracking¹ of interplanetary spacecraft and seismic motions^{2,3} have r.m.s. noise of $h \sim 3 \times 10^{-13}$ in each case. Hellings has pointed out to us that the evaluation of the h sensitivity of seismic motions in his ref. 1 is incorrect by a factor of $\sim 6\pi$ (Earth radius)/(sonic wavelength). We express the noise level of a gravitational-wave detector in terms of $h = f^{1/2}h(f)$, where $h(f)$ is the square root of the spectral density of the transverse-traceless part of the metric perturbation at frequency f . At the end of this century expensive laser interferometric detectors^{6,7} might fly in space with noise levels $h \sim 10^{-21}$. The skyhook could be a relatively inexpensive and unsophisticated broad-band, Earth-orbiting detector, with sensitivity $h \sim 3 \times 10^{-17}$, intermediate between the present detectors and the envisioned interferometric systems.

By integrating for several weeks, the skyhook could detect the gravitational waves from binary stars with periods of order 1 min and wave amplitudes of the order of 10^{-19} , including, for example, the waves that are predicted to come from Geminga according to the Bisnovatyi-Kogan model⁸ ($0.6M_{\odot}$ white dwarf in a 1-min period orbit around a $5M_{\odot}$ black hole at a distance 100 pc from Earth) or the Nulsen-Fabian⁹ model (two neutron stars in a several-minute-period orbit at 10-pc distance).

Illustrative parameters for the skyhook are: the masses on the cable ends might be $m_0 = 20$ kg. The cable might have a length $L = 25$ km, diameter $d = 0.6$ mm, and cross-sectional area $S = 0.0028$ cm². It might be made of a composite material with thermal expansion coefficient $\alpha = 10^{-7}$ K⁻¹, density $\rho = 3$ g cm⁻³, and Young's modulus $Y = 1 \times 10^{12}$ dyn cm⁻². In this case, the cable's mass would be $m_c = \rho SL = 21$ kg, its speed of longitudinal sound waves would be $v_s = (Y/\rho)^{1/2} = 5.8 \times 10^5$ cm s⁻¹, and the rigidity of its top half (or bottom half) would be $K_c = 2YS/L = 2.3 \times 10^3$ dyn cm⁻¹. The spring at the cable's centre might have a rigidity for each half (top or bottom) of $K_s = 2.3 \times 10^3$ dyn cm⁻¹. Then the effective mass of each half of the system would be $m = m_0 + m_c/4 = 25$ kg, the net spring constant of each half of the system would be $K = K_c K_s / (K_c + K_s) = 1,200$ dyn cm⁻¹, the angular eigen frequency of the system would be $\omega_0 = (K/m)^{1/2} = 0.22$ s⁻¹, and the eigen frequency would be $f_0 = \omega_0/2\pi = 35$ mHz. Internal dissipation in the cable and spring might give the eigen oscillations a quality factor $Q = 10^5$. The tidal force on each half of the system relative to its centre, augmented by the centrifugal force due to the rotation of the skyhook as it orbits the Earth, would be $F_t = m(f/2)\Omega^2 = 9.4 \times 10^4$ dyn where $\Omega = 1.0 \times 10^{-3}$ s⁻¹ is the

skyhook's orbital angular velocity around the Earth. This tidal force would stretch the spring by an amount $x = 2F_t/K_s = 82$ cm.

A gravitational wave with amplitude $h \sim 10^{-17}$ and frequency $f = 2\pi\omega$ in the 10–100-mHz band would produce oscillatory changes of spring length with magnitude $\Delta x \sim m\omega^2 h L / 2K_s \sim 10^{-11}$ cm; this is large enough for a simple sensor to read it out in a time $< 1/\omega \sim 5$ s. Thus, the detector would have a broad-band response.

The length of the cable is limited by the demand that it transmit the gravitational-wave force directly to the spring without excitation of cable sound waves. This requires that the cable length L be equal to about half the sonic wavelength at the highest gravity-wave frequency of interest, $f_{\max}$: that is, $f_{\max} \approx v_s/2L \approx 100$ mHz. The detector would still have some sensitivity at frequencies higher than this, but its response would be debilitated and complicated by the cable's sound waves.

Six noise sources look as though they might produce serious problems for the skyhook: Nyquist noise produced by the fluctuating part of the skyhook's internal dissipation; fluctuations in cable length produced by fluctuations in solar and Earth heating; fluctuation forces due to the gravity gradients of the high harmonics of the Earth; fluctuating electrical and magnetic forces; micrometeoroid impacts; and atmospheric drag.

The spectral density of the Nyquist force acting on each half of the spring is $S_F = 4mkT\omega_0/Q$, where k is Boltzmann's constant and $T \approx 300$ K is the skyhook's temperature. As the spectral density of the gravity-wave force on each half of the spring is $S_F = [m(L/2)\omega^2 h(f)/2]^2$, with $f = \omega/2\pi$, the Nyquist noise expressed in gravitational-wave units is

$$h_{\text{Nyq}} = f^{1/2}h(f) = \left(\frac{32}{\pi} \frac{kT\omega_0}{mL^2\omega^3 Q} \right)^{1/2} = 3 \times 10^{-17} \left(\frac{f}{30 \text{ mHz}} \right)^{-3/2}$$

The cable is continually being heated by radiation from the Sun and Earth (energy flux $F = 1.7 \times 10^6$ erg cm⁻² s⁻¹) and cooled by emission of radiation into space. If the cable is painted white so that its albedo is $A = 0.97$, and if its specific heat is $C = 6 \times 10^6$ erg g⁻¹ K⁻¹, then its thermal response time (e -folding time for temperature to return to equilibrium after a sudden change of irradiating flux) is $t_T = \pi C \rho T d / 32 F (1 - A) = 600$ s. A fractional oscillation $\Delta F/F$ in irradiating flux at angular frequency ω will produce a fractional oscillation $\Delta T/T = (1/4\omega t_T) \Delta F/F = (1/500)(30 \text{ mHz}/f) \Delta F/F$ in the cable's temperature T . This, in turn, will produce a fractional oscillation $\Delta L/L = \alpha \Delta T = 6 \times 10^{-8} (30 \text{ mHz}/f) \Delta F/F$ in the cable's length, which, in turn, will produce an oscillating tidal force on the top or bottom half of the cable $\Delta F_t = 3m\Omega^2 \Delta L/2$. By equating this with the corresponding gravitational-wave force, we see that the noise produced by fractional fluctuations $\Delta F/F$ in irradiating flux at frequency f is $h_{\text{heat}} = 6(\Omega/\omega)^2 (\alpha T/4\omega t_T) \Delta F/F = 1 \times 10^{-11} (30 \text{ mHz}/f)^3 \Delta F/F$. Thus, if the skyhook is to have a sensitivity of $h \sim 3 \times 10^{-17}$ at $f \sim 30$ mHz, the fractional fluctuations in irradiating flux at 30 mHz and in a bandwidth of order 30 mHz must either be below 3×10^{-6} or be monitored by an instrument onboard the skyhook to this sensitivity.

There are no data with the required accuracy on fluctuations in the solar luminosity in the 10–100-mHz band, but at 1 mHz the ACRIM (Active Cavity Radiometer Irradiance Monitor) detector on the SMM (Solar Maximum Mission) spacecraft reveals¹⁰ $\Delta F/F = 30 \times 10^{-6}$, and as one moves upward in frequency by a factor 30, $\Delta F/F$ may well drop off¹¹ by a factor of 10, to 3×10^{-6} . However, for safety one might wish to monitor the Sun's irradiating flux.

Fluctuations in the Earth's surface temperature and albedo with spatial wavenumber $k = 1/40$ km will produce, as the skyhook orbits the Earth with speed 8 km s⁻¹, fluctuations $\Delta F/F$ at frequency 30 mHz. If the skyhook is at an altitude z above the Earth's surface, $\Delta F/F$ will be reduced below the fractional fluctuations of Earth's temperature and albedo by a factor $\sim \exp(-kz)$, which is $< 10^{-6}$ for altitudes > 550 km. Thus, for orbital altitudes above 550 km, fluctuations in the Earth's radiation are probably not a problem.

The radiative heating of the cable will also vary due to fluctuations in the direction of the cable. However, it seems unlikely that anything will produce fluctuations on the relevant timescale large enough to be a problem.

Of course, whenever the skyhook moves into and out of the Earth's shadow its temperature will change by $\Delta T/T \sim 1/3$; and afterward the cable will require a time of order $t_r \ln 10^8 \sim 3.1$ h to settle back down to a length sufficiently steady for gravity-wave observations. As the orbital period is only ~ 1.7 h, gravity-wave observations will be possible only from a high-inclination orbit where there are long stretches of non-shadow time.

Heating and cooling due to passage through the shadow will probably enhance sudden strain releases (creep) in the cable, and the presence of such creep may necessitate doing experiments with two or more skyhooks simultaneously and cross-correlating their data. Fortunately, each shadow passage will probably cause some annealing of the cable; and, as a result, creep will probably become less serious as the cable ages.

If the skyhook is flown in too low an orbit, noise from the Earth's gravity gradients will be a problem. Fluctuations, $\Delta\sigma$, in the Earth's surface density of mass with wavenumber $k = \omega/v_{\text{orb}} = (1/40 \text{ km})(f/30 \text{ mHz})$ will produce a tidal force on the top (or bottom) half of the skyhook $\Delta F_t = \pi m G \Delta\sigma (kL) \exp(-kz)$. Equating this to the gravity-wave force $m\omega^2 hL/4$, we obtain for the gravity-gradient noise in gravitational-wave units, $h_{\text{gg}} = (4\pi G \Delta\sigma / \omega v_{\text{orb}}) \exp(-kz)$. For $\Delta\sigma = 3 \times 10^5 \text{ g cm}^{-2}$ and $f = 30 \text{ mHz}$, a skyhook altitude of $z > 1,000 \text{ km}$ will keep $h_{\text{gg}} < 10^{-17}$. The skyhook could function as a good gravity-wave detector at lower altitudes only after the Earth's gravity gradients on scales $k \sim 1/40 \text{ km}$ have been adequately mapped.

Of course, the skyhook itself could be used to map the Earth's gravity gradients, but only one of their six components, the radial-radial component. The skyhook's sensitivity to this component would be $\Delta\Phi_{rr} = \omega^2 h/2 \sim 5 \times 10^{-19} \text{ s}^{-2}$ in a bandwidth $\Delta f \sim f \sim 30 \text{ mHz}$, which corresponds to $\sim 3 \times 10^{-18} \text{ s}^{-2} \text{ Hz}^{-1/2}$. This is far more accurate than the $10^{-13} \text{ s}^{-2} \text{ Hz}^{-1/2}$ sensitivity of the best gravity gradiometer being developed for flight in space¹², but that gradiometer would measure all six components of the Earth's tidal field, not just the radial-radial component.

The earth's magnetosphere exhibits $f = 10$ – 100 -mHz standing-wave Alfvénic excitations, called Pc2,3,4 and Pil,2 micropulsations¹³, which will interact with the skyhook to produce debilitating noise. On magnetic field lines which cross the geomagnetic equator at ≥ 3 Earth radii ($L \geq 3$ field lines) these micropulsations are present about 50% of the time and have electrical and magnetic field amplitudes $\Delta B \sim (0.1\text{--}100) \text{ nT} = (10^{-6}\text{--}10^{-3}) \text{ G}$; $\Delta E = [(\text{Alfvén velocity})/c] \Delta B \sim (0.1\text{--}100) \text{ mV m}^{-1}$ (refs 13, 14). On field lines with $L \leq 3$, the $f = 10$ – 100 mHz micropulsations may be less frequent and weaker,^{14,18} and presumably the predominant quiet-time fields have $\Delta B \leq 0.03 \text{ nT}$, $\Delta E \leq 0.03 \text{ mV m}^{-1}$.

If the skyhook's cable is a good conductor (resistivity $\mathcal{R} = 10^{-5} \text{ ohm cm}$; resistance $R_c = \mathcal{R}L/S = 9,000 \text{ ohm}$), then the electromotive force $\mathcal{E} = (v/c)BL = 6,000 \text{ V}$ caused by its $v = 8 \text{ km s}^{-1}$ motion through the Earth's $B = 0.3 \text{ G}$ field, will drive current to flow from the magnetosphere into one end region of the cable, along the cable, and out the other end region. Although the magnetospheric impedance for this flow is not well understood (refs 5, 15 and P. M. Banks, personal communication), it will surely be high enough to force the cable to develop a vertical gradient of charge density such that $\Delta q' = (\text{mean charge per unit length on upper half}) - (\text{mean charge per unit length on lower half}) \gg 10^{-3} \text{ ESU cm}^{-1}$. Such a charge difference, interacting with quiet-time electric-field fluctuations $\Delta E_z \sim 0.03 \text{ mV m}^{-1}$, would produce noise at the level $h_{\text{EM}} \gg 10^{-15}$. Thus, the cable must not be a good electrical conductor.

A nonconducting cable, like any satellite, will charge up to $V_0 \sim (a \text{ few } kT_e/e) \sim 1 \text{ V}$ in the plasma rest frame because the electron thermal velocity $(3kT_e/m_e)^{1/2}$ exceeds that of the ions and because of photoelectron emission from the cable's surface^{15,16}. The resulting charge per unit length on the cable will

have magnitude $q' \sim 4 \times 10^{-4} \text{ ESU cm}^{-1}$. This charge (essentially equal on the two halves of the cable) will interact with the vertical gradient (d/dz) of the vertical electric-field fluctuations ΔE_z to produce a stretching of the spring. The stretching force on the top (or bottom) half of the spring will be $F_{\text{EM}} \approx (d\Delta E_z/dz)(L^2/8)q'$. Equating this to a gravitational-wave force $\Delta F = m\omega^2 Lh/4$, we find for the electromagnetic noise in gravitational-wave units

$$h_{\text{EM}} \approx 3 \times 10^{-17} \left[\frac{L(d\Delta E_z/dz)}{0.004 \text{ mV m}^{-1}} \right] \left[\frac{30 \text{ mHz}}{f} \right]^2 \left[\frac{V_0}{1 \text{ V}} \right]$$

If the length scales for the vertical gradients of ΔE_z at quiet times are $\geq 10L = 250 \text{ km}$ and if $\Delta E_z \leq 0.03 \text{ mV m}^{-1}$, then h_{EM} will be $\leq 3 \times 10^{-17}$. However, during some micropulsations h_{EM} will be $\gg 3 \times 10^{-17}$. Thus, it will be necessary to carry on board the skyhook one or more electrical field probes to monitor ΔE_z ; and the skyhook orbit should be chosen to spend as much time as possible in the quiet region $L < 3$, that is $z < 6,400 \text{ km} \times (3 \cos^2 \theta_m - 1)$, where z is the orbital altitude and θ_m is the magnetic latitude.

To recapitulate, the orbital altitude must be $z \geq 1,000 \text{ km}$ to avoid gravity-gradient forces, and $z \leq 6,000 \text{ km}$ to maximize the time spent in quiet E -field regions. The inclination of the orbit to the Earth's Equator, i , must be large enough to permit a reasonable fraction of all orbits to be in full sunlight, $i \geq 90^\circ - \sec^{-1}(1 + z/R_\oplus) \approx [60^\circ \text{ if } z = 1,000 \text{ km}; 30^\circ \text{ if } z = 6,000 \text{ km}]$, but small enough (preferably $i \leq 65^\circ$) to minimize the time spent on noisy field lines with $L \geq 3$.

Approximately once per day the skyhook will encounter a swarm of micrometeoroids with individual masses $m \sim 10^{-13} \text{ g}$.¹⁷ The ~ 10 impacts per second during a ~ 10 min encounter will mimic gravity waves with $h \sim 3 \times 10^{-16}$ at $f \sim 30 \text{ mHz}$. Such impacts may be identifiable by the time development of the data; and they can be anticorrelated by cross correlating two skyhooks.

Air molecules striking the cable will transfer to it an average fraction $\mu = (\text{accommodation coefficient})$ of their longitudinal momentum. Correspondingly, vertical 'winds' in the residual atmosphere, with wind velocity fluctuations Δv_w and with scale height H for vertical momentum density, will produce a fluctuating longitudinal drag force which mimics gravitational waves with $h \sim [\mu(\Delta v_w/v_{\text{orb}})(L/8H)F_{\text{drag}}][m\omega^2 L/4]^{-1}$. Here F_{drag} is the total neutral-atmosphere-induced drag on the skyhook. This fluctuating drag may require the skyhook to fly at altitudes $z \geq 2,000 \text{ km}$, where $F_{\text{drag}} \leq 0.02 \text{ dyn}$, $H \geq 1,000 \text{ km}$, and

$$h \sim 3 \times 10^{-17} \left(\frac{\mu}{0.1} \right) \left(\frac{1,000 \text{ km}}{H} \right) \left(\frac{F_{\text{drag}}}{0.02 \text{ dyn}} \right) \left(\frac{\Delta v_w}{25 \text{ m s}^{-1}} \right) \times \left(\frac{30 \text{ mHz}}{f} \right)^2$$

and even then correlation drag fluctuations may require two-skyhook correlations for their removal. Charged-particle drag, which is much more difficult to analyze and is intimately connected to electromagnetic noise, might also be a problem.

Noise due to forces on the cable (drag, micrometeoroid, and electromagnetic) might be strongly reduced by using a more complicated skyhook design (suggestion by R.W.P. Drever): use a single cable (no central spring) with one spring at each end between cable and end mass; make the cable much stiffer than the two springs, $k_c \gg k_s$, so it acts as a rigid rod connecting them; and add the displacements of the springs.

The skyhook is, in summary, an attractive, simple instrument with gravity-wave sensitivity in an interesting range where sources might exist but are not guaranteed to exist.

We thank Peter Bender, Peter M. Banks, Bruno Bertotti, Mario Grossi, Donald Gurnett, Lou Lanzerotti, Forest S. Mozer, Masahisa Sugiura and Bruce Tsurutani for helpful discussions. This work was supported in part by the Ministry of Higher Education of the USSR and by NSF grant AST82-14126.

The geomagnetic mass spectrometer—mass and energy dispersions of ionospheric ion flows into the magnetosphere

M. Lockwood*§, T. E. Moore*, J. H. Waite Jr*, C. R. Chappell*, J. L. Horwitz† & R. A. Heelis‡

NASA's Dynamics Explorer (DE) mission was designed to study the coupling between the Earth's magnetosphere, ionosphere and neutral thermosphere¹. One area of major interest is the outflow of ionospheric plasma into the magnetosphere, the scale and significance of which is only now becoming apparent with the advent of mass-resolving, low-energy ion detectors. Here we compare observations of ion flows in the polar magnetosphere, made by the retarding ion mass spectrometer (RIMS)² on DE1, with those made simultaneously in the topside ionosphere by the ion drift meter (IDM)³ on the lower-altitude DE2 spacecraft. The results show the dayside auroral ionosphere to be a significant and highly persistent source of plasma for the magnetosphere. The upwelling ionospheric ions are spatially dispersed, according to both their energy and mass, by the combined actions of the geomagnetic field and the dawn-to-dusk convection electric field, in an effect analogous to the operation of an ion mass spectrometer.

The two DE satellites were launched into co-planar polar orbits on 3 August 1981; DE1 being in a highly elliptical orbit which carried it out to a geocentric distance, r , of 4.5 Earth radii (R_E), while DE2 remained at altitudes below about 1,000 km. During the first 18 months of the mission, the DE1 apogee precessed from the north to the south pole.

The RIMS instrument on DE1 comprises three detector heads, each an ion mass spectrometer with a potential analyser input, and each capable of observing ions of two mass-per-charge ratios simultaneously. Ion species of mass up to 32 AMU can be resolved and for each species an integral energy spectrum over the range 0–50 eV (relative to spacecraft potential) is obtained. The RIMS radial head sweeps through a full range of pitch angles twice during each satellite spin period of 6 s: Fig. 1 shows data from this radial head for a pass from north to the south polar regions on 3 April 1982. By this date, DE1 perigee was close to the geomagnetic equator (time C) and no data were obtained between times B and D, when the ambient

plasma density was too great for RIMS to operate. Figure 1 shows contours of O^+ and H^+ ion counts per accumulation period (12 ms) as a function of time and satellite spin angle. Count rates are approximately proportional to integral ion flux, one count per sample being roughly equivalent to 3.1×10^4 and $4.4 \times 10^4 \text{ cm}^{-2} \text{ s}^{-1} \text{ sr}^{-1}$ for H^+ and O^+ respectively; during most of this pass they were largest when the spin angle was close to zero, that is, when the radial head was looking along the orbit path or RAM direction. This indicates that the plasma was cold and isotropic and that ion flow velocities were much smaller than the spacecraft speed ($\sim 7 \text{ km s}^{-1}$ at $r = 2R_E$ and 10 km s^{-1} at $r = 1.1R_E$)⁴. Exceptions to this were the behaviour of H^+ ions in the northern polar cap (before 1157 UT, the time A), for which the peak count rate was shifted from the RAM direction towards the upward field-aligned direction (the upper of the two dashed lines), revealing upward field-aligned flow, as predicted for the light-ion polar wind^{5,6}; in addition the peak O^+ ion count rates near both magnetic poles (before about 1150 UT and after about 1240 UT) are shifted towards the downward field-aligned direction, indicating the ions are moving downward under the influence of gravity⁷. However, the largest flow features were seen at times A and E when DE1 passed through the morning sector auroral ovals in each hemisphere and strong upward flows were observed of both O^+ and H^+ ions.

These upflows have been termed 'upwelling ion events'⁴ as all ion species show the effects of equal ion heating below the satellite (to parallel and perpendicular temperatures of ~ 2 and 10 eV, respectively) and carry an upward heat flux. Ion species observed streaming upwards in these events include H^+ , He^+ , O^+ , N^+ and O_2^+ (ref. 7), and there is evidence that molecular ions N_2^+ , O_2^+ and NO^+ , seen by RIMS in the polar magnetosphere, may also originate from the events. The number fluxes of upwelling O^+ are very large, requiring of the order of 10^9 ions $\text{cm}^{-2} \text{ s}^{-1}$ out of the topside ionosphere, which is an order of magnitude larger than the cold polar wind flux summed over all ion species^{5,6}: the total O^+ outflow from both hemispheres has been estimated to average over 10^{25} s^{-1} which compares with an estimated polar wind outflow of $5 \times 10^{25} \text{ s}^{-1}$. A statistical survey of 2 years' RIMS data has shown that these events are a highly persistent phenomenon and are only found in a narrow region near the morning and noon polar cap boundaries⁴.

The interaction of the solar wind, and the interplanetary magnetic field (IMF) embedded within it, with the Earth's magnetosphere generates large-scale electric fields which give 'convection' of plasma at high latitudes. If the IMF has a southward component, this flow is anti-sunward over the polar cap.

Solar wind ions injected into the magnetosphere in the dayside auroral zone have been observed to be dispersed in mass, energy and pitch angle by this poleward motion⁸: lower velocity ions are found further poleward because their time of flight is greater and hence they are convected over greater distances. This effect should also be observed for the upwelling ionospheric ions described above, particularly at great altitudes where the dispersion should be larger.

Early in the DE mission, RIMS afforded an excellent opportunity to see dispersion of upflowing ionospheric ions, with DE1 apogee being over the northern polar cap. Figure 2 shows data from 22 October 1981 when DE1 and DE2 were in close magnetic conjunction over the northern dayside auroral region. The level of geomagnetic activity was moderately high ($K_p = 5$), for which the occurrence probability of upwelling ions is very close to unity⁴: the IMF was (and had previously been) predominantly southward, giving anti-sunward convection, as was observed by the IDM on DE2.

Figure 2a shows the retarding potentials required to reduce the count rates from the RIMS radial head to below two per sample, for upward field-aligned flows of H^+ , He^+ and O^+ ions near 22,000 km in altitude; these are estimates of the peak energy for each ion species. Figure 2c shows the field-aligned flow velocity and flux, as seen by the IDM during the DE2 pass at an altitude near 900 km. The arrows relate the observations to

§ Present address: Rutherford Appleton Laboratory, Chilton, Didcot OX11 0QX, UK

Fig. 1 Spin angle/time plots of count rate contours for O^+ and H^+ ions, observed during a pole-to-pole pass of DE1 on 3 April 1982 by the RIMS radial head. Zero spin angle corresponds to the satellite orbit direction and the upward field-aligned direction is shown by the dashed line in the Southern Hemisphere ($MLAT < 0$) and by the dashed-and-dotted line in the Northern Hemisphere. For each universal time (UT), the geocentric distance (r), magnetic local time (MLT) geomagnetic latitude (MLAT) and invariant latitude (Λ) of DE1 are shown.

Fig. 2 *a*, Retarding potential required to reduce ion count rates observed by RIMS radial head below two per accumulation period (12 ms) for a high-altitude, polar pass of DE1 on 22 October 1981. *b*, Results for field-aligned flows of H^+ , He^+ and O^+ ions. *c*, Field-aligned ion velocity ($V_{||}$) and the flux ($N_{||}V_{||}$) observed simultaneously by the IDM on DE2. Positive values are upward. Orbital tracks and model ion trajectories for this period are shown projected onto the noon-midnight meridian in *b*. The ion trajectories shown are computed for the highest and lowest energy ions of each species as observed by RIMS. Λ is the invariant latitude of the spacecraft and h is the altitude.

the locations of the satellites, projected onto the noon-midnight meridional plane in Fig. 2*b*. As DE1 moved polewards, RIMS observed first H^+ , then He^+ and finally O^+ ions at any one energy and, in addition, the peak ion energy decreased for each ion species. Hence these observations qualitatively show the predicted mass and energy dispersions. That these data are quantitatively consistent with the 'geomagnetic mass spectrometer' concept is demonstrated by the model ion trajectories also shown in Fig. 2*b*. These have been computed from the ion energies observed by RIMS using a two-dimensional kinetic model⁹ with a dawn-to-dusk electric field consistent with the IDM observations of field-perpendicular ion flow. It is assumed that the ion motion is collision free and that the electrostatic potential distribution along the geomagnetic field lines of the polar cap is as predicted for the cold polar wind⁵, as has recently been inferred from other RIMS data⁷. It can be seen that all ion trajectories converge to a narrow ionospheric source region where an exceptionally large ion upflow signature was observed by the IDM (total ion flux exceeding $10^9 \text{ cm}^{-2} \text{ s}^{-1}$). Figure 2 shows that O^+ ions were found throughout most of the dayside polar cap where RIMS data were available for this pass of DE1; other passes at high Kp (≥ 5) also reveal O^+ ions throughout the polar caps⁷.

These observations show that the narrow ionospheric source region acts as the collimation slit of the geomagnetic mass spectrometer which can disperse ions, particularly cold and heavy ions, throughout the polar cap; such O^+ ions have already been observed by both ion detectors on DE1^{10,11}. Lastly, note that these ions are present in addition to (and are warmer than) the light ions of the classical cold polar wind, which can only be observed by RIMS at these altitudes with the application of an input aperture bias potential, which overcomes the repulsive effect of the positive spacecraft potential¹².

Raman intensity measurements for determining conformer populations as a function of pressure

M. P. Dare-Edwards*, D. J. Gardiner†

Raman spectroscopy of fluids under pressure has been increasingly studied^{1,2} and applied^{3,4} over the past few years. Essential to the extension of these investigations is the reliable interpretation of the pressure-induced spectral changes of model systems in terms of variations in conformation and molecular dynamics. Conformational investigations have been made on systems that were suspected of undergoing conformational change at high pressures, for example, *n*-alkanes⁵⁻⁹, haloalkanes¹⁰⁻¹³ and substituted cyclohexanes¹⁴⁻¹⁹. Raman investigations reported here reveal significant pressure-induced spectral changes in both conformationally sensitive and insensitive systems. We suggest that these arise from a breakdown in the tenet of the pressure invariance of a direct proportionality between Raman scattering intensity and concentration. This is most apparent from the differential behaviour of symmetrical and antisymmetrical vibrations. We propose a re-evaluation of some previous interpretations of the pressure-induced spectral changes.

The vibrations of polyatomic molecules are usually discussed in terms of concerted combined motions of atoms, termed normal modes, where each normal mode forms the basis for an irreducible representation of the point symmetry group of that molecule. In general, a molecule with *n* atoms will possess $3n - 6$ normal modes or $3n - 5$ for linear molecules. Corresponding to each normal mode, a so-called normal coordinate *Q* is introduced that allows the various physical features of the molecule (such as potential energy, polarizability and dipole moment) to be represented as a function of a single length dimension.

For conformationally variant molecules, the essential assumption required for effective interpretation of the spectral changes induced by pressure is that the concentration *C* of a given conformer *r* should be directly proportional to a normalized intensity I_{rk}^{obs} for the *k*th normal mode of that conformer.

$$C_r = a_{rk} \cdot I_{rk}^{obs}$$

where a_{rk} is the proportionality constant.

For Raman spectroscopy, the intensity of an observed vibrational band is, to a first approximation, directly proportional to the derivative of the molecular polarizability (itself a second rank tensor) with respect to the normal coordinate, at the equilibrium position. Thus, for the above assumption to hold, the polarizability change corresponding to a given vibrational mode must itself be independent of pressure.

$$(\delta\alpha/\delta Q_k)_0 = \text{constant}$$

where α is the polarizability tensor, Q_k is the normal coordinate for the *k*th vibrational mode, and the subscript 0 implies the differential polarizability change at the equilibrium position.

In most investigations reported, there has been no attempt to verify the above assumption. Indeed, in the only investigation that does attempt this⁹, it is not clear that the chosen reference bands possess a sufficiently dissimilar character and symmetry to be broadly representative.

We have carried out some detailed high-pressure Raman investigations of a wide range of fluids (see Table 1). We included a comprehensive set of disubstituted cyclohexanes to allow a systematic assignment of some of the spectral features to particular conformational species. As a test of any features assigned in conformationally variant systems, for example, fluids F3, F4 and F7, comparisons were to be made with related conformationally invariant systems, for example, fluids F2, F5 and F6.

We have performed extensive tests to ensure that we have eliminated all contributions deriving from stress-induced birefringence and other optical artefacts. We used two separate Raman microscope systems, scanning and multichannel, and two different diamond anvil cells in addition to a traditional hydrostatic equilibrium cell¹⁹. In all cases, the essential observations were the same.

Fig. 1 Raman spectra of *cis*-1,4-dimethylcyclohexane: *a*, optical skeletal region; *b*, C-H, region 180° scattering, 514.5-nm excitation: ---, 0.001 kbar; —, 5.5 kbar. The numbers superimposed on the *a* spectrum are the depolarization ratios corresponding to the major peaks.

F9	Toluene d-8
F10	Cyclohexylmethanol
F11	Methyl cyclohexane carboxylate
F12	Methyl cyclopentane carboxylate
F13	Ethyl hexanoate
F14	2,4-dicyclohexyl, 2-methylpentane

Fig. 2 Raman spectra of toluene, skeletal region, 180° scattering, 514.5-nm excitation: ----, 0.001 kbar; —, 12.8 kbar.

Examples typifying our observations come from two conformationally invariant systems, notably *cis*-1,4-dimethylcyclohexane (F6) and toluene (F8). Figures 1a and 1b depict the ambient and high-pressure (5.5 kbar) Raman spectra of F6 in the optical skeletal (OS) and C-H stretching regions. The numbers superimposed on the OS spectra are the depolarization ratios corresponding to the major features. Figure 1a shows the decrease in integrated intensity of the 765 cm⁻¹ ring breathing band ($\rho = 0.02$) relative to the remaining bands with depolarization ratios in the range 0.57–0.68. In the C-H stretching region (Fig. 1b), the effect is more marked with the 2,855 cm⁻¹ symmetrical CH₂-stretching mode dramatically losing intensity relative to the antisymmetrical 2,931 cm⁻¹ band.

Figure 2 shows toluene, ambient and high-pressure spectra with the corresponding assigned depolarization ratios. Several features are apparent, most notably the loss in relative integrated intensity of the 1,004 cm⁻¹ (A_1 , $\rho = 0.07$), 1,030 cm⁻¹ (A_1 , $\rho = 0.10$) and 1,208 cm⁻¹ (A_1 , $\rho = 0.13$) bands compared with the 1,155 cm⁻¹ (B_1 , $\rho = 0.54$), 1,178 cm⁻¹ (A_1 , $\rho = 0.54$) doublet, and also the 521 cm⁻¹ (A_1 , $\rho = 0.41$) compared with the 623 cm⁻¹ (B_1 , $\rho = 0.73$) bands.

Finally, in a more complex molecule, 2,4-dicyclohexyl-2-methylpentane, originally suspected of conformational change at high pressures³, Fig. 3 illustrates the loss of intensity of the CH₂-symmetrical mode (2,850 cm⁻¹) compared with the CH₂-antisymmetrical region (2,930 cm⁻¹) with its virtual disappearance at pressures approaching 50 kbar.

These examples reveal the relationship between pressure-induced intensity reduction and the symmetry, and hence depolarization ratio, of a given Raman band. Therefore, in many instances one observes that ($I_{\text{sym}}/I_{\text{asym}}$) decreases as pressure increases. However, this effect is most marked for the C-H stretching region. Further observations may be noted for Raman bands of similar depolarization ratios but different vibrational assignments. For example, the C=C bands of a range of unsaturated ester fluids (not listed) were significantly suppressed relative to the C=O stretching bands, despite possessing similar depolarization ratios (~ 0.25).

A qualitative explanation for these observations is available in that the loss of intensity of a given vibrational band as a function of pressure is directly related to the volume change associated with that vibration. Thus, symmetrical modes, in general, and C-H stretching modes, in particular, with large associated volume changes are expected to be suppressed at elevated pressures.

Considerable attention has been given to the effect of pressure on vibrational frequencies of molecular systems. In general, the positive frequency shifts observed with increasing pressure are explained in terms of decreases in equilibrium bond lengths and consequent increases in bond force constants, related to the anharmonicity of the vibrational potential well^{20,21}. In contrast,

Fig. 3 Raman spectra of 2,4-dicyclohexyl-2-methylpentane, C-H region 180° scattering, 514.5-nm excitation. ----, 0.001 kbar; —, 17.3 kbar; - · - · -, 40.2 kbar.

very little theoretical attention has been focused on the effect of pressure on vibrational band intensities, particularly in fluids, despite the fact that it is well known that in studies of vibrations in molecular crystals symmetrical modes are suppressed relative to the liquid state and are further suppressed by pressure^{22–24}. It is apparent that as pressure induces significant changes in molecular bond lengths such as to cause appreciable force constant changes and consequent vibrational frequency shifts, the shape and slope of the polarizability/normal coordinate curves themselves must become altered. The change in $(\delta\alpha/\delta Q_k)_0$ thus induced must cause intensity changes. This will, therefore, negate the original assumption of a pressure invariance of the concentration/intensity relationship.

These observations raise additional explanations for reported pressure-induced spectral changes. As an example of one of the most thorough conformational investigations reported, one may consider the study by Wong *et al.*⁹ of the longitudinal acoustic mode (LAM) region of the Raman spectrum of *n*-hexane. Their most striking observation was of a considerable reduction in intensity of the band caused by the all-*trans* (*ttt*) conformer relative to bands resulting from the other conformers containing one or two gauche arrangements. However, the key (*ttt*) band used in the population measurement corresponds to a highly symmetrical concertina-like vibration of the molecule with a large associated molecular volume change. In contrast, the remaining bands of this LAM region, whose relative normalized intensities did not vary so significantly, correspond to vibrations of significantly lower symmetry and smaller associated volume change. Our observations on conformationally invariant systems suggest that their tenet of direct proportionality between intrinsic intensity and concentration is not upheld, particularly considering vibrations of such dissimilar symmetry and associated volume change.

Some recent infrared investigations²⁵, again including studies of some conformationally invariant systems, have revealed a similar character of spectral changes as a function of pressure to those observed by Raman spectroscopy. Assignment of the infrared bands to symmetrical and antisymmetrical vibrations is much more difficult, but notably in the C-H region where the intensity changes are most marked, the general behaviour is identical to the Raman data presented here. Thus, our main assertions have wider application to all vibrational spectroscopic studies of fluids under pressure.

¹⁰Be in ice at Vostok Antarctica during the last climatic cycle

F. Yiou*, G. M. Raisbeck*, D. Bourles*, C. Lorius† & N. I. Barkov‡

* Laboratoire René Bernas, CSNSM, 91406 Orsay, France

† Laboratoire de Glaciologie et Géophysique de l'Environnement, 38402 Grenoble, France

‡ Arctic and Antarctic Research Institute, Fontanka 34, Leningrad 191104, USSR

We have previously reported accelerator mass spectrometer measurements of the cosmogenic isotope ¹⁰Be (half life 1.5 Myr) in an 906-m ice core recovered at Dome C, Antarctica¹. In addition to an enhanced concentration during a period of reduced solar activity (Maunder minimum, AD 1645-1715)², we found substantially increased concentrations during that part of the core corresponding to the last ice age. Both effects have been confirmed and extended in Greenland ice cores^{3,4}. The recovery of a 2,083-m ice core at Vostok, Antarctica⁵, together with an extended oxygen isotope chronology reported elsewhere in this issue⁶, permits an extension of ¹⁰Be studies over the whole of the last climatic cycle (~125 kyr). We report here such measurements, which show an excellent correlation with the oxygen isotope and thus, presumably, climate record over the whole of this period. The results imply that precipitation rates in the Antarctic during the last interglacial were similar to those of the Holocene, but were roughly halved during the last glaciation.

A total of 22 samples, weighing from 0.7 to 2.0 kg, were available for the ¹⁰Be study. After the addition of 0.5 mg of ⁹Be carrier, the samples were treated as described previously¹. The ¹⁰Be measurements were made on a General Ionex Tandemron accelerator mass spectrometer system, using the procedure described elsewhere⁷. The uncertainties have been calculated using a 7% instrumental uncertainty (conservatively estimated on the basis of the reproducibility of a standard and several of the ice samples), together with 1 s.d. statistics on the number of ¹⁰Be events counted. Because we consider that the chronology of the core is still uncertain, no corrections for decay of ¹⁰Be have been made. However, using the present best estimate of the age of the ice (see below), such a correction would be <7% for the deepest sample measured. The results are shown in Fig. 1, together with the oxygen isotope profile for the same core⁶ (note that the ¹⁰Be concentration scale has been inverted to facilitate comparison with the ¹⁸O record). The correlation between the two curves is remarkable. Not only does the ¹⁰Be concentration return to Holocene levels from 1,650 to 1,875 m (believed to represent the last interglacial), but the coldest periods during the glacial, as indicated by the oxygen isotope profile, are also reflected by maxima in ¹⁰Be concentrations.

We have previously discussed three possible explanations for ¹⁰Be concentration variations in ice¹. One involves production

Fig. 1 Concentrations of ¹⁰Be (a) and $\delta^{18}\text{O}$ (b) (from ref. 6) as a function of depth in ice at Vostok. Note inverted scale for ¹⁰Be concentration to facilitate comparison of the two curves. Time scale is that adopted in ref. 6.

variations, possibly induced by solar modulation effects; the second would result from changes in atmospheric circulation; and the third links the concentration variations to changes in precipitation rates. Although we cannot yet exclude effects caused by the first two factors, the present results reinforce our belief that the third mechanism is the most probable explanation for the observed long-term correlation of ¹⁰Be with climate. Indeed, if one can neglect, or correct for, ¹⁰Be flux variations, ¹⁰Be concentrations may be used to estimate past precipitation rates^{8,9}. Such a calculation is shown in Fig. 2, using the data of Fig. 1 and assuming that the deposition flux of ¹⁰Be at Vostok has, on average, been constant over the last climatic cycle.

This interpretation of the ¹⁰Be results implies that the precipitation rate at Vostok during the last ice age was ~50% of that during the present and previous interglacial. This is consistent with results based on conductivity measurements of annual layers in the Byrd core, which indicate about a factor of 2.5 decrease going from the early Holocene to the late glacial period (C. Hammer, personal communication). It is also in partial agreement with the results of Wilson and Hendy who deduced a decrease in annual layer thickness during the late glacial period at Vostok based on sodium variations¹⁰. However those authors also found a precipitation rate larger than the Holocene value at ~900 m which is not indicated by the ¹⁰Be results. Thompson *et al.*¹¹, using annual layers derived from particle concentrations, found an approximately constant precipitation rate during the late glacial period and Holocene at Dome C. As mentioned earlier, our own ¹⁰Be results at Dome C¹ suggest about the same reduction in precipitation during the glacial period as at Vostok.

We have previously pointed out¹ that a factor of two decrease in precipitation during the late glacial period at Dome C is consistent with the hypothesis that precipitation on the Antarctic plateau has been limited by the saturated water vapour pressure above the inversion layer¹², as estimated from ¹⁸O values in the ice. That this observation also holds at Vostok can be seen in Fig. 2, where a precipitation rate based on vapour pressure⁶ is compared with that estimated from the ¹⁰Be. In fact, the agreement of the two curves indicates that the inversion temperature may have been the dominant factor in determining precipitation rates on the Antarctic plateau during the past climatic cycle. This hypothesis is the basis for the adoption by Lorius *et al.*⁶ of a model where the past accumulation rate is assumed to be correlated with temperature, as deduced from oxygen isotope analysis. Several possible explanations why ¹⁰Be may be anti-correlated with precipitation rates in polar regions are discussed in ref. 9.

The chronology that follows from a reduced accumulation rate during the glacial period, together with a flow model described in ref. 6, is shown in Fig. 1. Although this timescale

Fig. 2 Estimated precipitation rate (normalized to Holocene value) at Vostok in the past assuming a constant ^{10}Be deposition flux (solid line) and precipitation controlled by saturated water vapour pressure at temperature of inversion layer (dashed line, from ref. 6).

appears reasonable, and correlates with several other parameters⁶, it is obvious that a confirmation by direct measurement of the age of the ice at some point in the ice age is desirable. We hope to make such a measurement in the future using an accelerator mass spectrometry determination of the ^{14}C contained in the ice.

The only significant deviation between the ^{10}Be and ^{18}O curves of Fig. 1 is in the ^{10}Be measurement at 925 m. The ^{10}Be concentration in this sample is nearly 50% larger than any other, and does not correspond to the ^{18}O minimum. It is dangerous to construct any hypothesis on the basis of a single point, but it is conceivable that this sample may be showing enhanced ^{10}Be for reasons similar to that during the Maunder minimum, that is, decreased solar modulation. We plan to make more detailed measurements around this point.

In conclusion, although we do not exclude the possibility of production changes, the 'first order' cause of ^{10}Be concentration variations in Antarctic ice during the last climatic cycle seems to result from precipitation rate variations. ^{10}Be measurements may thus be a useful way of determining these precipitation rates and helping to establish chronologies. The present work suggests that the precipitation rate in the Antarctic during the last interglacial was similar to the Holocene, whereas during the ice age it was about $2 \times$ lower. The good correlation between ^{10}Be and temperatures deduced from oxygen isotopes also suggest that temperature has been the dominant factor controlling precipitation on the Antarctic plateau for at least the past ~ 150 kyr.

Deforestation in the tropics is responsible for an annual net release of carbon to the atmosphere, estimated for 1980 at between 0.5 and 4.2×10^{15} g (refs 1–6). By comparison, the release of carbon from combustion of fossil fuels was 5.2×10^{15} g in 1980. The wide range of estimates for the tropical biota and soils has been due primarily to different estimates of the rate of deforestation^{2,7}. A recent assessment of the world's tropical forests by the Food and Agriculture Organization/UN Environment Program^{8,9} provides a comprehensive, country-by-country survey of deforestation in the late 1970s as well as estimates of the volumes of wood in tropical forests. The assessment thus provides an independent data base, perhaps the most reliable to date, from which terrestrial releases of carbon to the atmosphere can be calculated. Here we compare the FAO/UNEP survey with other sources of data on rates of deforestation and stocks of carbon in the tropics; then we present the calculated net flux of carbon between tropical forests and the atmosphere based on these different data; and, finally, we consider the accuracy of current estimates of the net biotic flux.

The FAO/UNEP's^{8,9} estimate of deforestation in the tropics is compared in Table 1 with estimates made by Myers^{10–12} and the FAO's Production Yearbook¹³. Comparison of the rates given by FAO/UNEP and the Production Yearbook assumes that deforestation of the open and closed forests of the former is equivalent to the net decrease of the forests and woodlands of the latter. Because the Production Yearbooks include fallow forests in their category of forest and woodland, while

Table 1 Annual rates of deforestation of tropical forests (1975–80) according to three sources (10^6 hectare yr^{-1})

	Closed and open forests		Closed forests	
	FAO/UNEP ⁸	Production Yearbook ¹³	FAO/UNEP ⁸	Myers ^{10,11*}
America	5 391	5 430	4 119	2.67
Africa	3 678	3 089	1 333	1.57
Asia	2 005	0 895	1 815	3.27
All tropics	11 074	9 414	7 267	7.51

* About 36% of the total conversion of humid forests to agriculture and pasture was from non-fallow forests^{10,11,14}. The rest was from fallow forests, not included in this table. About 20% of the conversion of forests due to fuelwood extraction was of non-fallow forests. These 0.5×10^6 hectare yr^{-1} were divided equally among regions

FAO/UNEP does not include the deforestation of fallow, the comparison is not strictly valid. Nevertheless, it shows agreement for the entire tropics within 8% of the mean (Table 1).

Comparison of Myers' estimate with that of FAO/UNEP is only possible for closed forests, because Myers did not include dry forests or woodlands in his survey. Furthermore, Myers included the clearing of fallow as well as primary forests. The primary forests of Myers correspond to the primary, secondary, and logged forests of FAO/UNEP. His secondary forests correspond to fallow forests in the terminology of FAO/UNEP. When Myers' estimates of total conversion are partitioned between primary and secondary forests on the basis of the distribution

Table 2 The rates (10^6 hectare yr^{-1}) of conversion of fallow and non-fallow forests to permanently and temporarily cleared land; the rates are for 1980 and apply to closed forests of the humid tropics

	Non-fallow forests			Fallow forests			Total conversion
	Permanent	Temporary	Total	Permanent	Temporary	Total	
Pasture	0.7	0	0.7	1.3	0	1.3	2.0
Fuelwood	0.5	0	0.5	2.0	0	2.0	2.5
Agriculture	3.9	1.9	5.8	6.8	3.4	10.2	16.0
Total	5.1	1.9	7.0	10.1	3.4	13.5	20.5

Two and three significant figures are for clarity and consistency and do not indicate the level of accuracy. Myers¹¹ estimated that 90 and 50 million of the subsistence agriculturalists occupied fallow and non-fallow forests, respectively (Myers' terminology of primary and secondary forests is equivalent to the terminology of non-fallow and fallow forests used here). The annual rates of deforestation due to subsistence agriculture (16.0×10^6 hectare yr^{-1})¹² and to ranching (2.0×10^6 hectare yr^{-1}) were assumed to be distributed between non-fallow and fallow forests in proportion to these numbers of people. The proportions of non-fallow and fallow forests cleared as a result of fuelwood harvest (2.5×10^6 hectare yr^{-1}) were 20% and 80%, respectively¹⁴.

Table 3 Carbon in vegetation and soils of different land-use categories in the world's major tropical regions

Tropical region	Type of forest	Carbon in vegetation* (10^3 kg hectare ⁻¹)			Carbon in soils (10^3 kg hectare ⁻¹)		
		Undisturbed forest	Mature fallow	Agriculture	Undisturbed forest	Mature fallow	Agriculture
America	Moist	82 (176)	33 (70)	5	100	90	70
	Seasonal	85 (158)	34 (63)	5	100	90	70
	Dry	27 (27)	11 (11)	5	69	62	48
Africa	Moist	124 (210)	50 (84)	5	100	90	70
	Seasonal	62 (160)	25 (64)	5	100	90	70
	Dry	15 (90)	6 (36)	5	69	62	48
Asia	Moist	135 (250)	90 (90)	5	120	108	84
	Seasonal	90 (150)	50 (50)	5	80	72	56
	Dry	40 (60)	35 (35)	5	50	45	35

* Values outside parentheses are derived from volumes of growing stock^{8,9}. Values inside parentheses are based on direct measurements of carbon stocks¹⁷.

of subsistence agriculturalists^{11,14}, his rates of deforestation of primary forests agree well with the FAO/UNEP estimate for closed forests (Table 1). Agreement is within 3% of the mean for all the tropics, but within 60% of the mean for Asia. If Myers' estimates of deforestation apply strictly to tropical, moist, broad-leaved forests, his estimate is ~25% higher for the entire tropics than the FAO/UNEP estimate based on the same criteria¹⁴.

The major difference between the surveys of Myers and FAO/UNEP is not their estimates of current rates of deforestation, however, but their assumptions concerning the fate of fallow lands. The traditional form of agriculture in the tropics, shifting cultivation, has been largely replaced in recent years by a more permanent type of agriculture, referred to as "forest farming" by Myers¹⁰⁻¹² or as "sedentary shifting cultivation" by the US National Research Council (NRC)¹⁵. Even where the cultivators themselves are shifting, the land may remain permanently cleared by the arrival of new colonists or by the inability of forests to re-establish after intensive use of the land. The FAO/UNEP study, although recognizing the process, did not address the deforestation of forests that had been previously in agriculture (fallow forests) because such forests were not considered a timber resource. In the context of a carbon budget, however, the conversion of fallow forests to permanent agriculture is important because it reduces the amount of carbon stored on land. In the traditional form of shifting cultivation, the carbon released to the atmosphere on clearing is stored again during the re-establishment of forests in the fallow period. Over time, the net flux of carbon may be zero. If forests are eliminated permanently, however, the net flux is to the atmosphere.

The fraction of land cleared for agriculture that is permanent, as opposed to shifting, varies widely among regions: we estimate 66% for the tropics as a whole. This is a crude average which is based on estimates for individual countries and regions. Myers (unpublished data) estimates that the fraction of land cleared permanently may be as high as 95% in Brazil, and 90% in Columbia, Peru, Ecuador, and the Amazonian sector of Bolivia.

For all Latin America, however, an estimate of 85% was judged more appropriate because it accounts for the lower fraction of permanent conversions in Central America. In Asia, the fraction was estimated to be 70%, representative of a mean between high fractions where colonization of logged forests is common and low fractions where the more traditional shifting cultivation still predominates (for example, Papua New Guinea). In Africa, the overall average was estimated to be about 50%. It may be as low as 10% in Zaire but much higher in West Africa, especially since the drought in the Sahel has forced populations southwards into the forests. The fraction of clearing for subsistence agriculture estimated to result in the permanent clearing of forest was assumed to apply to the clearing of both fallow and non-fallow forests (Table 2).

The rates of temporary and permanent deforestation of non-fallow and fallow closed forests as derived from Myers' estimates¹⁰⁻¹² are shown in Table 2 and summarized in Fig. 1. Although Myers did not explicitly define these different pathways, the rates given in Table 2 and Fig. 1 are the only set of rates consistent with his data and with the fractions of temporary compared with permanent clearing given above. Deforestation of non-fallow closed forests (A in Fig. 1) was 7.0×10^6 hectare yr^{-1} . This rate includes the conversion of primary, secondary, and logged forests to both permanently cleared land (5.1×10^6 hectare) and to shifting cultivation (1.9×10^6 hectare yr^{-1}) (Table 2). The total is slightly lower than the one in Table 1 based on Myers' earlier estimates^{10,11}, and is close to the FAO/UNEP estimate of 7.3×10^6 hectare yr^{-1} . The breakdown between permanent and temporary deforestation differs from the FAO/UNEP estimate of 4.1×10^6 and 3.4×10^6 hectare of closed forest, respectively, but the difference between FAO/UNEP and Myers in this respect is not large.

The large difference is in their estimates of the change in fallow area. According to Myers' data 10.1×10^6 hectare of fallow forests are converted each year to permanently cleared land (Table 2). The net reduction in fallow (C-E in Fig. 1) is 8.2×10^6 hectare yr^{-1} , a reduction larger than the annual reduction in

Fig. 1 Annual rates of conversion of tropical humid forests to other uses of land (10^6 hectare) based on data from refs 10–12, 14 and Myers (personal communication)

area of non-fallow forests. The FAO/UNEP study, in contrast, estimates that the area of fallow in closed forests is increasing annually at a rate of 3.4×10^6 hectare (ref. 9). If Myers is correct, a total of 15.2×10^6 hectare of forest land is being permanently cleared each year in the tropics, with 5.1×10^6 hectare coming from non-fallow forests and 10.1×10^6 hectare coming from fallow forests that were once part of the shifting cultivation cycle (Table 2, Fig. 1).

The second place where data from the FAO/UNEP survey contrast sharply with independent evidence is in growing stocks. Evidence from several reviews of terrestrial carbon stocks^{16–18} suggests that the estimates of growing stocks reported by FAO/UNEP are low by a factor of 2 when converted to carbon stocks (Table 3).

In this analysis, the volumes of growing stock reported country-by-country by FAO/UNEP were distributed among three types of forest in each region (America, Africa, and Asia) based on the density of growing stocks⁸. Mean volumes of wood, weighted by the area deforested⁸, were determined for forest type and region (Table 3). These mean volumes were converted to carbon with factors of 0.62 for the mean density of tropical wood¹⁹, 0.45 for the carbon content of wood, and 1.72 for those parts of the vegetation not included in commercial volume, such as twigs, leaves, roots, shrubs, and trees <10 cm in diameter²⁰. Similar conversion factors were derived independently by Brown and Lugo²¹.

The forests with high, medium, and low growing stocks in each region corresponded geographically to the evergreen equatorial forests, tropical seasonal forests, and tropical dry forests/woodlands, respectively, of Olson *et al.*¹⁸ Assignment of published estimates of biomass (cited in ref. 17) to these forest types on the basis of location yielded a second estimate of the carbon stocks for these forests. These estimates were about double those derived from the FAO/UNEP study. The same result was obtained by Brown and Lugo²¹ using more forest types.

The net release of carbon to the atmosphere as a result of clearing forests for permanent crops and pasture was calculated using a model described previously for global analyses^{2,22}. Logging and fuel-wood removals were incorporated in the analyses reported here by assigning masses of carbon simulating wood products to pools that oxidized at rates of 1/1, 1/10, or 1/100 yr^{-1} . This approach is consistent with the evidence that wood removals are most often coincident with deforestation. In Asia and Africa, logged forests are frequently settled by subsistence agriculturalists^{9–11}; in tropical America logging is generally carried out in forests destined for large development projects⁹. The model was expanded in this study to include the practice of shifting cultivation. Figure 2 shows the changes in carbon stocks that accompany shifting cultivation in the moist tropical forests of Asia (Table 3).

The model was used to calculate the net flux of carbon from

Fig. 2 Changes in the carbon content of vegetation, soils and pools of dead wood during three cycles of shifting cultivation.

tropical forests according to the three estimates of deforestation and the two estimates of carbon stocks described above. The carbon stocks of vegetation at the end of the fallow cycle (mature fallow) were determined from several sources^{23–25} as were the values for the carbon content of soils^{17,26,27} (Table 3). The conversion of forests to croplands and pasture was assumed to reduce the carbon content of the forest soils by 30% and 20%, respectively^{20,26}. Analyses were made for the three regions separately.

To allow a sufficient time for cohorts of the shifting cultivation model to stabilize, all modelling analyses were started in 1940. Because the only rates of deforestation given in the FAO/UNEP survey were average rates over the 5-yr period 1976–80, different assumptions about the rates of deforestation before 1980 were examined. Such differences affected the estimated flux of carbon in 1980 by less than 10%.

The net storage of carbon in forest plantations was not calculated in this analysis but is not thought to change the net flux significantly. For the tropics as a whole, the ratio of annual planting to deforestation is about 1:10 (ref. 9). In South-east Asia where the ratio is higher, the storage of carbon due to afforestation was <5% of the total net flux²⁰.

The net flux of carbon to the atmosphere in 1980 based on the FAO/UNEP estimate of deforestation of non-fallow forests in the tropics was about 1.4×10^{15} g C with the higher estimates of carbon stocks and 0.7×10^{15} g C with the lower estimates (Table 4). The three different estimates of deforestation gave remarkably similar estimates of flux for the tropics as a whole, reflecting similarities in the rates of deforestation for the entire tropics (Table 1). Within regions, however, different estimates of deforestation generated net fluxes that varied by about a factor of two. Summing the lowest and highest estimates of flux for each region gave ranges of 0.507 – 0.826×10^{15} g C, respectively, for the lower estimates of carbon stocks and 0.982 to 1.675×10^{15} g C for the higher estimates (Table 4).

The permanent deforestation of 10.1×10^6 hectare of fallow forests (Table 2, Fig. 1) was estimated to contribute another 0.4 to 0.8×10^{15} g C to the atmosphere in 1980 depending on the stocks of carbon assumed for fallow lands. For computation of

Table 4 Calculated net release of carbon to the atmosphere in 1980 (10^{15} g) from deforestation of non-fallow forests in the tropics (Table 1)

	FAO/UNEP	Myers	FAO
America	0.344 (0.549)	0.220 (0.400)	0.419 (0.783)
Africa	0.175 (0.390)	0.184 (0.406)	0.177 (0.394)
Asia	0.198 (0.362)	0.223 (0.486)	0.112 (0.190)
All tropics	0.717 (1.401)	0.627 (1.292)	0.708 (1.367)

Values in parentheses are based on calculations with higher stocks of carbon¹⁷. Other values are based on FAO/UNEP estimates of wood volumes converted to carbon stocks as described in text.

the loss of carbon associated with the conversion of fallow forest to permanent agriculture, the carbon content of the median aged cohort in the fallow cycle, rather than that of mature fallow, was used (Fig. 2). The resolution of the data did not warrant regional analyses, and the calculation was made for the tropics as a whole. The total net release of carbon from the tropics due to deforestation was thus estimated at between 0.9 and 2.5×10^{15} g C. Uncertainties in the rate of deforestation, in the stature of forests cleared, and in the length of time forests remain cleared contribute about equally to this range.

Both the range and the magnitude of the net flux of carbon in 1980 were lower in this analysis than previously reported by Houghton *et al.*² (1.3 – 4.2×10^{15} g C). Reduction of the upper end of the range resulted from a reinterpretation of Myers' estimate of deforestation. Houghton *et al.* assumed that two-thirds of Myers^{10,11} estimate for total conversion (22.5×10^6 hectare yr^{-1}) represented permanent deforestation, as Lanly and Gillis²⁸ had found in Latin American forests. As the analysis presented here reveals, the permanent conversion of non-fallow forests to other uses of land was only 7.0 – 7.5×10^6 hectare yr^{-1} in 1980 (Tables 1 and 2).

Data from the Production Yearbooks of the FAO were also used in a different way in this study from the earlier one. Houghton *et al.*² used changes in agricultural and grazing land to derive rates of deforestation. They distributed the total increase in agricultural area between both forest and non-forest systems, so that the decrease in area of forests was less than the increase in agricultural land. However, the loss of forests and woodlands has exceeded the growth of agricultural and grazing lands, according to the Production Yearbooks, and in the analysis presented here deforestation was determined from change in the area of forests (Table 1). The excess loss of forests has been to 'other land', a fourth category given by the Production Yearbooks. 'Other land' includes many types of land, the most important of which in this context is land that has lost its capacity to support either agriculture or forest. The carbon stocks of such lands are low.

The third analysis of Houghton *et al.*² based on population growth and per capita use of agricultural land gave a flux of carbon from the tropics in 1980 (2.1×10^{15} g C) within the range presented here despite a lower rate of deforestation. The net flux of carbon was lower in the present work for several reasons. The reduction of soil carbon following clearing of forests was 30% in this analysis (Table 3); in the earlier analysis it was 50%. The lower estimate was based on a more extensive review of literature^{20,26}. The estimates of the stocks of carbon in vegetation were also lower for Latin America and Africa. The use of carbon stocks derived from the FAO/UNEP study reduced these estimates still more. Finally, the harvest of wood in this analysis was coupled with the clearing of forests for agriculture^{9,10} and, therefore, accounted for a smaller net release of carbon than in the earlier analysis where harvest was treated independently of deforestation.

The range reported here (0.9 – 2.5×10^{15} g) is higher than the ranges found in recent studies by Detwiler *et al.* (personal communication) and Molofsky *et al.*³, 0.5 – 1.8×10^{15} g C and 0.6 – 1.1×10^{15} g C, respectively. Both studies were based on models similar to the one used here and both used the same FAO/UNEP study to provide one estimate of forest biomass and one estimate of deforestation. If the deforestation of fallow lands is ignored in the analysis presented here, the ranges found by all three studies are similar.

The agreement, however, is more a reflection of the data available and the similarity of methods of analysis than a measure of how accurately the rates of deforestation or the carbon stocks of vegetation and soil are known. If the estimates of deforestation shown in Table 1 (non-fallow forests only) are assumed to represent the best estimates, agreement seems to be within about 100%, although in Asia, and India in particular, there are differences greater than 100%.

The major discrepancy between the estimates of Myers and FAO/UNEP is the direction and rate of change in area of fallow.

The size of the discrepancy is dependent on the fraction of deforestation estimated by Myers to be permanent. Lower fractions would reduce the difference and reduce the release to 0.4 – 0.8×10^{15} g C yr^{-1} calculated to result from the elimination of fallow forests. Resolution of the difference probably requires the use of extant and future data from satellites. Monitoring tropical forests with Landsat can establish rates of deforestation and whether the deforestation is permanent or temporary^{7,2}. Landsat can also be used to establish the age, and indirectly the carbon stocks, of fallow forests regrowing on lands cleared since 1972.

The difference between estimates of carbon stocks based on measurements of biomass¹⁷ and those derived from estimates of wood volumes reported by FAO/UNEP^{8,21} (Table 3) affects the range of flux estimates about as much as the uncertainty in deforestation rates. It is not clear which of the two estimates is based on samples more representative of extant forests, and whether the lower stocks of carbon are a result of natural variation or a result of disturbance by man.

The latter distinction is important because analyses here and elsewhere^{2–6} use change in the area of forests to calculate changes in the amount of carbon stored on land. Reduction of carbon stocks within areas of forest have been ignored, largely because the process of degradation is gradual and not as readily documented as deforestation. Such degradation occurs throughout the tropics, however, as a result of logging, harvest of fuelwood, deliberate burning, and grazing^{8,9}. The extent of this degradation and the net release of carbon associated with it cannot be evaluated at present; the reduction per unit area varies considerably and the areas affected are large. The direction of the net flux of carbon is clear, however. It is from land to the atmosphere. Thus the net releases of carbon from biota and soils estimated here are probably underestimates.

Submarine hydrothermal vents produce effluent plumes in the water column which can be easily detected with tracers such as ^3He , manganese and methane¹⁻³. Comparison of the tracer concentrations and temperature anomalies in such plumes with direct measurements of the pure vent waters shows that the plumes are typically mixtures of 1 part vent water with 10^4 parts ambient sea water¹. However, the extent to which hydrothermal plumes entrain and transport sea water and contribute to deep-ocean mixing is not known. We present here hydrographic data collected in the vicinity of an active hydrothermal field on the Endeavour segment of the Juan de Fuca Ridge where a well-defined effluent layer resides in the water column ~200 m above the depth of the vent field. The temperature and salinity signature of this layer indicates that a small volume of hot vent water can be very efficient at entraining ambient sea water. Directly above the Endeavour vent field, the effluent layer is composed of 0.01% vent water, 30% ambient water normally found at that depth, and ~70% entrained water which has been transported from deeper in the water column.

As shown in Fig. 1, the Endeavour segment of the Juan de Fuca Ridge is a 170-km section of mid-ocean spreading centre bounded by the Cobb Offset in the south and the Sovanco Fracture Zone in the north. In 1984, two *Alvin* submersible expeditions to this area discovered and mapped an active hydrothermal system within the axial valley of the spreading centre^{4,5}. Although the exact extent of the hydrothermal zone is unknown, a large vent field at 2,200 m depth near 47°57' N, 129°06' W was mapped in detail by *Alvin*. The field covers an area 150 × 250 m and contains many 'black smokers' venting water at temperatures up to 400 °C (refs 5, 6). The hydrographic properties in the region were mapped by vertical profiling with a Neil Brown conductivity-temperature-depth (CTD) probe, and for near-field studies the CTD was mounted directly on the submersible during several dives⁷.

The effluent layer over the Endeavour segment was discovered with the striking profiles shown in Fig. 2, which were collected in 1983, 1 yr before the existence of hydrothermal venting was

confirmed by *Alvin*. Figure 2 shows CTD profiles of temperature, salinity and potential density at TT-175, Station 6, ~4.4 km east of the vent field. For comparison, a 'background' temperature profile is shown for TT-175, Station 1, ~26 km east of the vent field. Relative to this background profile, the Station 6 profile shows a clear temperature excess of ~0.050 °C over the interval 1,960–2,140 m depth. This feature is present to some degree in all the CTD profiles collected within 5–10 km of the vent area both in 1983 and 1984, and we conclude, therefore, that this hydrothermal layer is a long-lived feature of the water column in this region. The salinity and density profiles also reveal the existence of the effluent layer: the top of the layer coincides with a pronounced hump in the salinity, and the variation of density with depth within the layer is much smaller than above or below, indicating lower stability (lower Brunt-Vaisala frequency). Note that despite the dramatic temperature excursion, the layer is nonetheless stable, that is, the water in the layer has no tendency to rise or descend.

The distinguishing features of this layer are even more apparent in property-property plots of potential temperature, salinity and potential density as shown in Fig. 3. In the north-east Pacific, these three properties form mixing lines which are almost perfectly linear for water masses sampled below ~1,000 m depth. The injection of hydrothermal vent water is one process which violates this linear mixing relationship, and the anomalous properties of the layer are exhibited as clear deviations from the linear trend. We make the reasonable assumption that the density of the layer is nearly identical to that of the water which would reside at the same depth in the absence of hydrothermal activity. Figure 3 indicates, therefore, that the layer has an excess of temperature of ~0.050 °C, and excess salinity of ~0.007‰, relative to the predicted properties for water at that density. The excess temperature and salinity of the layer exactly compensate each other to produce a mixture of the appropriate density.

The excess temperature of the layer has obviously come from the hot vent water, and suggests that vent water averaging 300 °C has been diluted by a factor of ~7,000 before reaching the layer. However, the salinity excess cannot be attributed directly to the vent water, as the salinity of the vent water would have to be >60‰ to produce the salt anomaly in the effluent layer. The pure vent water samples collected by *Alvin* at this site have salinities quite close to that of ambient sea water⁸, and CTD data collected by *Alvin* in near-field buoyant plumes show no evidence of salinities higher than ambient (see Fig. 4). Therefore, we attribute the salinity excess in the effluent layer to the entrained water which has been transported vertically by ~200 m in the water column from a region of higher ambient salinity. Using the salinity difference between bottom water in the vicinity of the vent field (2,200-m depth) and water at the depth of the layer (2,000 m), and assuming all of the entrainment occurred

Fig. 1 *a*, Map of active spreading zones in the north-east Pacific. *b*, Detailed map of study area on Endeavour segment of the Juan de Fuca Ridge, showing the location of the hydrothermal vent field (V), and the hydrographic stations (1 and 6) occupied during expedition TT-175 in 1983.

Fig. 2 a, Vertical profiles of temperature, salinity and potential density for Station 6, expedition TT-175, collected with a Neil Brown CTD in August 1983, at 47°57.5' N, 129°03.0' W, ~4.4 km east of the Endeavour hydrothermal vent field (see Fig. 1). Only the depth interval from 1,700 to 2,400 m is displayed. Potential density is expressed as σ_2 in units of % referenced to 2,000-dbar pressure. Brackets indicate the hydrothermal effluent layer which lies between 1,960 and 2,140 m depth. b, CTD temperature profile for Station 1, expedition TT-175 collected in August 1983, at 47°51.8' N, 128°47.7' W, ~26 km east of the hydrothermal vent field (Fig. 1). This serves as a 'background' profile, as it is largely unaffected by hydrothermal input.

at 2,200 m depth, we calculate that the layer must consist of 70% entrained water and only 30% water which would normally reside at 2,000 m depth. If we make the more realistic assumption that entrainment has occurred throughout the depth interval from 2,200 up to 2,000 m, then the proportion of entrained water in the layer is even higher.

Note that this entrained component cannot be detected with vent water tracers such as ^3He , and heat. Only a property such as salinity, which varies appreciably with depth in ambient sea water and has no signal in the vent fluids, can be used to estimate the extent of hydrothermal entrainment.

In addition to the stable effluent layer centred at 2,000 m depth, we were able to sample several unstable buoyant plumes with the CTD mounted on *Alvin*. One example is the ascent profile for dive 1451, shown in Fig. 4, in which the submarine passed through a plume ~0.10 °C above ambient shortly after leaving the Endeavour vent field. The potential density within this plume is lower than the overlying water, indicating that this is a buoyant water mass which is in the process of rising and entraining ambient water.

Fluid dynamical models of buoyant plumes in a stable stratified environment make predictions which can be compared with our observations. Using a buoyancy flux of $1.7 \times 10^7 \text{ cm}^4 \text{ s}^{-3}$, estimated for a single black smoker, and an ambient density

Fig. 3 Property-property plots of: a, potential temperature (θ) versus potential density (σ_2); and b, salinity versus potential density, for Station 6, expedition TT-175. The effluent layer (see Fig. 2) produces a marked excursion from the linear mixing trend which holds for ambient water masses unaffected by hydrothermal input.

gradient of $1.46 \times 10^{-6} \text{ s}^{-2}$ (Fig. 2a), the numerical model summarized by Turner⁹ predicts a maximum plume height of ~370 m and a ratio of entrained water to vent water of 3.4×10^4 at the top of the plume. Thus the model agrees roughly with our observations, which indicate a 200 m plume height and an entrainment ratio of $\sim 10^4$. The discrepancy suggests that although black smokers are the most visible type of discharge, they may not be the most typical. Thus a large fraction of the effluent layer may be a result of diffuse hydrothermal flows which individually produce buoyancy fluxes much smaller than that of a black smoker.

Stommel¹⁰ has calculated that the heat flux from hydrothermal vents should drive zonal circulation cells in the deep ocean that extend westwards from north-south trending ridges such as the East Pacific Rise and the Juan de Fuca Ridge. While Stommel assumed a plume entrainment factor of 10^3 and a plume temperature of 0.3 °C, our results indicate 10 times lower plume temperatures and 10 times more entrainment. We calculate that each calorie of hydrothermal heat should result in the vertical transport of ~25 cm³ of ambient water. A typical smoker contributes $\sim 10^7 \text{ cal s}^{-1}$, which is roughly equal to the average theoretical hydrothermal heat flux from a 1-km-long ridge segment spreading at 3 cm yr⁻¹ half rate^{11,12}. The 170-km-long Endeavour segment should introduce $2 \times 10^9 \text{ cal s}^{-1}$ and produce ~0.05 sverdrups ($5 \times 10^4 \text{ m}^3 \text{ s}^{-1}$) of vertical transport when the episodic hydrothermal activity is averaged over geological time scales. Thus the ~40 black smokers that are active at the Endeavour hydrothermal field are supplying a substantial fraction of the average hydrothermal heat flux for the 170-km long ridge segment.

The Endeavour vent field is only one of five or six active geothermal zones on the Juan de Fuca/Explorer ridge sys-

Fig. 4 Vertical profiles of temperature, salinity and potential density collected in September 1984, at the Endeavour hydrothermal vent field (see Fig. 1). The data were collected during the ascent of dive 1451 with the CTD mounted on the submersible *Alvin*. Shortly after leaving the bottom, the submarine passed through a hydrothermal plume $\sim 0.1^\circ\text{C}$ above the ambient temperature. The potential density signature shows that this was an unstable buoyant plume, quite different from the stable effluent layer shown in Figs 2 and 3.

tem^{4,5,13-17}. Applying our average hydrothermal heat flux calculation on a broader scale, the $\sim 760\text{-km}$ -long spreading system should produce ~ 0.2 sverdrups of vertical 'pumping' which, due to the considerable topography of the ridge crest, would deposit water onto several different density horizons. This transport is significant compared with the abyssal flows predicted for the deep north Pacific^{18,19}, suggesting that hydrothermal activity may influence the deep circulation patterns for a considerable distance from the Juan de Fuca Ridge axis, as predicted by Stommel¹⁰.

We thank Captain W. Clampett and the crew of the R/V T. G. Thompson for assistance during expedition TT-175, and Captain P. Howland and the crew of the R/V *Atlantis II*, Chief Pilot D. Foster, and J. Aguilar, S. Gleason and W. Sellers of the *Alvin* submersible group for help during *Alvin*/AII Expedition 112-11. G. White and J. Konecki provided the CTD, P. Morrison and K. Kröglund analysed the hydrographic data, and B. Walden, J. Aiken, R. Johnson and R. Olund interfaced the CTD to *Alvin*. C. Young and K. Thornberry attended to expedition preparations, D. Kelley, J. Karsten and A. Montgomery assisted with the hydrographic work at sea, and C. Enright and L. Nuyens helped with data processing. J. S. Turner, H. Stommel and K. C. Macdonald provided useful discussions on hydrothermal plumes. This work was supported by the Division of Ocean Sciences of the NSF.

Absolute motion and evolution of the Bouvet triple junction

Theodore G. Apotria* & Norman H. Gray

Department of Geology and Geophysics,
University of Connecticut, Storrs, Connecticut 06268, USA

* Present address: Center for Tectonophysics, Texas A&M University,
College Station, Texas 77843, USA

The absolute motion of the Bouvet triple junction has an important role in its mechanical evolution. At present, the relative velocity vectors of the South American, African and Antarctic plates form an obtuse isosceles triangle, and both the ridge-ridge-ridge (RRR) and ridge-transform-transform (RFF) configurations of the Bouvet are potentially stable. Sclater¹ demonstrated that the Bouvet twice alternated between RRR and RFF in the past 20 Myr. The reasons for these changes are unclear, but the analysis of the absolute velocities of the two configurations presented here provides some insight. The motion of the RRR configuration of the Bouvet, with respect to a hotspot reference frame, carries the junction to the north-west (343°) at 14.7 km Myr^{-1} , whereas the RFF form moves to the south-east (157°) at only 5.8 km Myr^{-1} . The RFF configuration is stable only when the relative velocity triangle is precisely isosceles. As the RFF junction migrates away from the isosceles line, it becomes increasingly unstable, until it is forced to switch to RRR. The RRR junction then drifts back to the isosceles line where it reverts to RFF.

The classic notion of triple junction stability introduced by McKenzie and Morgan² is based on constant plate velocities. McKenzie and Parker³, however, recognized that changes in relative velocities, which necessarily accompany the motion of a triple junction on the surface of the Earth, will affect its stability.

Minster and Jordan's AM1-2 absolute poles of rotation⁴ for the South American (SOAM), African (ARFC), and Antarctic (ANTA) plates, were utilized to calculate absolute plate velocities and to locate the locus of isosceles velocity triangles (Fig. 1) in the vicinity of the present Bouvet triple junction.

The actual Bouvet triple junction falls some 6° south of the calculated 'isosceles line'. This discrepancy probably reflects uncertainties in the absolute poles of the AM1-2 model because Sclater has shown that the relative velocities at the Bouvet junction form an isosceles triangle within observational error¹. To be consistent with the AM1-2 velocities, we assume here that the Bouvet triple junction is at 61.8°S ; 0°E .

Figure 2a is a velocity space diagram for the Bouvet triple junction illustrating both RRR and RFF configurations. The

Fig. 1 The position and orientation of the isosceles line in the South Atlantic calculated from Minster and Jordan's AM1-2 absolute motion model⁴. The velocity of the triple junction in RRR and RFF modes is 14.7 km Myr^{-1} at 343° and 5.8 km Myr^{-1} at 157° , respectively. In RFF mode, the junction migrates south-east away from the isosceles line becoming increasingly unstable as the velocity triangle becomes distorted. Scale bar, 20 km Myr^{-1} .

Fig. 2 *a*, A velocity-space diagram for the Bouvet triple junction with both RRR and RFF modes superimposed. In RRR mode vector, a -J1 and b -J1 are the growth rates of the SOAM-ANTA, AFRC-ANTA ridges and vector c -J1 is the rate that the SOAM-AFRC ridge is consumed. In RFF mode, vectors a -J2 and b -J2 are the rates of growth for the respective transforms, and vector c -J2 is the rate of ridge growth m is the location of the mantle reference frame. Vectors m -J1 and m -J2 are velocities of the triple junctions in RRR and RFF modes, respectively. Vector mc is the absolute velocity of the Mid-Atlantic Ridge. Two insets illustrate the direct space configurations. *b*, Changes in the shape of the relative velocity triangle which accompany the migration of a RFF junction away from the isosceles line. The rotation of the ANTA-AFRC and ANTA-SOAM vectors are much exaggerated to illustrate the fact that the original transforms become 'leaky'. Scale bar, 8 km Myr^{-1} .

RFF junction is stable only when the relative velocity triangle is isosceles. The vectors a -J2 and b -J2 are the rates of growth of the paired transforms which form when the junction is RFF. In the RRR mode, vectors a -J1 and b -J1 represent the growth rates of the SOAM-ANTA, AFRC-ANTA ridges. Vector c -J1 is the rate that the SOAM-AFRC ridge is consumed. The absolute velocities of the RRR and RFF junctions are vectors m -J1 and m -J2 respectively; m denotes the velocity of a mantle reference frame. Triple junction velocity vectors along the isosceles line are shown in Fig. 1. The Bouvet triple junction in

RRR mode has an absolute velocity of 14.7 km Myr^{-1} at 343° . When RFF, the junction migrates at 5.8 km yr^{-1} towards 157° . The orientation of these vectors change systematically along the isosceles line although they are oriented consistently in directions opposite one another.

Both the Conrad and Bouvet fracture zones are $\sim 150 \text{ km}$ in length¹. Assuming that the absolute velocities of the three plates have not changed significantly during the past 30 Myr, their rate of growth would have been 8.1 km Myr^{-1} (vectors a -J2 and b -J2, Fig. 2). This would require that the Bouvet junction remained in the RFF mode for 18.5 Myr. Using this and other information derived from the AM1-2 model, we can infer the following history for the Bouvet junction from the inception of the paired Bouvet and Conrad fracture zones.

Sometime before 31 Myr BP, a RRR version of the Bouvet junction existed south of its present location. Its absolute velocity carried it northwards at 14.7 km Myr^{-1} . At 31 Myr BP the junction intersected the isosceles line and changed to RFF mode (Fig. 3*a*). In RFF mode (Fig. 3*b*), the junction migrated with a velocity of 5.8 km Myr^{-1} at 157° away from the isosceles line until 12.5 Myr BP when it reverted to its old RRR configuration (Fig. 3*c*). During the RFF episode, the SOAM-AFRC ridge grew 120 km and both the Conrad and Bouvet transforms were generated. As RRR, the junction then drifted back towards the north-west (343°) consuming the SOAM-AFRC ridge and lengthening the SOAM-ANTA, AFRC-ANTA ridges in the process (Fig. 3*d*). Finally, 5 Myr ago, the junction arrived in the vicinity of the isosceles line (Fig. 3*e*) and switched back to RFF. Since then, the junction has been moving south-east away from the isosceles line in its present RFF configuration (Fig. 3*f*).

The inferred sequence of events is similar to the history of the junction deduced by Sclater *et al.*, from magnetic data¹. The timing of the configuration changes are, however, slightly different. Magnetics date the first RRR to RFF transition at 10 Myr BP and the second at 5 Myr BP. These discrepancies reflect either the inaccuracy of the absolute motion model or suggest that the plate motions have changed slightly during the past 30 Myr. Nonetheless, the overall agreement supports the idea that the minor changes in relative velocities which accompany junction migration can have a significant role in its evolution.

Several questions remain. For example, the RFF configuration of the Bouvet junction should be stable only on the isosceles line. Its migration away from the isosceles line would render it immediately unstable. Yet it seems to have survived for at least 18.5 Myr (31–12.5 Myr BP) in RFF mode. Why?

The reasons behind its persistence may lie in the nature of the changes in plate velocities which accompany its south-east migration (Fig. 2*b*). The rotations of the relative velocities are

Fig. 3 A model of evolution for the Bouvet triple junction based on the AM1-2 absolute motion model¹ and the length of the Bouvet and Conrad fracture zones. At the isosceles line (*a*) (31 Myr BP) the junction switched from RRR to a more geometrically stable RFF mode. As it migrated southeastwards (*b*) (20 Myr BP) the junction generated the paired Conrad and Bouvet transforms and extended the length of the Mid-Atlantic Ridge. In *c* (12.5 Myr BP), the transforms reached their final length of 150 km, and the junction switched back to RRR mode and began migrating in a northwesterly direction. As RRR (*d*), the junction drifted back towards the isosceles line. In *e*, the junction intersected the isosceles line and began generating new paired transforms until the present (*f*).

Fig. 4 Changes in the degree of geometric instability (residuals) as the RRR ($\square$) and RFF ($\triangle$) configuration of the Bouvet triple junction drifts away from the isosceles line. The orientations of the boundaries are assumed to be fixed, and spreading is assumed to be symmetrical. Instability arises because the relative velocities change with time. The RFF configuration is least affected by small changes in the velocity triangle, and it seems to be the preferred configuration in the vicinity of the isosceles line. The inset illustrates the geometric significance of the residuals.

such that the growing transforms develop a small component of extension. In other words, they become progressively 'leaky'. The actual rotations amount to only 1° over a period of 20 Myr, but this may be sufficient to make them mechanically feasible.

When the triple junction finally changes to RRR configuration, the newly generated slow spreading ridge segments must undergo rotation as the relative action vector changes during north-west migration. The MAR must also undergo a change in the spreading direction (Fig. 2b). This rotation is possibly accommodated by the generation of secondary transform faults along these ridge segments.

Questions also surround the reason why the junction switches from a RRR mode to RFF in the vicinity of the isosceles line. A partial answer may be suggested by the relative geometric instabilities of the two configurations. The location of the triple junction in two-dimensional velocity space is given by a set of three equations involving the three-plate velocities and boundary orientations. If these equations have a unique solution, the junction is stable in the sense of McKenzie and Morgan² and the velocity of the triple junction is well defined. If no solution exists, the triple junction is unstable. We suggest that the residuals of a least-squares fit in the case of an unstable junction can be used as a measure of the degree of geometric instability (see inset, Fig. 4).

For the Bouvet junction, the residuals for the RRR and RFF modes are plotted in Fig. 4 as a function of their travel time away from the isosceles line. In these calculations, the boundary orientations are fixed, and the spreading is considered to remain symmetrical. The residuals increase for RRR and RFF modes as the junction migrates. However, the instability of the RFF junction builds up much more slowly than RRR configuration. In the vicinity of the isosceles line (the origin of Fig. 4), the RFF junction is less susceptible to changes in the relative velocities perhaps explaining why it is the preferred state.

We conclude that the Bouvet triple junction is trapped in the vicinity of an isosceles line in the South Atlantic. Along this locus, the junction can exist in either RRR or RFF configuration, although RFF seems to be more stable. As the absolute motion of the RFF junction carries it away from this locus, it eventually becomes mechanically unstable and switches to a RRR configuration. The RRR junction has an absolute motion which drives it back to the isosceles line where it reverts to its original RFF configuration. Because the orientations of the absolute triple junction trajectories straddle the isosceles line, the Bouvet junction is destined to alternate between episodes of RRR and RFF as long as the absolute plate velocities remain unchanged:

Geometry of propagating continental rifts

William Bosworth

Marathon International Oil Company, Houston, Texas 77253, USA

Reconstruction of past plate configurations through palinspastic restoration of continental margins¹⁻⁴ requires a detailed knowledge of the geometries of horizontal continental extension. Extension is often restricted to discrete, linear zones termed rifts^{5,6}, and rift models that invoke propagating vertical dykes and cracks⁷⁻¹⁰ are useful for assessing the relative significance and timing of uplift, subsidence and extension in the tectonic evolution of rift basins. However, many models do not adequately account for the observed asymmetry of rifts. I describe here the general three-dimensional character of young and aborted continental rifts, which can be used to derive a structural model for the propagation of rifts in continental lithosphere. The rifts become asymmetric as a consequence of the role played by low-angle normal faults in the overall rift geometry.

Continental rifts are typically a few tens of kilometres in width, and several tens to a few hundred kilometres in length (Figs 1, 2). That these rifts are in some cases precursors to the complete rupturing of continental lithospheric plates seems to

Fig. 1 Asymmetry of continental rifts in cross-section. Rifts commonly show half-graben-like forms in cross-sections taken normal to their long axes, with most basin relief generated by a single rift bounding fault (main bounding fault, MBF), or a system of a few main faults, which are inferred to bottom out to a low-angle detachment surface. *a*, Central Graben, North Sea, section (a submerged continental rift) is an approximate depth conversion of a time section presented by Gibbs²³. *b*, Section crossing southern Gulf of Suez, constructed from industry well and seismic data. *c*, Baikal Rift, sediment thicknesses from ref. 43, but internal faulting is largely schematic. *d*, Rhine Graben, from ref. 20. *e*, White Nile Rift, in part based on the gravity work of Browne *et al.*¹⁹.

Fig. 2 Geometry of continental rifts in plan view. The major faults of continental rifts follow curvilinear patterns in map view, defining a sub-basin geometry that repeats generally every 50–150 km. Similar curvature is seen in the bounding faults of the Basin and Range Province⁴⁴. The asymmetry of the rifts in cross-section commonly reverses at each successive sub-basin, although not in every case. *a*, Gregory Rift, Kenya. Surface traces of major faults are from ref. 45. *b*, White Nile Rift, Sudan. Gravity data are from ref. 19. *c*, Suez Rift, Middle East. Surface faulting from ref. 17. Sub-basin geometry in the Gregory Rift (*a*) is more complex than portrayed here.

be well established by studies of the African–Arabian plate boundary (Red Sea and related rifts)^{11–15}. At the other extreme, continental extension may be distributed over broad zones, measuring hundreds of kilometres in each horizontal direction, as in the Basin and Range of the western United States. Whether the Basin and Range structure evolves from a few, initially discrete rifts, and whether it can eventually lead to continental breakup, are unanswered fundamental questions of continental tectonics.

Continental rifts are strongly asymmetrical in cross-sections normal to their long axis^{12,16} (Fig. 1). This asymmetry is evident in gravity-field gradients^{17–19}, relative rift shoulder elevations, sediment isopach maps^{20,21} and seismic reflection profiles^{22,23}. Meinesz²⁴ suggested that rifts would develop an initial asymmetry corresponding to the first formed bounding fault. As crustal flexure continued, the opposing fault breaks to produce a symmetrical graben form. Most models of rift formation^{8,12,25–30} have envisioned continental rifting, and hence the development of continental margins^{1,2,31} as essentially a symmetrical process at the scale of the lithospheric plate.

Many workers have suggested that the main faults of rifts pass completely through the crust to a zone of structural decoupling^{27,32,33} (Fig. 3). Recent geological and geophysical studies indicate that most of the extension within rifts and the larger Basin and Range framework is accommodated through displacement on low-angle normal faults^{22,23,24,29}. If the bounding faults of rifts link into such structures, and these fault systems cut entirely through the crust or lithosphere³⁴, then an asymmetrical rift structure would be expected. A symmetrical

arrangement of opposing low-angle detachments is untenable, as movement on one would offset the other, probably leading to the locking of one of the detachments.

Several geometries have been proposed for the detachments that are thought to underlie rifts. Wernicke³⁴ has suggested that these faults or fault zones are essentially planar on a regional scale. Alternatively, they may bottom out at a major crustal discontinuity such as the brittle–ductile transition³¹, and then plunge downwards at deep crustal ramps²³. Similarly, great diversity is observed in the internal fault patterns of rifts. Both planar fault arrays and curved (listric) fans are encountered in continental rifts^{35,36}. Differential rotation across larger rift faults, however, commonly indicates that they define a listric system. Listric faults curve in plan view as well as cross-section, but only towards the hanging wall block. Curvature towards the footwall is not kinematically viable. This effectively limits the horizontal extent of a single rift bounding fault (or system of parallel faults) to a few tens of kilometres (Fig. 2). Detailed seismic surveys reveal that rifts are typically broken into structurally-coherent compartments by transverse features^{31,37} analogous to lateral and oblique ramps in contractional tectonic settings. These structures referred to as ‘transfer faults’²³, are a syn-rift feature, although they may inherit a pre-existing structural grain.

On a larger scale, rifts also break up into sub-basins, which may form as isolated depositional systems (Fig. 2). Sub-basin boundaries may be defined by major transfer faults, pre-existing crustal discontinuities, or in some cases by younger strike-slip faults which simply offset an older rift. Significantly, rift asym-

Fig. 3 Classical rift model of a brittle upper crust deforming above a ductile zone of mechanical decoupling (after ref. 30). The principal structural form of the rift itself is that of a symmetric graben, defining a triangular wedge-block at depth.

Fig. 4 Proposed model for the propagation of continental rifts. Upper crustal extension may initiate as a broad zone of diffuse faulting (a), but quickly evolves to a system composed of a few main listric faults (and perhaps in some cases planar fault-bounded blocks³⁵) above two oppositely-directed detachments. For both detachments to remain operative, their deeper sections would need to be repeatedly recut, due to their mutually offsetting geometry. This rarely occurs, judging from the observed asymmetry of most continental rifts (Fig. 1), and one detachment locks. The active detachment propagates along the rift axis (towards the pole of opening), but curves inwards to form a large-scale scoop-like structure⁴⁴. A theoretical treatment of this fault propagation would have to consider how this entire structure evolves—both the growth of the near-surface high-angle faults and the lateral propagation of the shallow-dipping detachments. Eventually the curving, active listric system departs enough from the overall rift trend to favour a new detachment system, which links to the old at a complex area referred to by Derksen and others³⁹ as an 'accommodation zone' (AZ). Again, opposing detachments may initially form, and the advantage may go to the detachment of opposite polarity. In this case, a reversal of rift asymmetry occurs, with greater down-faulting and sedimentation adjacent to the new main bounding fault (b). Detachment systems may overlap or merge at accommodation zones in a variety of configurations, but in the plan view shown here, a cross-section normal to the rift axis at the accommodation zone would actually appear to be a symmetric graben in form³⁹. The important cross-faults in rifts referred to by Gibbs²³ as 'transfer faults' (T) are kinematically similar to accommodation zones, on a smaller scale.

metry frequently reverses at sub-basin boundaries, as was early documented for the Gulf of Suez Rift³⁸ (Fig. 2). The change in asymmetry between adjacent rift sub-basins strongly suggests that the underlying low-angle detachment system also changes polarity. The area of asymmetry reversal was first termed a "hinge zone" by Moustafa³⁸ for the associated regional dip reversal on rotated fault blocks. As asymmetry remains constant at some sub-basin boundaries, with only an offset in the rift bounding fault (Fig. 2), these major crustal structures have been more appropriately referred to as "accommodation zones"³⁹.

Young rifts, and those that failed at an early stage of continental extension, can then be thought of as large-scale half graben (mega-half graben of Cohen⁴⁰), which flip more or less regularly along the axis of the rift (Figs 1, 2). When rifting is first initiated, two opposing low-angle detachments may develop simultaneously, and propagate in the direction of the pole of opening for the two diverging continental masses (Fig. 4). One of the detachment systems soon locks, and the half-graben form develops. At some point along the incipient rift zone, the opposing detachment gains the initial advantage, and a reversal of asymmetry is forced on the bounding fault system. There appears to be some degree of regularity in this process (Fig. 2), suggesting that the lateral limits on the dimensions of listric normal faults may, in part, control the spacing of accommodation zones. Extension across the rift zone and concomitant lithospheric thinning eventually become large enough to allow complete decoupling of the two now distinct lithospheric plates and the formation of new oceanic crust. At this point, the fault systems beneath opposite sides of the rift also become isolated and develop independent fault geometries.

Recent models for the propagation of continental rifts have attempted to assess the significance of early continental extension in the development of passive continental margins, and how that extension affects plate reconstructions¹⁻⁴. Asymmetries inherent in the rift scenario described above may be reflected in the structural and stratigraphical record of rifts long after oceanic crust first appears. In particular, a geoseismic model, stratigraphical column or thermal maturation curve derived at one point on a passive margin may not accurately apply to rocks a few tens of kilometres along strike, especially with respect to the initial rift sequence. Propagating oceanic rifts^{41,42}, where rift boundaries are almost immediately structurally decoupled, and propagating continental rifts, are undoubtedly quite disparate structural phenomena.

Three distinct types of dynamic behaviour shown by a single planktonic system

William W. Murdoch & Edward McCauley

Department of Biological Sciences, University of California, Santa Barbara, California 93106, USA

A wide range of dynamic behaviour has been uncovered by studying disparate predator-prey systems¹, ranging over population stability, cycles and non-cyclic fluctuations. We know of no instance, however, in which qualitatively different dynamics have been found in the same natural predator-prey populations at different times, or in a given predator-prey system found in different but similar communities. Mathematical models of predator-prey systems, by contrast, predict that any particular system may exhibit the whole range of dynamics simply as a result of changes in rate parameters, such as those that might occur at different temperatures. Indeed, May raises the possibility that different *Daphnia*-algal dynamics in the laboratory are caused by differences in the relative values of time lags and rates of increase at different temperatures². Therefore, to produce the different dynamics, the models need not undergo any change in structure, such as might occur in different systems or groups of organisms. Here we show that field populations of a predator, the zooplanktonic herbivore *Daphnia*, and its algal prey exhibit three qualitatively different types of dynamic behaviour. This finding supports the basic premise that different dynamics can result from quantitative differences within a constant structural framework, and hence the hypothesis that variations in dynamics between systems can be explained in the same way as differences within a single system.

Populations of *Daphnia* have been raised in the laboratory under constant additions of food at fixed 2-4-day intervals³⁻⁸. These populations are strictly food-limited, their average density being a linear function of the rate of food supply³. One outcome of these studies is sustained fluctuations in density that are sufficiently regular to qualify as cycles³⁻⁶, with a period of 20-40 days. As the rate of addition of algal food is fixed and, by design, the algae cannot grow during these experiments, the oscillations are a property of *Daphnia* demography; they are single-species rather than predator-prey (or herbivore-plant) oscillations. A second outcome is damped oscillations and a third is the absence of oscillation^{7,8}.

This impressive range of dynamic behaviour in *Daphnia*, despite constant conditions and fixed food supply, led us to survey the published studies of field population dynamics of *Daphnia*, concentrating on those for which data are also available on phytoplankton fluctuations. We restrict ourselves here to discussing the dynamics of 17 studies drawn from a wide diversity of freshwater habitats⁹⁻²³, and include our own data from two experimental populations. We have excluded studies in which competition between congeneric species of *Daphnia*²⁴⁻²⁶ or fish predation²⁷⁻³⁰ appear to be important factors in the dynamics (we will examine the effects of these factors elsewhere). We have not included three examples from very cold lakes in which *Daphnia* has only about one generation a year³¹⁻³³, because the longest of these studies covers only two generations.

An implicit assumption is that the *Daphnia* and the phytoplankton populations in these different habitats have sufficiently similar biology for them to be 'structurally' similar (that is, describable by the same general model), although their parameter values no doubt differ. This is reasonable for *Daphnia* species, which are basically larger or smaller versions of a single template. The phytoplankton in any particular habitat are made up of many species, and the species composition will vary from one habitat to another. Clearly, we cannot be certain that these collections all have qualitatively similar features. The phytoplankton are more homogeneous in important features, however, than their diverse taxonomy might suggest. In most temperate

Fig. 1 An example of class 1 dynamics in which $\log_{10}$ *Daphnia pulex* Leydig abundance per m^3 and $\log_{10}$ algal biomass (mg m^{-3}) are stable. The dashed curve is a second-order seasonal trend fitted to $\log_{10}$ *Daphnia* density by least-squares regression analysis ($r^2 = 0.81$, $P < 0.001$). *Daphnia* density deviates little from this seasonal trend; the average residual deviation is $< 15\%$ of the trend value of the population. The experiment was carried out in 1,200-l stock tanks (described elsewhere⁴¹) on the campus of the University of California at Santa Barbara over a 4-month period between June and September (water temperature was 22-26 °C). These tanks represent a 'natural' habitat in the ranch country of southern California⁴². *Daphnia* populations were sampled every 3-4 days in duplicate (500-ml) samples that were counted in their entirety. Algal biomass was estimated as chlorophyll *a* and converted to cell volume.

Fig. 2 An example of class 2 dynamics in which *Daphnia* and algae appear to exhibit predator-prey oscillations. These data are from ref. 14 (Table 1). The points joined by the dashed line are the residual deviations from (logarithmic) seasonal trends and the solid line is the sine function fitted to these data (Table 1).

zone lakes, a major proportion of algal biomass is $< 75 \mu\text{m}$, of which *Daphnia* can eat those up to $50 \mu\text{m}$. Indeed, for *Daphnia*, size is a more important feature than taxonomy in distinguishing algae. Edible species vary in growth rate, and perhaps also in nutritive quality, but these variations affect parameters and not structural aspects of the model.

Visual inspection of the data suggested that populations fall into three classes. (1) Stable driven populations. Algal population density is low, with sometimes a peak in autumn in response to an increase in nutrients. *Daphnia* populations usually follow the same pattern, apparently typically being driven by the algae, which in turn are driven by slowly changing environmental factors. *Daphnia* are apparently stable, as their density tracks

A dominant feature of all natural systems is a spring peak and decline in both algae and *Daphnia*, driven by the spring increase in nutrient and light levels, and rising temperature. Our analyses covered the period following this decline. Given the observed range of periods in cycles in *Daphnia* laboratory populations, we did not look for cycles with a period shorter than 20 days; in most cases it was impossible to detect shorter periods given the frequency of sampling in the published studies. Standard time-series analysis was not possible because the data sets were too short, sampling periods were not regular and the two populations were not sampled at the same frequency. Instead, abundances were transformed to logarithms, seasonal trends where present were removed by fitting linear or second-order regressions³⁹. Populations were considered stable (no cycle present) if the average standard deviation of the logarithm of their densities was <20% of the mean logarithmic density. This percentage is a realistic estimate of sampling variability to be found in such systems, and provides an objective criterion for deciding if a population belongs to class 1. If the average standard deviation of the logarithmic residuals was greater than 20%, the residuals were subjected to Kendall and Stuart's turning point test to detect cycles⁴⁰, and sine functions were fitted using iterative nonlinear regression with parameter estimates from the turning point tests as initial values. In class 1 neither population was cyclical, except that the algae in study 12 showed a long-period seasonal cycle; in class 3 *Daphnia* cycled and algae did not. Each data set contained at least 15 sampling dates and 3 months' data after the spring decline, and almost all had more than 23 observations. Note that in studies from refs 9, 10 and 15, different classes occur in different years in the same system. NA, not applicable; NS, cycle found, not significant.

* Year in which data were collected

† Confidence limits based on the sequence of periods found in each study.

these slow seasonal changes in food supply and temperature without strong fluctuation. (2) Predator-prey cycles. *Daphnia* and phytoplankton oscillate at close to the same frequency but out of phase, in what seem to be predator-prey cycles. *Daphnia* and algae, more than most herbivore-plant systems, conform to the structure of predator-prey models in that algal individuals are small relative to *Daphnia* and are eaten whole. There is the added advantage that there is no additional basic trophic level, as in true predator-prey systems, which is only implicit in typical predator-prey models. (3) 'Single-species cycles'. *Daphnia* again oscillate, up to six times after the spring decline, but the phytoplankton appear not to oscillate even though they have a very short generation time relative to *Daphnia*. Any fluctuations in phytoplankton that do occur appear unrelated to *Daphnia* fluctuations. This pattern is similar to that observed in some laboratory populations of *Daphnia* provided with a fixed food supply, hence the title for this class.

We confirmed our subjective classification by a series of statistical analyses designed to detect cycles, estimate their period and test their statistical significance. All studies fit unambiguously into one of the three classes (Table 1). Figures 1–3 show one example from each class. Analysis of other populations might of course uncover additional classes of dynamics.

The results provide quantitative confirmation that there are distinguishable classes of population dynamics in the *Daphnia*-algal interaction, and that populations can be either cyclical or non-cyclical. The periods discovered in class 2 and 3 populations (23–47 days at average temperatures of 15–24°C) coincide closely with the range observed in cyclical laboratory populations (temperature range 14–20°C). It would have been possible to detect cycles with periods of almost 100 days in all cases and up to ~200 days in some, so the congruence with laboratory results is probably not fortuitous.

The most common behaviour was predator-prey cycles (class 2) (10 examples). There were five stable driven systems (class 1). After removal of a seasonal trend, these showed either no oscillation or one with a very long period reflecting seasonal change not captured by the simple regression (Table 1). Only two examples were of single-species cycles (class 3), although there are at least three others, for which we do not have the original data, which appear to be class 3^{34,35}.

Two important findings are that different dynamics are sometimes seen in the same lake in different years, and that different classes of dynamics are seen in the same species. The stock tank populations also showed different dynamics in the same species at the same time (Figs 1, 3).

Class 3 dynamics (in which the prey does not oscillate even though it has a very short response time and can oscillate) have not previously been demonstrated to occur in natural populations. Other systems exist in which the predator oscillates and the prey does not, or at least not on a timescale as short as that of the predator, for example, insect pests in forests³⁶ (where the pest is the predator and trees are the prey) and some disease organisms in human populations (where humans are the prey³⁷). Prey oscillations at the same frequency as those of the predator, however, are demographically impossible because of the long generation time of the prey in these situations. (In plankton, by contrast, prey generation time is measured in days, predator generation time in weeks.) The 4- and 10-yr cycles in small mammals could be the predator component of class 3 dynamics. Unfortunately, too little is known about the dynamics of the vegetation to reach a conclusion. In addition, the cycles may be internally driven by individual behaviour, and true predators of the small mammals seem to play a part in the cycles in many cases³⁸.

We cannot explain the apparent absence of oscillations in the

Fig. 3 Class 3 dynamics from tank experiment. log *Daphnia* abundance per m^3 and log *Daphnia* biomass ($mg\ m^{-3}$) oscillate, while log algal biomass ($mg\ m^{-3}$) is stable. *Daphnia* biomass (dry weight) was estimated using data on abundance and dry weights (derived from length-weight regressions⁴²). These experimental populations were run at the same time as those described in Fig 1.

algae when they are so clearly marked in the *Daphnia*. We believe the difference between algal and *Daphnia* dynamics is real, but two alternatives, based on the assumption that the difference is an artefact, need to be considered. First, the fluctuations in *Daphnia* density might be caused mainly by changes in age structure, with a roughly constant *Daphnia* biomass being maintained by the roughly constant algal biomass. Figure 3 shows that this is not the case in the one example of this class for which we have detailed information on the sizes of individuals; total biomass also cycles. Second, fluctuations might occur in the edible phytoplankton but would not be seen in the algal data (usually chlorophyll *a* concentration), which reflect the abundance of all algae, edible or not; this implies that the edible and non-edible fractions are negatively correlated in time. This explanation cannot be ruled out for all cases, but it appears not to be valid for Edmondson and Litt's study³⁴ in which the edible fraction was estimated. A third possibility is that the algae do indeed oscillate, but over such a small range that the oscillations are not detected.

Our demonstration that structurally similar systems can exhibit a broad range of dynamic behaviour suggests that it is valid to search for general models which seek to explain the variety of observed dynamic behaviour as resulting from quantitative differences contained within a common structure². In the particular system studied here, our initial hypothesis is that the existence of each broad dynamic pattern can be explained solely by the interaction between *Daphnia* and its food supply. We expect that whether class 1 or class 2 dynamics is observed in a particular lake will be determined by the manner in which factors such as nutrient levels and average temperature influence ecological properties (such as algal rate of increase) of the populations. We are now testing this hypothesis.

Light-dependent antibody labelling of photoreceptors

Grant W. Balkema & Ursula C. Dräger

Department of Neurobiology, Harvard Medical School, Boston, Massachusetts 02115, USA

Monoclonal antibodies are tools widely used to analyse the structure of the nervous system. Whereas some labelling patterns are highly reproducible, others appear to vary from one preparation to the next, as we noticed in particular for some antibodies with respect to photoreceptor labelling. To establish whether some of this variability can be linked to functional criteria, we tested for light-dependence. We found two antibodies that label photoreceptor outer segments, only when the retina has been illuminated, and a third antibody that has a selective affinity for dark-adapted outer segments. The two antibodies against light-activated sites are primarily directed against the highly phosphorylated neurofilament subunit at relative molecular mass 200,000 (200K). One of them RT97, recognizes on immunoblots, in addition to neurofilaments, a light-activated epitope on a protein that resembles the photopigment rhodopsin, presumably a phosphorylation-dependent site. Antibodies like those described here may allow the study of physiological processes such as light and dark adaptation using morphological techniques.

As many physiological events in the nervous system are executed through reversible covalent modifications in molecules, it should be possible to find antibodies selective for particular states of the sites that undergo changes. We found previously that antibodies against the heavy (200K) neurofilament subunit can reveal neuronal reactions to injury; these changes were inducible over a time course of days¹. Some of the same antibodies detect modifications in mitotic cells which appear and vanish within about 1 h (ref. 2). Our studies revealed that two

Fig. 1 Transverse sections through dark-adapted (left vertical lane) and light-adapted (right lane) retinas labelled with the antibodies R3 (ref. 4) (top row), RT97 (ref. 3) (middle) and B16 (ref. 6) (bottom). The layer of photoreceptor processes, including inner and outer segments, are indicated by the arrows on the left and right margins; other retinal layers are labelled as: onl, outer nuclear layer; opl, outer plexiform layer; inl, inner nuclear layer; ipl, inner plexiform layer; gcl, ganglion cell layer. Note that the two neurofilament antibodies RT97 and R3 label photoreceptor outer segments only in the light-adapted condition; the labelling of neurofilaments in horizontal cells and optic axons is independent of the illumination history. Antibody B16 has selective affinity for dark-adapted outer segments. Scale bar, 50 μ m.

neurofilament antibodies of the same class, and another unrelated antibody, can be used to detect changes that occur within seconds to minutes in photoreceptor outer segments in response to light and darkness.

C57BL/6J mice were anaesthetized with pentobarbital, their body temperature was maintained at 36.5 °C, and they were dark adapted for 45 min; one eye was taped shut and the other was either diffusely illuminated or was covered with a contact lens and exposed to stationary visual patterns. After ~2–8 min, the mice were quickly perfused under dim red light with 4% paraformaldehyde/0.12% picric acid; the retinas were left as whole mounts or sectioned on a cryostat and processed for indirect immunofluorescence, using fluorescein-isothiocyanate labelled secondary antibodies (Boehringer Mannheim). Of 10 different monoclonal antibodies against 200K neurofilaments that we tested, only two showed light-dependent photoreceptor labelling: the antibodies RT97 (ref. 3) and R3 (ref. 4). The third antibody described here, B16, was generated following the protocol of Matthew and Patterson⁵ in a fusion aimed at obtaining antibodies against photoreceptors⁶: a BALB/c mouse was first immunized with mutant retina lacking photoreceptors (C57BL/6J *le-rd*), then many of the responding B cells were eliminated by intraperitoneal injection of cyclophosphamide, and finally the surviving B cells were challenged *in vitro* with

retina from normal mouse (C57BL/6J), and fused with NS1 myeloma cells⁷.

Figure 1 shows sections from dark-adapted (left) and illuminated retinas (right) labelled with these three antibodies. The antibodies RT97 and R3 reveal the characteristic neurofilament distribution which is, as expected, independent of illumination levels: these are components of horizontal, ganglion and amacrine cells. The photoreceptor outer segments, however, are labelled only in the illuminated retinas and negative in the dark-adapted ones. As there are no neurofilaments in outer segments, the light-activated labelling must reflect a chance cross-reactivity. The third antibody, B16, shows the reverse pattern with respect to the outer segments: it labels them only in the dark-adapted state. In addition this antibody labels synaptic components with high affinity and all cell nuclei with low affinity, regardless of the illumination history. All three antibodies appear to label only the outer segments of rods and not of cones, as we determined by double-labelling with cone-specific peanut lectin⁸ (data not shown).

The labelling is spatially precise: if the mouse had been viewing a striped pattern, the retina is labelled in a striped fashion, as shown for RT97 in a whole mount in Fig. 2a. If the mouse was held stationary during visual stimulation the stripes are interrupted by the shadows of the blood vessels in the inner retina (Fig. 2b). To illustrate the complementarity of labelling with the two types of antibodies, we let the mice face writing in bright letters: a retinal whole mount from such a mouse labelled with RT97 shows the writing as bright on dark (Fig. 2c), and in a B16-labelled retina the writing appears dark on a bright background (Fig. 2d).

Although both neurofilament antibodies label outer segments only in the light, they seem to recognize different antigenic sites, as indicated by light-adaptation experiments: anaesthetized mice were exposed to a brightly illuminated screen in the nasal half of their visual field with the temporal half blocked off by a black mask; after 10 min the mask was quickly pulled away to allow for short periods of full-field stimulation. The mice were then rapidly perfused under dim red light, the retinas sectioned dorsally to ventrally and examined for temporo-nasal differences in photoreceptor labelling. Such light-adaptation experiments revealed traces of the RT97 site within as little as 10 s of light exposure; over the following minutes the labelling intensity increased up to a maximum and thereafter remained constant. The R3 site behaved differently: like the RT97 site it turned on rather rapidly in response to light onset and grew to a maximum; however, it then diminished with steady illumination. This is illustrated in Fig. 3 for a mouse whose nasal retina (right) was illuminated for 10 min and 45 s, and the temporal retina (left) for 45 s only: RT97 labels the 45 s exposure less brightly than the 10 min + 45 s exposure, whereas R3 shows the reverse pattern: the retina half illuminated for 45 s is brighter. Hence under the intense illumination conditions used here the R3 site appears to respond preferentially to light transients, whereas the RT97 site seems to measure the amount of illumination.

We tried to determine the relative molecular masses of the illumination-dependent antigens. C57BL/6J mice were light- or dark-adapted for 1 h; their retinas were removed under bright white or dim red light, homogenized and dissolved in cold SDS, separated on SDS/polyacrylamide gels and blotted onto nitrocellulose paper^{9,10}. So far we have found a clear light/dark difference on blots only for RT97, as shown in Fig. 4a, which compares RT97 with the monoclonal antibody RET-P1 that recognizes rhodopsin¹²; the lanes of dark-adapted retinas (D) were loaded with twice the amount of protein as the lanes of the light-adapted preparation (L) to bias against detection of light-activated antigens. RET-P1 labels both in the light- and dark-adapted preparations three broad regions which presumably correspond to rhodopsin and its aggregates; the broad distributions reflect multiple bands that probably differ in phosphorylation states. RT97 reacts practically only with the light-adapted preparation; it recognizes mainly a broad region at

Fig. 2 Whole mounts of retinas from mice exposed to stationary visual patterns for ~8 min, and reacted with RT97 (*a-c*) and B16 (*d*). The mouse of the retina in *a* had been viewing a flat panel with parallel stripes covering most of the visual field through the stimulated eye. The labelling pattern reflects a combination of tangent and spherical distortions. In a higher power view of a different retina (*b*) a stripe, composed of labelled rod outer segments, can be seen disrupted by the shadows of blood vessels from the inner retina, indicating that the mouse did not move during visual stimulation. What at this magnification appears as slight irregularities in outer segment labelling corresponds at higher magnifications to cross-striations within single outer segments: apparently, stacks of disks partially separated because of mild detergent treatment of the whole mounts. Single labelled outer segments are visible here, because they are surrounded by unlabelled ones, which seems to reflect the mode of dark adaptation of the RT97 sites; with increasing time in the dark after a strong light stimulus, increasing numbers of outer segments lose RT97 affinity in an all-or-none fashion. The mice in *c* and *d* were exposed to the same

bright writing on a dark background: RT97 recognizes the illuminated letters and B16 the dark background. Under the gentle conditions of antibody incubation used here, RT97 did not penetrate sufficiently into the tissue to label neurofilaments except around the optic disk and at the edges of the whole mounts. Scale bars, 1 mm (*a, c, d*) and 200 μ m (*b*).

33–39K and a weaker one at 67–76K, both of which line up roughly with the two lower regions of RET-P1. In other preparations a third band just above 100K, at the approximate location of rhodopsin trimers, was very weakly labelled in a light-dependent fashion. In preparations aimed at minimizing rhodopsin aggregation (Fig. 4*b*), RT97 recognized a single light-induced band at 34–40K, in addition to light-independent bands that correspond to the 200K neurofilament subunit and its presumed breakdown products¹¹. A plausible explanation is that RT97 crossreacts with light-adapted rhodopsin; if this assumption is correct, the apparently higher affinity of RT97 for rhodopsin monomers than for aggregates, compared with RET-P1, may indicate either that the RT97 site interferes with rhodopsin aggregation or that it is less accessible in aggregates.

We do not yet know what the changes at the three illumination-dependent sites may be, but a cue to the nature of two of them comes from the affinity of the antibodies for 200K neurofilaments. This neurofilament subunit is known to be highly phosphorylated, and most 200K neurofilament antibodies were shown to label neurofilaments in a phosphorylation-dependent manner^{13–15}; they presumably recognize either a short peptide

sequence containing a phosphoserine, or a change brought about in the peptide chain by nearby phosphorylation. A phosphorylation dependent labelling applies also to the two antibodies RT97 and R3 used here: their affinity for neurofilaments can be abolished by alkaline phosphatase treatment (J. Wood, personal communication); we observed the same for isolated outer segment preparations (data not shown). A major covalent modification in photobleached rhodopsin is phosphorylation at a total of nine sites, a process thought to impede its ability to participate in the phosphodiesterase activation cycle and considered a mechanism in light adaptation^{16–19}. For RT97 a crossreactivity with one of the light-induced phosphorylation sites on rhodopsin appears likely. R3 may also cross-react with rhodopsin (although so far we could not detect such a cross-reactivity on blots) or it may recognize one of several other outer segment proteins that are phosphorylated in the light²⁰. The light-adaptation experiments indicate that the R3 site probably differs from the RT97 site and that the two sites may mediate different functions. As activation of the RT97 site increases with illumination time up to a saturated level, its behaviour is consistent with a mechanism involved in the mediation of light adaptation. The R3 site,

Fig. 3 Light-adaptation experiment. Transverse sections from retina exposed to bright light for 10 min in its nasal half only, and for 10 min and an additional 45 s to full-field stimulation. The border between the nasal (N) and temporal (T) halves is indicated by the white lines above the sections. Note that RT97 labels the 10 min + 45 s exposure more brightly than the 45 s exposure, whereas the R3 labelling is brighter after the shorter stimulation period. Scale bar, 200 μ m.

on the other hand, does not seem suited to mediate light adaptation, as it seems to adapt to light by itself. Alternatively, the apparent light adaptation of the R3 site may be an artefact resulting from steric hindrance of antibody binding through neighbouring additional phosphorylation sites. Finally, we have no clue to the antigen(s) recognized by antibody B16 in photoreceptors. If labelling with B16 were also related to phosphorylation events, it may be directed against one of the components in photoreceptor outer segments that are phosphorylated in the dark in a cyclic GMP-dependent manner, or it may recognize a site that is unmasked by dephosphorylation in the dark^{21,22}.

Fig. 4 *a*, Immunoblot of RT97 (ref. 3) on light- and dark-adapted retinas and comparison with RET-P1, a monoclonal antibody recognizing rhodopsin¹². Mice were either light-adapted (>100 cd m⁻²) or dark-adapted for 1 h, and killed by cervical dislocation. Retinas were quickly removed, homogenized in a buffer containing 1 mM EDTA, EGTA and phenylmethylsulphonyl fluoride, and treated with DNase (1 mg ml⁻¹). Samples were dissolved in cold sample buffer to a final concentration of 2% SDS, 5% 2-mercaptoethanol, 10% glycerol, 0.01% bromphenol blue in 0.625 M Tris HCl, pH 6.8, briefly sonicated (not boiled) and loaded onto a 12% polyacrylamide gel: 100 µg protein from dark-adapted retinas per D-lane, and 50 µg from light-adapted retinas per L-lane. Electrophoresis was performed using the buffer system of Laemmli⁹, and proteins were transferred from the gel onto nitrocellulose paper according to Towbin *et al.*¹⁰. Strips of nitrocellulose paper were either stained for protein with amido black, or blocked with 3% bovine serum albumin and processed for antibody binding using peroxidase labelled secondary antibody (Cappel) and 3,3',4,4'-biphenyl tetramine tetrahydrochloride (Sigma) as chromogen. Relative molecular mass standards were myosin (200K), phosphorylase B (97K), bovine serum albumin (68K), ovalbumin (43K) and α -chymotrypsinogen (26K). Note that RT97 recognizes two broad regions in the light-adapted lane that line up roughly with the presumed monomers and dimers of rhodopsin labelled by RET-P1. Apparent relative molecular masses of the labelled regions, as determined from this and four other gels, were 33–39K (s.d. 3) and 67–76K (s.d. 8) for RT97, in addition to a very faint band just above 100K, and 32–38K (s.d. 3), 67–78K (s.d. 7) and 103–109K (s.d. 1) for RET-P1. *b*, Light- and dark-adapted retinas blotted with RT97, prepared slightly differently to minimize rhodopsin aggregation and to demonstrate neurofilament labelling: one retina per lane was homogenized in 50 µl pH 7.4 Tris buffer containing 1 mM EDTA and 0.1 µl saturated phenylmethylsulphonyl fluoride, and incubated for 10 min with 0.017% sodium deoxycholate; the protein was precipitated by adding 6 µl of 72% trichloroacetic acid and the precipitate was resuspended in SDS sample buffer⁹ by sonication and vortexing, and treated as above. The light-independent bands are the same as seen by Calvert and Anderton¹¹ on blots of rat brain with RT97: the 200K neurofilament subunit and presumed neurofilament breakdown products.

We have shown here that monoclonal antibodies can be used to detect relatively fast physiological changes in photoreceptors. Such antibodies may allow the analysis of reversible covalent modifications at single sites, which at least for the phosphorylation sites on rhodopsin has not been possible with conventional biochemical techniques. As many physiological changes are brought about by phosphorylation events²³, the group of 200K neurofilament antibodies may provide a reservoir of detectors for functional epitopes.

We thank Dr J. Wood for antibody RT97, Drs V. Lee and L. Sternberger for the gift of neurofilament antibodies, Dr C. Barnstable for antibody RET-P1, Dr W. Matthew for advising us about the differential immunization technique, Drs P. Hogan and H. Kühn for helpful comments, S. Edelstein for technical assistance and J. Gagliardi for photography. This work was supported by NIH grants EY 01938 and 05019, and by a grant from the American Federation for Aging Research.

Stimulation of multipotential, erythroid and other murine haematopoietic progenitor cells by adherent cell lines in the absence of detectable multi-CSF (IL-3)

C. L. Li & G. R. Johnson

Developmental Haematopoiesis, Walter and Eliza Hall Institute of Medical Research, Royal Melbourne Hospital, PO Victoria 3050, Australia

It is well established that murine multipotential and committed erythroid progenitor cells require the presence of a glycoprotein, termed multi-CSF (multi-colony-stimulating factor, IL-3)^{1–7} for clonal proliferation and differentiation *in vitro*. The initial proliferation of these cells can also be stimulated by two other glycoproteins, granulocyte-macrophage CSF (GM-CSF) and granulocyte CSF (G-CSF), although continued proliferation and differentiation requires the subsequent presence of multi-CSF^{8,9}. Here we report the stimulation of multipotential, erythroid and other haematopoietic progenitor cells by a number of adherent cell lines including a cloned bone marrow cell line (B.Ad). The positive cell lines, as feeder layers, exhibit colony-stimulating, erythropoietin-like and burst-promoting (BPA) activities. Optimal erythropoietic stimulation by the B.Ad line requires close cell–cell contact. The cell lines also support the *in vitro* clonal growth of multipotential colony-forming cells and progenitors of six other haematopoietic lineages. The biological activities observed seem not to be mediated by known multipotential or erythroid colony-stimulating factors (multi-CSF⁷, IL-3⁵, MCGF¹⁰, HCGF³, PSF⁶, BPA²).

Fig. 1 Phase contrast photograph showing confluent cultures of B.Ad cells. Note clusters of polygonal cells heavily laden with lipid droplets. $\times 135$. The cell line was isolated from a non-adherent cell population taken from a 1-week-old liquid culture of BALB/c bone marrow cells. It was observed during weekly serial passages of the non-adherent expanding population of mast cells in growth medium (DMEM containing 20% fetal calf serum, supplemented with medium conditioned by WEHI-3B myelomonocytic leukaemic cells (WEHI-3B CM)), that there were always adherent cells growing in the cultures. On reaching confluency, cells heavily laden with lipid droplets appeared. Nine months after initiation of the cultures, non-adherent cells were removed and adherent cells collected by trypsinization and cultured alone. This cell line has been designated B.Ad (BALB/c adherent) and has now been maintained as adherent cultures for >1 yr.

B.Ad cells were derived from BALB/c bone marrow adherent cell cultures (see Fig. 1 legend). On reaching confluence, cultures of B.Ad cells displayed clusters of lipid-containing cells intermixed with fibroblastoid cells (Fig. 1). The lipid-containing cells were oil red O positive, and most cells showed weak nonspecific esterase activity, but no metachromasia, myeloperoxidase or acetylcholinesterase activity. Approximately 95% of the cells phagocytosed latex particles and had the following surface phenotype: $H-2^+$ (40–60%), Ia^- , Ig^- , Lyl^-2^- . The mean population doubling time was 76 h and the cells had a modal chromosome number of 75. Tests for tumorigenicity are in progress,

but no tumours are evident 2 months after subcutaneous inoculation of 10^6 B.Ad cells into syngeneic newborn mice.

Table 1 shows colony formation by bone marrow cells separated from the adherent layer of B.Ad cells by an intermediate layer of agar medium. Most colonies were composed of neutrophils and/or macrophages but megakaryocytes and mixed cell colonies were also observed (average of 4 per culture), although less colonies were stimulated by the B.Ad cells than in control cultures stimulated with PWM-SCM (pokeweed mitogen-stimulated murine spleen cell-conditioned medium).

The erythropoietic stimulating activity of B.Ad cells was investigated using methylcellulose cultures which allow target fetal liver cells to seed directly on top of the feeder layers. Table 2 shows the result of a typical experiment. In the absence of exogenous erythropoietin, B.Ad cells supported the growth of late erythroid (day 2 colony forming units-erythroid (CFU-E)) colonies (Table 2). Separation of fetal liver and B.Ad cells by an agar interlayer reduced the number of CFU-E colonies by 75%. Mixing experiments with either PWM-SCM or erythropoietin showed that there was no significant inhibitory or additive effect by the B.Ad cells on the growth of CFU-E colonies. When examined at day 7, small multicentric foci of poorly haemoglobinized erythroid cells were observed. In sharp contrast, in the presence of exogenously added erythropoietin, the B.Ad cells could stimulate about fourfold higher numbers of erythroid colonies which were larger and more haemoglobinized than in cultures maximally stimulated by PWM-SCM + erythropoietin. There was no significant difference observed in the number of non-erythroid colonies.

Following sequential removal, smearing and staining of all colonies in cultures of 2×10^3 fetal liver cells, pure erythroid, neutrophil, neutrophil-macrophage, neutrophil-macrophage-mast cell, neutrophil-macrophage-eosinophil and erythroid-neutrophil-macrophage-eosinophil-mast cell-megakaryocyte-blast cell colonies were observed.

The fetal liver origin of the macroscopic erythroid colonies was confirmed by the presence of a single adult haemoglobin band ($\alpha_2\beta_2$ major) characteristic of C57BL/6 mice, when C57BL/6/f/J WEHI fetal liver cells were seeded onto the B.Ad cell line.

Separation of the target cells from the adherent cells by an agar interlayer reduced the number of macroscopic erythroid colonies by $>90\%$ but did not significantly affect the number of non-erythroid colonies. In cultures containing both B.Ad cells and PWM-SCM the same high numbers of erythroid colonies developed as with B.Ad cells alone, suggesting that no inhibitors

50,000 CBA/CaH bone marrow cells were seeded into 35-mm Petri dishes containing 1 ml 0.3% agar in Dulbecco's modified Eagle's medium (DMEM) supplemented with 20% fetal calf serum (FCS). Cultures were kept in a fully humidified 37 °C incubator containing 10% CO₂ in air. Cultures were scored after 7 days of incubation and were then fixed with 2.5% phosphate-buffered glutaraldehyde at room temperature overnight. Whole culture mounts were prepared and stained sequentially with cholinesterase stain, Luxol-fast-blue stain and counterstained with Meyer's haematoxylin. Colonies were typed according to criteria described previously¹⁶.

* PWM-SCM was prepared from BALB/c spleen cells as described previously¹⁷; 0.1 ml of pre-determined dilution of PWM-SCM (giving maximal stimulation) was used.

† Monolayers of B.Ad cells were prepared in 35-mm Petri dishes by splitting confluent stock cultures 1:100 and seeding cells in 1 ml medium. On reaching confluency (10–14 days), culture medium was removed and 0.5 ml 0.3% agar medium was laid on top of the cell monolayer. After gelling, 1 ml of agar medium containing bone marrow cells was overlaid and allowed to gel before incubation.

‡ Triplicate counts (means $\pm$ s.d.).

§ Results were the average of triplicate plates.

|| Mixed-cell colonies containing neutrophils, macrophages, either eosinophils or megakaryocytes or both with the apparent absence of recognizable erythroid cells.

Clone 7 (A)	72	0	55	948	7	70

Adherent layers of B.Ad cells were prepared as described in Table 1; 10,000 12-day CBA/CaH fetal liver cells were cultured in 35-mm Petri dishes in 1 ml volume of 0.78% methylcellulose (Methocel MC, premium, 4,000 cP, Dow) in Iscove's modified Dulbecco's medium containing 20% fetal calf serum and 7.5×10^{-5} M 2-mercaptoethanol. Cultures were kept in a fully humidified incubator at 37 °C with 5% CO₂ in air. CFU-E colonies were scored on day 2 and both erythroid and non-erythroid colonies were scored on day 7. Erythropoietin (Epo) was partially purified from human urine and has been shown to be free of CSF activity. 0.1 ml of predetermined dilution of erythropoietin (giving optimal stimulation of CBA fetal liver CFU-E colonies) was used. ND, not determined, or not scored.

* MLCM, mouse lung conditioned medium, was prepared as described previously¹⁸, 0.1 ml of pre-determined dilution of MLCM (giving maximal stimulation of colony growth by bone marrow cells) was used.

† A 0.5 ml, 0.3% agar-medium, interlayer was laid on top of the B.Ad feeder layers before methylcellulose medium containing target cells was plated. The presence of an interlayer neither inhibited nor enhanced colony formation in control cultures stimulated with PWM-SCM.

‡ B.Ad cells were cloned either by limit dilution method in 96-well tissue culture plates (at a density of 0.4 cells per well in 0.2 ml growth medium) or by single-cell manipulation of B.Ad cells in the log phase of growth. In the latter method, diluted cell suspensions of B.Ad cells were prepared and seeded into 15-cm Petri dishes containing pieces of coverslips. After 1 h of incubation, coverslips with single cells or doublets were located under an inverted microscope and were individually removed and transferred to 12-well tissue culture plates or 35-mm Petri dishes for clonal expansion. A total of 12 subclones was successfully derived.

§ In the absence of erythropoietin, degenerating erythroid colonies are included in the non-erythroid category. In the presence of erythropoietin degenerating erythroid colonies were rarely observed. The apparent increase in non-erythroid colony numbers after inclusion of agar interlayer reflects difficulty in distinguishing non-erythroid colonies intermixed with B.Ad cells in cultures without agar interlayer.

were present in PWM-SCM preventing colony formation by the erythroid progenitors.

Several clones of the B.Ad cell line were isolated and all exhibited biological activities similar to those associated with the parental uncloned line (Table 2).

To determine whether the observed biological activities could be attributed to multi-CSF⁷ (IL-3), we investigated whether feeder layers of B.Ad cells could support colony formation by the multi-CSF-dependent cell line, 32D cl.3 (ref. 11). It was observed that the B.Ad cells could neither support the clonal growth in semi-solid cultures (Table 3) nor the survival of 32D cells in liquid co-cultures. Furthermore, prolonged incubation of haematopoietic cells (either bone marrow or spleen) with B.Ad cells for up to 4 weeks did not result in the generation of suspension cultures of mast cells.

We next investigated whether medium conditioned by B.Ad cells or B.Ad cells and fetal liver cells contained the biological activities described previously. Even after 18-fold concentration, we could not detect erythroid, megakaryocyte, mixed cell or 32D cl.3 colony stimulating activity in the conditioned medium, although macrophage and to a lesser degree, neutrophil colonies were stimulated in agar cultures of bone marrow cells. However, when conditioned medium was added to liquid cultures for 7 days containing 3-day post-5-fluorouracil-treated bone marrow

cells, generation of multipotential and progenitor cells occurred. The latter were assayed in agar cultures containing PWM-SCM and were present at three- to fourfold higher numbers in liquid cultures containing B.Ad conditioned medium than control liquid cultures containing PWM-SCM. No cells were detected in liquid cultures containing mouse lung conditioned medium as a source of GM-CSF.

The erythroid potentiating activity of the B.Ad cells was compared with five other adherent cell lines (Table 4). Three of these lines supported day 7 erythroid colony formation in the presence of erythropoietin and two were not active in this assay. A sixth cell line (NIH 3T3) did not support day-7 erythroid colony formation, although its growth was variable in the presence of the fetal calf serum required for erythroid colony growth. None of these cell lines produced detectable multi-CSF when assayed with 32D cells, but one (Swiss 3T3) stimulated a GM-CSF-, multi-CSF-dependent cell line, suggesting the presence of GM-CSF.

The present experiments suggest that the erythroid colony stimulating activity associated with the B.Ad cells was not mediated by multi-CSF and unlikely to result from GM-CSF. Evidence against the former comes from lack of stimulation of 32D cl.3 cells, and the fourfold increase in erythroid colonies (compared with PWM-SCM-stimulated controls) and presence of megakaryocyte colonies would not be expected with GM-CSF¹². The results suggest the presence of a new as yet unidentified factor having the biological effects observed. The ability of B.Ad conditioned media to stimulate haematopoietic cell generation in liquid cultures of 5-fluorouracil-treated bone marrow cells may provide a convenient method to assay this factor. A similar conclusion has been made recently using conditioned media from a number of uncloned bone marrow cell lines, or a human bladder carcinoma cell line^{14,15}.

Another possible explanation for the unexpected range of colony stimulating activities expressed by the B.Ad cells could be via stimulation of accessory cells present in the fetal liver target cell population. However, identical results have been obtained using uncloned and cloned B.Ad cells with purified populations¹³ of fetal liver progenitor cells (data not shown) and no appropriate activity was detected in medium conditioned by mixtures of B.Ad and fetal liver cells.

The present experiments also suggest that there is an additional population of erythroid progenitor cells present in fetal liver that cannot be stimulated by multi-CSF and that the stimulation is more effective if target cells and adherent cells are in close contact.

The ability of several other cell lines to stimulate day 7 erythroid colony formation in the apparent absence of multi-CSF requires further investigation. The fact that several cell lines were inactive suggests that the erythroid effect is not caused by improvement of culture conditions by some general metabolic

effect. However, the positive cell lines should provide a convenient source of conditioned media to aid identification of the proposed new factor(s) producing the reported biological effects.

We thank Mrs J. Boyd and Mr R. L. Cutler for the preparation of human urinary erythropoietin, Miss S. Pappas for performing electrophoretic analysis of haemoglobins and Dr D. Metcalf for critical reading of the manuscript. Nonrandom loss of chromosome 15 in Syrian hamster tumours induced by v-Ha-ras plus v-myc oncogenes

Mitsuo Oshimura, Tona M. Gilmer & J. Carl Barrett

Environmental Carcinogenesis Group, Laboratory of Pulmonary Pathobiology, National Institute of Environmental Health Sciences, PO Box 12233, Research Triangle Park, North Carolina 27709, USA

Nonrandom chromosome rearrangements, observed in a variety of human and animal tumours^{1,2}, are associated in some cases with enhanced expression or deregulation of cellular oncogenes^{3,4}. Recently, it was shown that normal, diploid rodent cells are neoplastically transformed following transfection with two cooperating oncogenes, for example *myc* plus *ras*⁵⁻⁷. However, the number of steps necessary to convert a normal cell into a malignant cell is unknown. If activation of two oncogenes is sufficient for tumorigenicity, tumours derived from diploid cells transformed by the transfected oncogenes may remain diploid or have only random chromosome alterations. We have performed cytogenetic analyses of tumours formed after transfection of Syrian hamster embryo cells with either v-Ha-ras plus v-myc DNAs or polyoma DNA alone. Whereas polyoma-induced, tumour-derived cells were diploid, tumours induced by v-Ha-ras plus v-myc oncogenes were monoclonal and had a nonrandom chromosome change, monosomy of chromosome 15. Thus, an additional change, loss of chromosome 15, is required for or is advantageous for tumorigenicity induced by v-Ha-ras plus v-myc oncogenes. These results suggest that the neoplastic progression of normal, diploid cells requires more than two steps under certain conditions.

Early passage Syrian hamster embryo cells^{7,8} were transfected by the calcium phosphate precipitate technique^{7,9}. Cells treated with v-Ha-ras or v-myc DNA alone (see Fig. 1 legend) were repeatedly non-tumorigenic in nude mice, whereas cells co-transfected with v-Ha-ras and v-myc DNAs and injected 3 days later into nude mice formed tumours at 45-100% of the sites

Fig. 1 Histology of *v-Ha-ras* plus *v-myc*-induced tumour (2) diagnosed as pleomorphic sarcoma or fibrosarcoma with marked pleomorphism (a) and polyoma-induced tumour (4) diagnosed as a well-differentiated fibrosarcoma (b). Haematoxylin/eosin staining. ($\times 100$).

Methods. Tertiary cultures were established from 13-day-old Syrian hamster embryos as described previously⁸. Pools of primary cultures derived from littermates were cryopreserved in liquid nitrogen and secondary cultures were initiated from the frozen stocks. All experiments were performed with tertiary cultures. Plasmids [H-1 (ref. 26), pSVmyc⁵ (ref. 5) and PY1 (ref. 10)] containing genomic clones of Harvey murine sarcoma virus (*v-Ha-ras*), MC-29 viral DNA (*v-myc*) or polyoma virus DNA, respectively, were added to recipient cells by the calcium phosphate precipitate technique^{7,9}. Cells (3×10^5 per dish) were plated into 10 dishes overnight and then transfected as described with 1 μ g plasmid DNA per dish and 5 μ g of carrier calf thymus DNA. Three days after treatment, cells from each group were pooled and injected into nude mice or syngeneic newborn (3-day-old) Syrian hamsters at a dose of $4-6 \times 10^6$ cells per site and monitored for the appearance of subcutaneous tumours. No tumour formed in animals inoculated with cells treated with calf thymus DNA alone⁷. In contrast, cells treated with *v-Ha-ras/v-myc* or polyoma DNA formed tumours generally after short latency period (3-7 weeks). Tumours which formed were removed and fixed and histological sections prepared. Tumours also were minced into small (1 mm³) fragments, digested with 0.1% trypsin for 15 min, and re-established in culture.

injected, generally with a latency of 3-5 weeks⁷. These tumours, which were diagnosed as pleomorphic sarcomas or fibrosarcomas (Fig. 1a), grew progressively, reaching more than 3 cm in diameter in 2-3 weeks after detection, and were transplantable in nude mice. Cytoplasmic RNA dot-blot analysis indicated that the cells derived from the tumours expressed both *v-Ha-ras* and *v-myc* oncogenes (Fig. 2). Syrian hamster embryo cells treated with the plasmid PY1 containing the three polyoma genes¹⁰ (large-T, middle-T and small-T) were also tumorigenic, forming tumours at 21 of 22 sites injected⁷. The tumours from polyoma-treated cells had essentially the same latency period (4-7 weeks) in nude mice as the *v-Ha-ras* plus *v-myc*-induced tumours, but grew at a slightly slower rate, requiring 4-6 weeks to reach 2-3 cm in diameter; these tumours were diagnosed as well-differentiated fibrosarcomas (Fig. 1b). Tumour-derived cells expressed polyoma sequences (Fig. 2) and were readily transplantable into nude mice. Both polyoma-treated and *v-Ha-ras* plus *v-myc*-treated Syrian hamster embryo cells also formed tumours when injected into syngeneic newborn hamsters.

Q-banded karyotypic analyses^{11,12} of cells derived from six *v-Ha-ras* plus *v-myc*-induced tumours and five polyoma-induced tumours were performed at the first passage (Table 1). The modal karyotypes of all five polyoma-induced tumours (four isolated from nude mice and one from a newborn hamster) were normal diploid (Table 1, Fig. 3a), although 27-40% of the metaphase spreads had abnormal karyotypes, consisting of structural or numerical changes in four out of five of the tumours. However, no consistent change was observed in metaphases from the same tumour and no common changes were observed among tumours. Defendi and Lehman have reported that tumour-derived Syrian hamster cells transformed by polyoma virus apparently remain diploid¹³, but that random chromosome changes in these cells occur with time. Others have reported nonrandom chromosome changes in polyoma virus-transformed Syrian hamster cells several months after infection¹⁴.

Although all the karyotypes of the parental Syrian hamster embryo cells examined were normal, diploid (Table 1), a mixture of XX (61%) and XY (39%) cells were present as the cultures were established from pools of cells obtained from littermates of both sexes. Therefore, sex chromosomes and marker chromosomes were used as markers to determine whether the tumours were monoclonal or polyclonal in nature. Three of five of the polyoma induced tumours had cells with both XX and XY karyotypes (Table 1), indicating that the tumours were polyclonal in origin.

Fig. 2 RNA dot-blot analysis of polyoma and *v-Ha-ras* plus *v-myc* tumour-derived cell lines. Cytoplasmic extracts prepared from polyoma-1 (lane 1) and polyoma-2 (lane 2) tumour-derived cells were dotted onto a nitrocellulose filter and hybridized with ³²P-labelled polyoma DNA insert from clone PY1 (ref. 10). Cytoplasmic extracts prepared from Syrian hamster embryo cells (lanes 3, 6), *ras/myc*-1 (lanes 4, 7) and *ras/myc*-2 tumour cells (lanes 5, 8) were dotted onto nitrocellulose filters and hybridized with either the ³²P-labelled *v-Ha-ras* insert from clone BS9 (ref. 27) (lanes 3-5) or the ³²P-labelled *v-myc* insert from clone pBRmyc²⁸ (lanes 6-8).

Methods. Extracts from 2×10^6 tumour-derived cells or normal cells prepared by the method of White and Bancroft²⁹, and four aliquots representing $0.25-2.0 \times 10^5$ cell equivalents were applied to a nitrocellulose sheet using a Hybri-Dot Manifold (BRL). The filters were heated at 80 °C *in vacuo* for 2 h and hybridized to DNA which had been ³²P-labelled by nick-translation ($1-2 \times 10^8$ c.p.m. μ g⁻¹). Hybridizations were performed in 1 $\times$ Denhardt's solution (0.2% each of bovine serum albumin, Ficoll and polyvinylpyrrolidone), 5 $\times$ SSC (1 $\times$ SSC is 0.15 M sodium chloride, 0.015 M sodium citrate), 50% formamide, 50 mM potassium phosphate (pH 6.5), 0.25% SDS, 200 μ g ml⁻¹ salmon sperm DNA, and 10^6 c.p.m. ml⁻¹ for 48 h at 42 °C. Filters were washed in $0.1 \times$ SSC, 0.1% SDS at 50 °C and autoradiographed.

In contrast to the polyoma-induced tumour cells, the cells from the *v-Ha-ras* plus *v-myc*-induced tumours were karyotypically abnormal (Table 1). All of the cells from the *ras/myc*-1 tumour were of XX origin and had two common chromosomal abnormalities in all of the metaphase spreads: monosomy 15 and a translocation (X') between an X chromosome (at the breakpoint Xpa7) and an unidentified chromosome. However, detailed banding analysis revealed that this unidentified chromosome segment is quite distinct from chromosome 15. Half of the cells had two X' chromosomes (the modal karyotype of the tumour cells was 44, XX'X', -15) (Fig. 3b). These results suggest that the *ras/myc*-1 tumour is monoclonal and X' and -15 are early karyotypic changes. The vast majority of *ras/myc*-2 tumour

Table 1 Cytogenetic findings in Syrian hamster tumours induced by v-Ha-ras plus v-myc or polyoma oncogenes

<i>ras/myc-3‡</i>		21	42	None of the cells had the same karyotype	-10,-11,-15	0:0:50	No cells with normal karyotype
<i>ras/myc-4†</i>		4	45	46,Y,+1,+14,-15,+19,t(Xq;9p), 6q+	-15,t(Xq;9p)	0:0:50	Two cells were 44,XY; tumour formed in newborn male hamster§
<i>ras/myc-5‡</i>		7	43	43,X,+3,-15	-X or -Y, +3,-15	0:50:0	90% of the cells had double minute chromosomes. No cells with normal karyotype
<i>ras/myc-6‡</i>		4	43	43,XY,-15	-15	0:0:50	No cells with a normal karyotype

Tumours were induced following transfection with the indicated plasmids, as described in Fig. 1 legend. Tumour-derived cell lines were established in IBR-modified Dulbecco's Eagle's reinforced medium (Gibco) supplemented with 3.7 g l⁻¹ sodium bicarbonate, 20% (v/v) HyClone fetal bovine serum (Sterile Inc., Logan, Utah), 100 U ml⁻¹ penicillin and 100 µg ml⁻¹ streptomycin (Gibco). Chromosome slides were prepared by the method described previously³⁰ from the tumour-derived cell cultures at first passage. For chromosome counts, the Giemsa-stained slides were used. For banding analyses, 50 Q-banded metaphase spreads were photographed and analysed. Common chromosome changes are abnormalities observed in all the cells with an abnormal karyotype.

* In *ras/myc-1*, half of the cells (25/50) contained XX' sex chromosomes; the X' was duplicated in the remaining 25 cells, that is, XX'X'. Thus, all 50 cells were considered to be of XX origin. In *ras/myc-2*, the 11 cells with an indicated XX constitution included 10 with XX and 1 with XXX. In *ras/myc-4*, all of the 50 cells contained a Y chromosome and 48 of 50 cells had an abnormal X chromosome, that is, del(Xq); the deleted segment was probably translocated to the short arm of chromosome 9. Thus, all the cells were considered to be of XY origin.

† Tumours formed in syngeneic newborn Syrian hamsters.

‡ Karyotypic analyses of cells obtained directly from the tumours and/or from tumour-derived cell cultures at first passage. Both methods showed similar karyotypic results; the data from the direct preparation are shown.

§ A small percentage (4%) of the *ras/myc-2* and *ras/myc-4* tumours showed a normal diploid karyotype (44,XY); these cells may have been of host origin (in the case of *ras/myc-4*) or may represent a rare subpopulation of normal diploid tumour cells, or non-tumour cells that exist in the tumour.

cells had also lost a chromosome 15; out of 50 cells examined, monosomy of chromosome 15 was the sole karyotypic change in 11 cells and 37 cells were monosomic for both the X chromosome and chromosome 15. Two of the cells had a normal karyotype (44,XY) (Table 1). Because 96% of the cells were monosomic for chromosome 15 and in some cases this was the sole karyotypic change, loss of chromosome 15 was probably the first karyotypic change in the transformed cells, with loss of the X chromosome an additional change, which occurred later.

The *ras/myc-3* tumour had a longer latency period than the other tumours and the karyotypes of the cells were more diverse than those of the other tumour-derived lines. No modal karyotype was evident; however, all cells displayed karyotypic alterations and losses of chromosomes 10, 11 and 15 were common changes in all of the metaphase spreads examined (Table 1). The *ras/myc-3* tumour was also examined after a culture period

of only 2 hours to obtain mitotic cells directly from the tumour; the karyotypes of these cells had the same common abnormalities as the cells at first passage. Cells from the *ras/myc-4* tumour, which formed in a male, newborn hamster, were monosomic for chromosome 15 and had a translocation between the X chromosome and chromosome 9, that is, t(X;9) (qa5-7; pa4) (Table 1). Two of the 50 cells examined were normal 44,XY but these may have originated from the male host. All the cells from the *ras/myc-5* tumour showed the absence of an X or Y chromosome and monosomy 15, together with an additional chromosome 3. No karyotypically normal cells were observed. This tumour was also examined when it was still relatively small (~5 mm in diameter) and all the cells analysed directly from the tumour showed monosomy of chromosome 15. All *ras/myc-6* tumour cells had lost a chromosome 15 and no cells with a normal karyotype were observed.

The results presented here indicate that, in contrast to the

Fig. 3 *a*, Q-banded normal, diploid karyotype of a polyoma-induced tumour (2) at first passage. *b*, Q-banded karyotype of a cell with 44,XX,X⁻15 karyotype in *ras/myc*-1 tumour at first passage. The two arrows indicate two X⁻ chromosomes, and the arrowhead indicates a missing chromosome 15. The translocation (X¹) was between the X chromosome (at the breakpoint Xpa7) and an unidentified chromosome. In this cell, two X¹ chromosomes are seen. Chromosome slides were prepared by the method described previously³⁰. The cells were banded with the quinacrine fluorescence dye for karyotypic analysis¹¹. The nomenclature of Syrian hamster chromosomes proposed by Li *et al.*¹² was used.

findings with the polyoma-induced tumours, the v-Ha-*ras* plus v-*myc*-induced tumours were karyotypically abnormal and the cells from all six tumours had a nonrandom chromosome change, that is, monosomy of chromosome 15. Furthermore, the presence of a single sex chromosome and marker chromosomes in the v-Ha-*ras* plus v-*myc*-induced tumours indicates that most of the cells in the tumours are monoclonal in nature. The monoclonality of the tumours may result from a low efficiency of transfection. However, the cells used in the experiments efficiently express pSV2neo DNA following transfection⁷ and the majority of the polyoma-induced tumours were polyclonal. These findings, although not conclusive, suggest that an additional, rare change is needed for these tumours to develop. As we have identified the nonrandom loss of chromosome 15 as the possible additional change, the monoclonal nature of the *ras/myc* tumours is consistent with this hypothesis.

We cannot determine whether the loss of one chromosome 15 is an early event necessary for the genesis of tumours induced by v-Ha-*ras* plus v-*myc* or whether this change represents a cellular progression that occurs with a high frequency and is strongly selected. The latency periods of the tumours were unrelated to the nonrandom chromosome change, but the diploid polyoma-induced tumours grew more slowly and were more differentiated in appearance than the aneuploid *ras/myc* tumours. However, the fact that the polyoma-induced tumours did not show monosomy of chromosome 15 must indicate either that this change does not result in a selective advantage for the polyoma-transformed cells or that transfection with v-Ha-*ras* and v-*myc* DNAs induces this change more frequently than treatment with polyoma DNA. It is interesting to consider whether the loss of chromosome 15 is associated with any particular stage such as immortalization¹⁵ or tumorigenicity in the neoplastic progression of the Syrian hamster embryo cells. Karyotypic analyses of carcinogen-induced and spontaneously immortalized Syrian hamster embryo have not revealed any association with monosomy 15; in fact, a nonrandom gain of another chromosome (11) was observed¹⁶. However, transfection of immortalized cell lines with v-Ha-*ras* alone results in tumorigenic transformation⁷ and with some cell lines, a nonrandom loss of chromosome 15 was observed (unpublished data). Thus, the existing data indicate that the loss of chromosome 15 is closely associated with a later stage in the neoplastic progression of these cells.

Nonrandom chromosome loss has been observed in a variety of human and animal tumours and transformed cells^{1,2,17-19}. Pathak *et al.*²⁰ observed that 15 of 18 virus (simian adenovirus-7, chicken embryo lethal-orphan, herpes simplex and simian papova viruses)-transformed Syrian hamster cell lines were monosomic for chromosome 15. This result is similar to our findings with *ras/myc*-induced tumours.

We interpret our results to indicate that the loss of a specific chromosome results either in the loss of a cellular gene which effects a phenotypic change necessary or advantageous for neoplastic development or in the deletion of *trans*-acting cellular

sequences³ which regulate the expression of either the v-Ha-*ras* or v-*myc* genes. This additional change either occurred spontaneously in these cells or may have been induced by transfection with v-Ha-*ras* plus v-*myc* DNAs. Several authors have also proposed that the dosage of cellular factors regulates the expression of tumorigenicity in viral and chemically transformed cells²¹⁻²³. Chromosome loss from hybrids between normal and malignant cells^{24,25} results in the expression of tumorigenicity. In contrast to cell hybridization studies which suggest that tumorigenicity is a recessive phenotype^{24,25}, DNA transfection studies have indicated that tumorigenesis is due to dominantly acting genetic elements²⁶. Our findings that chromosome loss can occur after DNA transfection and tumour formation may help to resolve these seemingly disparate conclusions. The oncogene-transfection system may be useful for understanding chromosomal control in carcinogenesis and the role of cellular factors in the regulation of the expression of oncogenes and tumorigenicity.

We thank Erika Matkin, Pattie Lamb and Lois Annab for technical assistance and Alma Gonzalez for typing the manuscript. We also thank Drs Ester Chang for Harvey murine sarcoma virus clones H-1 and BS9, Robert Weinberg for clone pSVvmyc and Robert Kamen for clone PY1.

EGF receptor-associated DNA-nicking activity is due to a M_r -100,000 dissociable protein

Mitali Basu*, Kevin Frick†, Anis Sen-Majumdar*, Charles D. Scher† & Manjusri Das*

The receptor for epidermal growth factor (EGF) is a single-chain transmembrane polypeptide of relative molecular mass (M_r) 170,000 (170K) which has been implicated in the regulation of both normal and abnormal cell proliferation¹. It has an externally facing EGF-binding domain and a cytoplasmically facing tyrosine-specific protein kinase site. Although the receptor has been well characterized²⁻⁴, the mechanism by which it transmits the growth stimulatory signal from the plasma membrane to the nucleus is unclear. EGF binding to cells has been shown to enhance topoisomerase activity within the cells⁵. Topoisomerases catalyse the interconversion of topological isomers of DNA and thus may influence replication and transcription⁶. Mroczkowski *et al.*⁷ reported that purified EGF receptors of both human and murine origin can nick supercoiled double-stranded (ds) DNA in an ATP-dependent fashion, an activity related to those of topoisomerases⁶. Another related tyrosine kinase, pp60^{src}, has also been reported to have a similar DNA-nicking activity⁷. We have now characterized the EGF receptor-associated DNA-nicking activity by sucrose gradient centrifugation. Our results, presented here, indicate that the DNA-nicking activity is not intrinsic to the EGF receptor, but is found in a distinct molecular species.

The EGF receptor was solubilized and purified from plasma membranes of human A431 epidermoid carcinoma cells⁷⁻¹⁰. Receptor at various stages of purification (involving chromatography on EGF-AffiGel, wheat-germ lectin(WGA)-Sephacrose, and DNA-agarose) was tested for its ability to convert pBR322 DNA from form I to form II. Figure 1 shows the results obtained with equivalent amounts of receptor (measured by EGF-binding activity) at different stages of purification. As found previously, the DNA-nicking activity was ATP-dependent (Fig. 1a) and sensitive to KCl (Fig. 1b) and NaCl (not shown).

Form I DNA was converted to form II with no evidence of intermediate topoisomers, suggesting that the observed activity is an ATP-dependent nicking of supercoils rather than a classical topoisomerase activity. Further purification of the receptor on WGA-Sephacrose revealed that while over 80% of the EGF-binding activity was adsorbed to the column, most of the DNA-nicking activity was recovered in the unadsorbed fraction (not shown). The material eluted from the WGA-Sephacrose had markedly less DNA-nicking activity (per EGF-binding unit) than did the preparation loaded onto the column (Fig. 1). Nevertheless, the remaining DNA-nicking activity was still ATP-dependent and KCl-sensitive (Fig. 1b). These results demonstrate that the DNA-nicking activity found in the EGF-AffiGel-purified receptor preparation does not co-purify with the EGF receptor through the WGA-Sephacrose step.

To confirm that EGF-binding and DNA-nicking activities are distinct, EGF-AffiGel-purified receptor was sedimented on a 5–20% sucrose gradient. Most (~80%) of both the EGF-binding activity and tyrosine autokinase activity co-sedimented at 7.7S (Fig. 2), with a minor peak of EGF-binding activity at 12S as a result of receptor dimerization, in agreement with our previous findings¹⁰. No DNA-nicking activity was seen at either 7.7S or 12S; a single peak of ATP-dependent DNA-nicking activity was seen at ~5.5S (M_r ~100,000), clearly separated from the EGF-binding and tyrosine kinase activities. Receptor further purified through WGA-Sephacrose and DNA-agarose gave identical results (not shown).

The results described above suggest that DNA-nicking activity is not an intrinsic activity of the 170K EGF receptor polypeptide. It is possible, however, that the DNA-nicking activity is the novel activity of a proteolytic cleavage product of the receptor. Trypsin treatment might thus be expected to enhance the DNA-nicking activity of receptor preparations; however no such increase was found (data not shown). Thus, evidence now available points to the conclusion that the observed DNA-nicking activity is due to an associated enzyme not related to the EGF receptor.

Note that the ratio of DNA-nicking protein to EGF-receptor protein is extremely small in our purified preparations. This is evident in the lack of detectable 100K protein (or proteins of lower M_r) in silver-stained gels (data not shown), and also in the microgram quantities of receptor protein needed for detection of DNA-nicking activity (Fig. 1).

Is the association between tyrosine kinases and ATP-dependent DNA-nicking proteins purely fortuitous? Topoisomerases are known to be bound to the 5' end of the nicked DNA through

Fig. 1 Separation of DNA-nicking activity and EGF-binding activity during WGA-Sephacrose chromatography. Supercoiled pBR322 DNA (0.2 µg) was incubated with an equivalent amount (0.5 pmol) of EGF receptor at the indicated stages of purification (amount of receptor was deduced by Scatchard analysis of ¹²⁵I-EGF-binding data). *a*, DNA-nicking activity in the presence and absence of receptor and ATP. *b*, Receptor-mediated DNA-nicking activity in the presence and absence of ATP and KCl. EGF-Affi., EGF-AffiGel; WGA-Seph., WGA-Sephacrose; DNA-agar., DNA-agarose.

Methods. Agarose gel electrophoresis was performed on 0.8% agarose gels in 40 mM Tris-acetate pH 7.9, 20 mM sodium acetate at room temperature for 18 h at 100 mA. The gels were stained with ethidium bromide (1 µg ml⁻¹), de-stained in water, and photographed under ultraviolet illumination. EGF receptor was solubilized from A431 plasma membranes and subjected to EGF-AffiGel chromatography^{3,8,9}. The EGF-AffiGel-purified receptor was subjected to further purification WGA-Sephacrose (Vector Laboratories) and ds DNA-agarose (Sigma)⁷. EGF-binding activity of the receptor preparation was determined as described elsewhere⁹. The amount of receptor present was deduced by Scatchard analysis of the ¹²⁵I-EGF-binding data, assuming a 1:1 complex of EGF and receptor. The conversion of supercoiled (form I DNA) to nicked DNA (form II DNA) was carried out as described⁷ in 20 µl of 20 mM HEPES pH 7.4, 5% glycerol, 0.1% Triton X-100, 5 mM MgCl₂ containing 0.5 pmol of receptor (or no receptor), 5 mM ATP (or not ATP), 0.15 M KCl (or no KCl). After a 30-min incubation at 20 °C the reaction was stopped by adding 5 µl of 10% SDS. Alternatively, the DNA was precipitated by adding 3 µl of 3 M sodium acetate, and 70 µl of absolute ethanol at -20 °C. The products were analysed by agarose gel electrophoresis.

Fig. 2 Separation of the DNA-nicking activity and EGF-binding activity by sedimentation analysis. Sedimentation rates and M_s were estimated as described elsewhere^{10,14}. Approximately 10 pmol of EGF-Affigel-purified receptor (in 100 μ l of 20 mM HEPES pH 7.4, 0.2% Triton X-100 and 3% glycerol) was centrifuged at 4°C for 9.5 h at 45,000 r.p.m. in a SW 50.1 swinging bucket rotor, through a 5–20% sucrose gradient (5 ml) in 20 mM HEPES pH 7.4, 0.2% Triton X-100 (ref. 10). The standard proteins (applied to separate tubes) were: bovine serum albumin (4.6S), human IgG (7S), and horse catalase (11S). At the end of the run, the tubes were punctured at the bottom and fractions were collected. Assays for standard proteins, EGF binding and autophosphorylation have been described elsewhere¹⁰. The EGF-binding values plotted (●) are specific binding data with 150 nM ¹²⁵I-EGF (150,000 c.p.m. ng⁻¹) which were obtained after subtraction of nonspecifically bound radioactivity (~4,000 c.p.m.). Receptor autophosphorylation (Δ) was quantified, after SDS-polyacrylamide gel electrophoresis⁸ of the gradient fractions reacted with 5 μ M [γ -³²P]ATP (100 c.p.m. fmol⁻¹), by counting gel slices containing the 150K/170K receptor band¹⁰. For assay of DNA-nicking activity, 100 μ l of each fraction was incubated with 10 μ l of a solution containing 50 mM MgCl₂, 40 mM ATP and 0.2 μ g of supercoiled pBR322 DNA. After incubation at 20°C for 30 min, the DNA was precipitated by adding 12 μ l of 3 M sodium acetate and 360 μ l of absolute ethanol at -20°C. The precipitate was subjected to agarose gel electrophoresis as described in Fig. 1 legend.

a phosphotyrosine linkage^{11,12}. The phosphorylation of this critical tyrosine by pp60^{src} (like the EGF receptor, a tyrosine-specific protein kinase) causes a drastic loss of topoisomerase activity¹³. Thus, it is probable that topoisomerase-related proteins associate with tyrosine kinases such as EGF receptor in an enzyme-substrate sense.

Mitochondrial class II introns encode proteins related to the reverse transcriptases of retroviruses

François Michel* & B. Franz Lang†‡

* Centre de Génétique Moléculaire du CNRS, Laboratoire propre associé à l'Université Pierre et Marie Curie, 91190 Gif-sur-Yvette, France

† Institut für Genetik und Mikrobiologie der Universität München, Maria-Ward-Straße 1a, D 8000 München 19, FRG

Organelle introns share several distinctive features that set them apart from their counterparts in nuclear-encoded pre-messenger RNAs (reviewed in ref. 1): (1) their termini do not obey the GU...AG rule; (2) the introns are 'structured' (members of the same family or 'class' can theoretically adopt very similar RNA secondary conformations^{1–3} and several of the postulated pairings have been confirmed by studies of splicing mutants and their revertants (see, for example, ref. 4); (3) many introns from both classes contain long open reading frames^{4–10}. We report here that the proteins potentially encoded by four class II introns are related to several RNA-dependent polymerases of viral and transposable element origins.

Four mitochondrial members of class II contain long open reading frames: introns a1 and a2 in the cytochrome oxidase subunit I gene of the yeast *Saccharomyces cerevisiae*⁵; an intron in the corresponding gene of the filamentous fungus *Podospora anserina*¹¹; and the single intron in the apocytochrome *b* gene of *Schizosaccharomyces pombe*¹². The sequences of these introns are sufficiently similar to be aligned over most of their length. Recently, the protein potentially encoded by a mitochondrial plasmid of the Mauriceville-1c strain of *Neurospora crassa*¹³, another filamentous fungus, was shown to constitute the fifth known member of this family¹². The relationship is rather distant, as alignment of the plasmid-encoded protein with the four intronic ones is only possible over short amino-acid stretches (blocks I–VII in Fig. 1), all located in a section that does not span more than one-third of the estimated length of the molecules.

The possibility of the Mauriceville plasmid being related to transposable elements was suggested by Nargang *et al.*¹³. To test this hypothesis, we compared the seven amino-acid stretches conserved in the plasmid putative protein product and its intronic relatives with those characteristic of a family of RNA-dependent polymerases, which includes the products of the *pol* genes of retroviruses and a *copia*-like element as well as the related proteins encoded by cauliflower mosaic and hepatitis B viruses^{14–16} (segments III, IV and V in Fig. 1 correspond to segments I, II and III, respectively, of ref. 15).

As shown in Fig. 1, each of the mitochondrial conserved segments has a counterpart in viral sequences. Moreover, not only is the order of conserved blocks the same in the two sets, but distances (in amino acids) from one block to the next are rather similar, with two exceptions: the four intronic proteins (but not that encoded by the Mauriceville plasmid) have large insertions of poorly conserved sequence between segments IV and V; the Mauriceville plasmid sequence (and also that of the hepatitis B viral protein) possesses a large insertion between segments III and IV. Note also that 9 of the 10 residues found by Toh *et al.*¹⁴ to be invariant in the set of RNA-dependent polymerases they compared could each be identified in at least 4 of the 5 mitochondrial sequences.

The section of the *pol* gene that has a counterpart in the reading frames of class II introns is thought to be responsible for the polymerase activity (see ref. 14). Two lines of evidence have already indicated the presence of a reverse transcription

‡ Present address: Institut de Biologie Moléculaire et Cellulaire du CNRS, 15 rue Descartes, 67084 Strasbourg, France.

Fig. 1 Alignment of similar segments in mitochondrial intron- and plasmid-encoded proteins and RNA-dependent polymerases. Amino-acid sequences were deduced from nucleotide sequences. Mitochondrial sequences are those of the proteins potentially encoded by introns S.c.a1 and S.c.a2 of *S. cerevisiae*⁵, P.a.a1 of *P. anserina*¹¹ and S.p.b1 from *S. pombe*¹², together with that of the putative protein product of a *N. crassa* plasmid¹³ (N.c.mau.). Retroviral sequences are those of the *pol* genes of Rous sarcoma virus³² (RSV), human adult T-cell leukaemia types I and II viruses^{33,34} (HTLV-I and -III) and Moloney murine leukaemia virus (MoMLV)³⁵. Other sequences are those of the putative polymerase of cauliflower mosaic virus³⁶ (CaMV), the product of the *pol*-like gene 17.6 (ref. 16), a transposable element and a putative polymerase encoded by hepatitis B virus³⁷ (HBV). Amino acids that are conserved in at least four sequences belonging to two different sets are boxed (only the most common amino acid at any single site is boxed). Note that many substitutions, even at the less-conserved sites, are conservative. Arrowheads point to the location of 9 of the 10 amino acids reported as invariant by Toh *et al.*¹⁴.

activity in fungal mitochondria. First, a number of *S. cerevisiae* intronic mutants revert preferentially by clean excision of the affected intron and often of one or more of its immediate neighbours¹⁷ (genetic arguments even suggested that intron-encoded proteins are involved in the process). Second, the most common form of senescence in *P. anserina* is associated with proliferation of a mitochondrial plasmid whose sequence coincides precisely with that of an intron in the cytochrome oxidase subunit I gene of this fungus¹¹. This intron is one of the four class II members discussed here.

On the other hand, the phenotypes associated with mutations in the reading frame of intron a1 of *S. cerevisiae* point to an activity other than reverse transcription. The reading frame of intron a1 continues that of the upstream exon⁵. This is the most commonly encountered situation in organelle introns and has

led to the view that their primary translation products are chimaeric proteins^{7,18,19}, another point of convergence with retroviruses and transposable elements²⁰⁻²². But although the level of expression of *pol* gene products seems to be adjusted at the translation stage (see, for example, ref. 22), synthesis of intron-encoded proteins has been postulated to be regulated at the post-transcriptional level. This is termed the 'maturase'^{7,18} or 'splicing'¹⁹ model, according to which chimaeric protein translated from a pre-mRNA molecule (or its proteolytic derivatives, see Fig. 2) contributes to the destruction of its own mRNA by participating in the splicing process (in this model it is assumed that the excised form of the intron, which, in the case of a1, is a stable circular RNA²³, does not give rise to a functional translation product). Several *trans*-recessive splicing-deficient mutations have been identified that map within the open reading frame of intron a1 and block its excision²⁴.

However, that the protein encoded by intron a1 should be involved in excision of the intron does not contradict the fact that part of it is related to reverse transcriptases. Several structured introns catalyse their own excision from primary transcripts without the need for a protein helper^{25,26} (the best-known example is provided by the *Tetrahymena* ribosomal intron, one of the few nucleus encoded class I introns^{1,27,28}). Thus, as far as splicing is concerned, maturases seem to be accessory devices and maturase activity could have evolved from intron-associated proteins as a form of self-regulation. On the other hand, possession of a specialized reverse transcriptase, although of no normal use in organelles, could be of decisive advantage in the maintenance and propagation of structured introns in the genomes of organelles. Thus, it will be of interest to determine whether the proteins encoded by class II introns have a DNA endonuclease activity similar to that believed to be involved in integration of retroviral DNA into the host genome²⁹⁻³¹, which is encoded by the 3' section of *pol* genes (see Fig. 2).

We thank B. Dujon and P. Slonimski for discussions.

Fig. 2 Organization and expression of the *pol* gene of avian sarcoma-leukosis virus (ALV) compared with those of intron a1 in the cytochrome oxidase subunit I gene of *S. cerevisiae*. *a*, The gene and its products, redrawn from ref. 38; *b*, intron a1, redrawn from ref. 24. Homologous sections in the two genes (see Fig. 1) are hatched. Primary translation products are sketched as thick lines with an arrow-shaped extremity that indicates the direction of translation. Vertical arrows point to proven or presumed sites of proteolytic cleavage; st, sections of intron a1 that participate in class II secondary structure ('core' of the intron, see ref. 2). In the case of intron a1, the active product has been proposed to be p68 (ref. 24), a polypeptide which seems to correspond to most or all of that part of the intronic reading frame that is looped out of the structured core of the intron by long-range potential base pairings, also well conserved in evolution^{2,12}.

Haemophilia B caused by a point mutation in a donor splice junction of the human factor IX gene

D. J. G. Rees, C. R. Rizza* & G. G. Brownlee

Sir William Dunn School of Pathology, University of Oxford, South Parks Road, Oxford OX1 3RE, UK

*Haemophilia Centre, Churchill Hospital, Oxford OX3 7LJ, UK

Haemophilia B (Christmas disease) is an inherited, recessive, sex-linked, haemorrhagic condition caused by a defect in the intrinsic clotting factor IX. This disease occurs in males at a frequency of ~1 in 30,000. Patients differ in the severity of their clinical symptoms, and variation in the clotting activity and in the concentration of factor IX antigen in their plasma has been demonstrated¹. There is probably heterogeneity in the molecular defects of the factor IX gene causing the disease. Here we study a severely affected, antigen-negative patient, and show that the only significant sequence difference from the normal factor IX gene is a point mutation changing the obligatory GT to a TT within the donor splice junction of exon f. We infer that this change is the cause of the disease in this individual. In addition, we have used oligodeoxynucleotide probes specific for this mutation to demonstrate the feasibility of carrier detection and prenatal diagnosis for relatives of the patient.

The characterization of the normal factor IX gene² made it possible to characterize haemophilia B at a genetic level. Approximately 40% of patients have a normal concentration of factor IX antigen (IXAg) in their plasma³ and probably have point mutations in the coding sequence giving rise to single

amino-acid changes such as that found in factor IX^{Chapel Hill} (ref. 4). A few patients (1%) produce antibodies to the injected factor IX used in replacement therapy and here the defect appears, in most cases, to be large deletions in the factor IX gene⁵. The remaining 60% of patients have either markedly reduced or undetectable levels of IXAg and can be described as cross-reactive-material negative (CRM negative)¹. It is plausible that the defect in this group of patients could be either mutations resulting in a reduction in the amount of factor IX messenger RNA, or chain termination mutations causing the production of truncated and presumably unstable factor IX protein.

The patient (D.B.) chosen to test this hypothesis falls into the severe, CRM-negative class, having 0.3% factor IXAg⁶ (assayed by radioimmunoassay⁷) and <0.5% factor IX clotting activity⁶ (assayed by two-stage thromboplastin generation assay⁸). A genomic cosmid library was prepared from DNA isolated from the patient's peripheral blood lymphocytes and cloned in the cosmid vector pTM (ref. 9). Four recombinant clones containing factor IX sequences were isolated and mapped as before² (Fig. 1). From these clones, all eight exon regions were separately subcloned and sequenced¹³, except for that part of exon h corresponding to the 3' noncoding section of the mRNA. The sequences determined totalled 5,200 bases, covering the presumptive promoter, the 5' noncoding region of the mRNA, all protein-coding sequences and the polyadenylation signal AATAAA.

The sequence was found to be identical to the previously published normal factor IX gene² with 14 exceptions. A G→T change was found at position 21,165, within the obligatory GT of the donor splice site at the 3' site of exon f (Fig. 2), which changes an *RsaI* site in the normal sequence to a *MaeIII* site

Fig. 1 Line diagram of the positions of clones isolated from patient D.B. in relation to the organization of the factor IX gene. *a*, The position of the eight exons *a-h*; *b*, the position of cosmid clones isolated from patient D.B.; *c*, the subclones generated for sequencing.

Methods. DNA was isolated¹⁰ from peripheral blood lymphocytes from 100 ml of whole blood. It was partially restricted with *MboI* and size fractionated on a 1-5 M NaCl gradient⁹. DNA in the size range 35-45 kb was pooled, ligated into the cosmid vector pTM⁹, packaged into bacteriophage λ heads¹⁰ and allowed to infect *Escherichia coli* ED 8767 (ref. 11). 1.5×10^6 clones were screened by colony hybridization¹² using previously isolated factor IX probes XI,

IV and cVII (ref. 2). Positive clones were mapped by digestion with restriction enzymes to the positions shown by comparison with maps of previously characterized genomic clones. Clone pDB3 contains approximately 15 kb of the factor IX gene ligated to approximately 20 kb from elsewhere in the genome as a result of a cloning artefact. Subclones constructed for sequencing were derived by restriction digestion of the appropriate cosmid clone and isolation of the required fragments, which were "filled in" with deoxynucleoside triphosphates using the Klenow fragment of *E. coli* DNA polymerase I¹⁰ and blunt-end ligated into the vector pATX (C. Naeve, unpublished) except for subclones XIV and VI. These were ligated directly into the *EcoRI* site of pBR322. The restriction sites at the ends of each subclone are: B, *BglII*; E, *EcoRI*; H, *HindIII*; L, *BglII*; P, *PvuII*. Subclones are numbered as before².

Fig. 2 The sequence surrounding the 3' end of exon f of the normal factor IX gene showing the position of the G→T mutation found in the donor splice site in patient D.B. The other sequence changes found in D.B. were G→C at position 6,928 at a previously discovered polymorphic *Xmn*I site¹⁴, T→C at position 34,037 and A→G at an unmapped position not more than 1.4 kb from the 3' end of the gene. Nine other differences reflected sequence errors in the normal factor IX gene sequence and corrections to Fig. 4 of ref. 2 are as follows: 138 = G, 139 = A, 309 = T, 310 = C, 319 = A, delete residues 6,050, 34,026 to 34,031 and 34,093, insert T between residues 34,107 and 34,108 and insert T between residues 34,170 and 34,171. (Fig. 2 of ref. 2 should also be corrected at the three relevant positions.)

in the patient. A G→C change was found at position 6,928 resulting in the loss of an *Xmn*I site previously shown to be polymorphic in normal populations¹⁴ (see Fig. 2 legend). Two further differences were found 3' to the factor IX gene (see Fig. 2 legend), and these may also be polymorphic but do not result in the change of any restriction enzyme sites. The 10 remaining differences were all caused by errors in the normal factor IX sequence² (see Fig. 2 legend).

To test the feasibility of directly assaying the molecular defect in total DNA isolated from peripheral blood lymphocytes, we synthesized oligodeoxynucleotide probes¹⁵, designed according to the principles developed to detect point mutations in globin genes¹⁶, to analyse this mutation in the patient and his mother (Fig. 3). Two 19-base long oligodeoxynucleotides (probes 1 and 2; see Fig. 3 legend) were used to hybridize to uncloned and cloned sequences under conditions in which only exactly matching sequences hybridized¹⁶. Probe 1 (exactly complementary to the normal factor IX sequence) hybridizes to a 1.1-kilobase (kb) *Pvu*II restriction fragment² in digests of DNA isolated from a normal male, from a normal female, from a cell line with 4X chromosomes (GM1416) and from the patient's mother (M.B.) (Fig. 3B a-c, e), as well as in *Pvu*II-restricted cloned normal factor IX DNA (Fig. 3B g). Thus, probe 1 hybridizes to the correctly sized restriction fragment and with the intensity expected

for an X chromosomal sequence (that is, with a ratio of intensities of about 1:2:4 on 1X, 2X and 4X genomic DNA). In addition, probe 1 fails to hybridize to the mutant sequence either in uncloned or cloned DNA (Fig. 3B d, f).

Probe 2 (exactly complementary to the mutated sequence in the patient) hybridizes to the same restriction fragment only in *Pvu*II digests of DNA isolated from the patient, his mother and the cloned mutant factor IX gene (Fig. 3B k-m) and fails to hybridize to the normal sequence (Fig. 3B h-j, n). Thus, these probes differentiate specifically between the normal and mutant sequences and in addition confirm that the base change characterized is not a cloning artefact. Both probes also hybridize to the DNA isolated from the patient's mother, in agreement with her obligatory carrier status (Fig. 3). If DNA were available from II₅ and II₆, it would be possible to determine their carrier status. If they are carriers, both probes 1 and 2 would hybridize whereas if not, only probe 1 would hybridize. It would also have been possible to use digestion with *Rsa*I and Southern blot analysis to assay the molecular defect directly. This should show a patient-specific fragment of 1.3 kilobases (kb) when probed with probe III², compared with a normal fragment of 1.1 kb.

We then analysed the DNA from nine other unrelated CRM negative patients whose factor IX antigen levels ranged from 1 to 6% of normal in a radioimmune assay^{6,7}. Under identical hybridization conditions to those used above, all hybridized to probe 1 (Fig. 4) and failed to hybridize to probe 2 (results not shown), indicating that they had the normal sequence at this position. Presumably the defect in these patients occurred elsewhere in the factor IX gene, either in other splice donor or acceptor sequences or other sequences essential for normal gene expression, as has been found to be the case in α and β thalassaemias¹⁷.

We have shown that a point mutation (G→T) within the obligatory GT of a donor splice junction is the only significant sequence change in the factor IX gene from patient D.B. It is well established that this dinucleotide is highly conserved¹⁸ and essential for the normal splicing of pre-mRNA to mRNA so that any alteration of this sequence would be expected to perturb this process. Perhaps the most convincing supporting evidence is that mutations in the GT of donor splice sequences in th

Fig. 3 **A**, family tree of the D.B. family showing the inheritance of haemophilia B. ■, Affected male; ○, obligatory carrier. The status of II₅ and II₆ is unknown. **B**, oligonucleotide hybridization studies. Two oligonucleotide probes were synthesized¹⁵, being complementary to residues 21,157-21,175. Probe 1 is the normal sequence 5' GTATAAAGTACCTGCCAAG 3' and probe 2 is the mutated sequence 5' GTATAAAGTAACTGCCAAG 3', differing from probe 1 at position 11. These were used for hybridization studies to genomic and cloned factor IX sequences as shown. a-e, h-l contain 15 µg of the indicated genomic DNA; f, m, 0.5 ng and 10 ng respectively of pDB8; g, n, 0.5 ng and 10 ng respectively of pGM3 (a cosmid clone, containing the 5' half of the normal factor IX gene, D.J.G.R., unpublished). DNA samples were digested to completion with *Pvu*II and electrophoresed in a 20-cm 0.7% agarose gel in 90 mM Tris, 90 mM boric acid, 2.5 mM EDTA, pH 8.3. The gel was then treated as described by Conner *et al.*¹⁶. 50 ng of each oligonucleotide was labelled with [γ -³²P]ATP using T4 polynucleotide kinase (Amersham) to a specific activity of 10⁹ d.p.m. µg⁻¹ and hybridized to the dried gel for 16 h at 42 °C. The gels were then washed as described, with a final temperature of 60 °C in 6 × SSC¹⁶.

Fig. 4 Hybridization of ^{32}P -labelled probe 1 to DNA (15 μg per track) from nine CRM-negative haemophilia B patients from unrelated kindreds⁶ (tracks 1-9). The samples were digested, electrophoresed in 0.7% agarose, hybridized and washed as described in Fig. 3. 1X and 4X DNA samples (15 μg) were included as positive controls; DNA (15 μg) from the patient D.B. was used as a negative control. Hybridization of probe 2 under identical conditions showed a positive signal only on the track containing DNA from D.B. (data not shown).

β -globin gene are known to cause β^0 thalassaemias with no production of cytoplasmic β -globin mRNA¹⁷. We have been unable to study the effect of this mutation on the *in vivo* splicing of the factor IX pre-mRNA in our patient because of the difficulty of obtaining liver biopsy samples, which are the source of the hepatocytes that express factor IX. However, in theory, if the incompletely spliced mRNA were translated and the protein processed normally, a truncated protein of 217 residues would be produced which extends 22 amino-acid residues from exon 9 and terminates at TGA at nucleotide 21,231 (ref. 2). In practice, there is doubt that this occurs because virtually no factor IX antigen is detectable in plasma by radioimmunoassay.

It has been possible in both α and β thalassaemias to use oligodeoxynucleotide probes to detect single base changes in genomic DNA. Here we have shown that this approach can be successfully applied to haemophilia B, both to detect a single base change in the patient and to detect the presence of the mutant allele in a heterozygote. This should allow the use of mutation-specific probes to perform prenatal and carrier diagnosis of haemophilia B in families carrying mutations that have been characterized at the molecular level. In addition, using the same techniques, it should be possible to analyse naturally occurring sequence differences such as those characterized here to the factor IX gene, which do not alter restriction enzyme cleavage sites in genomic DNA, to determine whether they are polymorphic in the normal population. If this is the case, then their use in linkage analysis should extend the range of carrier and prenatal diagnostic facility currently available for haemophilia B^{14,19}.

We thank K. Gould for the synthesis of probes 1 and 2, MRC or a Research Studentship to D.J.G.R., St John's College, Oxford, for a North Senior Scholarship to D.J.G.R. and Barbara Paxman for secretarial help. We also thank patients and physicians for blood samples.

Axoplasm extruded from the squid giant axon has been used to analyse the molecular mechanisms of intracellular vesicle transport^{1,2}. Using video-enhanced light microscopy, vesicle transport can be observed directly on individual microtubules at the edge of the axoplasm²⁻⁴. Here we report that AMP-PNP (adenyl-5'-yl imidodiphosphate), a non-hydrolysable analogue of ATP, reversibly inhibited vesicle transport. Moreover, vesicles in solution attach to the microtubules and form relatively stable complexes. AMP-PNP may produce this effect by binding to an ATP-binding site on the transport machinery, thereby stabilizing the motility complex that is normally formed by a transported vesicle, an ATPase and a microtubule. The effects of AMP-PNP on the vesicle transport system indicate that the enzymatic machinery of this system differs significantly from that of the actomyosin system or the dynein-microtubule system.

Using the extruded axoplasm model, we have begun to explore the following question: is the molecular mechanism of vesicle transport similar to the two well-characterized models of cell motility in metazoa, the actomyosin-based system in muscle^{5,6} and the dynein-based system in the axonemes of flagella and cilia^{7,8}? One basic property of both these systems is their response to changes in the concentration of ATP. When ATP is absent, myosin and dynein form stable (rigor) complexes with their motile partner (actin and the B subfibril, respectively)⁵⁻⁸. By contrast, when ATP is added to a muscle or an axoneme in rigor, the rigor complexes rapidly dissociate and the ATP is hydrolysed⁶⁻¹⁰.

Non-hydrolysable analogues of ATP, such as AMP-PNP, can be used selectively to block events in the cycle of motility which are dependent on the hydrolysis of ATP¹¹. In muscles and axonemes, AMP-PNP stabilizes those transient intermediates that occur in the motility cycle just before ATP hydrolysis⁶⁻¹⁴. AMP-PNP acts by binding specifically to the ATP binding site on myosin and dynein; and, like ATP, it tends to dissociate the actomyosin and dynein-B subfibril complexes *in vitro*¹⁰⁻¹⁴. However, myosin and dynein have a lower affinity for AMP-PNP than for ATP, and AMP-PNP is less effective than ATP at dissociating the rigor complexes¹⁰⁻¹⁴.

We have used AMP-PNP to obtain information about the transient intermediates that are formed before ATP hydrolysis in the motility cycle of vesicle transport. Perfusion of axoplasm with a physiological buffer (see Fig. 1 legend) containing 0.5-

Fig. 1 Microtubules at the periphery of the axoplasm (arrowheads). *a*, Isolated microtubules in buffer X without AMP-PNP. Vesicles in solution frequently attach and translocate along the microtubules. Arrows, examples of vesicles moving along microtubules. *b*, Microtubules in the presence of 5 mM AMP-PNP (lithium salt). In the presence of AMP-PNP, vesicles attach to the microtubules and remain stationary, producing the appearance of a 'string of pearls'. Small, medium and large vesicles are indicated by different sized arrows. In parallel experiments, Li^+ at concentrations of 1–5 mM had no effect.

Methods. In all the experiments described here, axoplasm was obtained from the medial third-order giant fibres of squid (*Loligo pealei*). Briefly, the giant fibres were tied off at each end and removed from the animal^{2,20}. After removing excess connective tissue, the fibre was rinsed in buffer X (350 mM potassium aspartate, 130 mM taurine, 70 mM betaine, 50 mM glycine, 20 mM HEPES, 12.9 mM MgCl_2 , 10 mM EGTA, 3 mM CaCl_2 , 1 mM glucose, 1 mM ATP, pH adjusted to 7.2 with KOH), blotted dry and the proximal end cut². A cylinder of axoplasm was extruded onto a coverslip, which formed the lower surface of the observation chamber². To form the side walls of the chamber, two thin spacers were placed on either side of the axoplasm. A space of ~1 mm was left between each spacer and the axoplasm, and a coverslip with spacers was gently placed on top of the axoplasm to complete the chamber. All the experimental observations began with a scan of the axoplasm to ensure that the preparation was active; then 10 μl buffer X containing 0–1 mM ATP and 0–10 mM AMP-PNP was perfused through the chamber. Movement was observed in the centre and at the periphery for 30 min or until no movement was observed. Video-microscopy was carried out using AVEC-DIC (video-enhanced differential interference contrast) microscopy using a Zeiss Axiomat microscope and Hamamatsu video equipment^{1,3}.

10 mM AMP-PNP immediately blocked the movement of vesicles on microtubules at the periphery of the axoplasm (Fig. 1). Below 0.5 mM AMP-PNP, movement was not effectively blocked.

At AMP-PNP concentrations which blocked transport, free vesicles in the solution attach normally to the peripheral microtubules but do not translocate. After 3–5 min, so many vesicles had attached to the microtubules and then remained stationary that the microtubules had the appearance of a 'string of pearls' (Fig. 1b).

Fig. 2 Effects of ATP and AMP-PNP in the presence and absence of exogenous ATP. Axoplasm was extruded as described in Fig. 1 legend. A known volume of buffer, which contained either AMP-PNP alone (circles) or AMP-PNP with 1 mM ATP added (triangles and dashed line), was perfused into the chamber. The ratio of the buffer volume to axoplasm volume was ~5:1. Vesicle movement was observed in the centre of the axoplasm and recorded every 5 min until either >95% of the vesicles had stopped moving or 30 min had elapsed. The results are plotted as a function of increasing concentration of AMP-PNP against time taken for inhibition of vesicle movement. All experiments were done in replicate with $n = 2$ –4 for each condition; vertical bars indicate s.e.m. The difference between the time to inhibition with AMP-PNP alone and with AMP-PNP + 1 mM ATP is significant for all concentrations tested at $P > 0.01$. The inset shows the same data plotted against the log of the concentration of AMP-PNP. Lines on the inset were fitted by the linear regression method and each line had a regression coefficient of $r = 0.94$. These dose-response experiments indicate that it takes ~25 min for the lowest effective concentrations of AMP-PNP (0.5 mM) to inhibit reproducibly vesicle movement in the centre of the axoplasm. Presumably, this represents the interval required for the concentrations of AMP-PNP and ATP to equilibrate between the axoplasm and the external buffer because vesicle movement stops immediately at the periphery of the axoplasm.

In the central axoplasm, vesicle movement was also inhibited by AMP-PNP². At 10 mM exogenous AMP-PNP, levels of AMP-PNP in the centre of the axoplasm reached a sufficient concentration to inhibit vesicle movement after only 2 min. At lower concentrations complete arrest of vesicle movement in the centre of the axoplasm was delayed by the time that it takes for sufficient AMP-PNP to diffuse from the external buffer into the axoplasm (Fig. 2).

AMP-PNP inhibited vesicle movement at concentrations as low as 0.5 mM, which is similar to the ATP concentration in the axoplasm. Normally, axoplasm contains ~1 mM endogenous ATP but when the axoplasm and buffer in the perfusion chamber equilibrate, the final concentration of ATP is ~0.2 mM. This concentration of ATP is sufficient to maintain normal vesicle transport for the duration of the experiment. Thus, AMP-PNP completely inhibited particle movement in the presence of ATP at a concentration that normally maintains motility. By contrast, AMP-PNP does not completely inhibit motility in muscle and axonemes when the concentration of ATP is sufficient to maintain motility.

AMP-PNP may block vesicle transport by effectively competing with ATP for the nucleotide binding site or sites in the vesicle transport machinery. To test this hypothesis, we examined the effects of adding exogenous ATP on the inhibition of vesicle movement by AMP-PNP (Fig. 2). We found that 1 mM ATP significantly delayed the inhibitory effect of AMP-PNP at all concentrations and completely blocked the inhibitory effects of 0.5 mM AMP-PNP. Moreover, the inhibitory effect of AMP-PNP on vesicle transport could be reversed by perfusion with excess ATP.

In the ATP reversal experiments, the observation chamber was first perfused with 1 mM AMP-PNP to inhibit vesicle movement and then perfused twice with 10 μl buffer containing 10 mM ATP. Vesicle movement resumed at the periphery within

Fig. 3 Schematic enzyme mechanisms for intracellular motility cycles⁷⁻⁹ comparing the actomyosin and dynein ATPase cycles (a) with the vesicle transport cycle (b). a, 'ATPase' refers to either myosin or dynein and T refers to the translocatable partners (that is, filamentous actin or the B subfibril). NTP refers to nucleotide (for example, ATP or AMP-PNP) and Pr refers to the products of ATP hydrolysis. The drive stroke for myosin and dynein occurs after step 3. b, 'ATPase' refers to the putative ATPase in the crossbridge that mediates the attachment of the translocatable vesicles (V) to the microtubules (MT)¹⁵. We propose that ATP modulates the affinity of the ATPase-vesicle complex for the substrate microtubule. This hypothesis is supported by the observation that vesicles prepared from squid axoplasm retain their motile ATPase and can translocate along flagellar microtubules¹⁷. For simplicity the scheme is drawn as if the vesicle transport ATPase has a stable association with the vesicle. However, the ATPase can apparently dissociate from the vesicle. The step at which products (Pr) are released remains to be determined in both (a) and (b). Note that the effect of the binding of nucleotide (NTP) in the actomyosin and dynein cycles (a) is the opposite of its effect in the vesicle-transport cycle (b).

1-2 min of ATP addition, and vesicles began to move in the centre of the axoplasm 10 min after ATP addition.

Based on these results, we propose that AMP-PNP operates by competitively attaching to a critical ATP binding site in the motility machinery of vesicle transport. Miller and Lasek¹⁵ have recently proposed that the critical ATP binding site is an ATPase that is located on the 16-18-nm-long crossbridges that attach the transported vesicle to its substrate microtubule. Thus, like the actomyosin system and the dynein-microtubule system, motility in the vesicle transport system may be based on an ATP-dependent crossbridge cycle.

ATP has two important functions in the crossbridge cycle of muscles and axonemes⁷⁻⁹; it provides energy for movement and reduces the affinity of the crossbridge (that is, myosin or dynein) for its motile partner (that is, actin or tubulin) (Fig. 3a). In muscle, the biochemical cycle producing movement begins with the binding of ATP to the stable actin-myosin (rigor) complex⁹ which induces a rapid release of the myosin crossbridge from actin. Myosin hydrolyses the ATP, producing an activated ADP-myosin complex that has a much higher affinity for actin than the ATP-myosin complex. When the activated ADP-myosin complex rebinds to actin, it releases its stored energy in the motile power stroke. A similar scheme has been proposed for axonemes^{7,8}.

The effects of AMP-PNP on vesicle transport suggest that the enzymatic cycle of vesicle transport differs in at least two important ways from the cycle proposed for muscle and axonemes. First, dynein and myosin ATPases are weakly inhibited by AMP-PNP, that is, AMP-PNP will not produce complete inhibition of the biochemical cycle at concentrations of ATP that support motility^{6,14}. By contrast, the vesicle transport ATPase is completely inhibited by AMP-PNP even in the presence of concentrations of ATP that readily support vesicle transport. Second, in both muscles and axonemes, nucleotide binding promotes the dissociation of the motility complex (Fig. 3a, step 1)^{6,10,13}. In contrast, AMP-PNP facilitates a stable association of vesicles with microtubules. This suggests that nucleotide binding (for example, ATP or AMP-PNP) to the vesicle-transport ATPase promotes the formation of the basic motility complex (the vesicle-crossbridge-microtubule complex; Fig. 3b, step 1), which is the opposite of the effect of nucleotide on myosin and dynein (Fig. 3a).

The scheme proposed for the vesicle-transport cycle in Fig. 3b is further supported by observations of vesicle movement in ATP-depleted axoplasm. When ATP is eliminated from squid axoplasm by conversion to AMP and pyrophosphate with the

enzyme apyrase, vesicle transport is inhibited and most vesicles are subject to a constrained brownian motion². Apparently, rigor complexes are not favoured in the vesicle-transport system in low ATP concentrations.

The structural organization of the vesicle transport system may be analogous in some respects to that of the actomyosin and the dynein-microtubule systems¹⁵⁻¹⁷. Significantly, in these three systems a crossbridge is the structural link between the stationary substrate and the translocated partner^{5,8,15}. However, although there may be structural analogies between these motile systems, the results presented here and others^{18,19} indicate that the enzymatic properties of the motile protein of vesicle transport differ significantly from the crossbridge proteins in both muscle and axonemes (that is, myosin and dynein, respectively).

Primary structure of bovine thyroglobulin deduced from the sequence of its 8,431-base complementary DNA

Luc Mercken, Marie-Jeanne Simons, Stéphane Swillens, Marc Massaer & Gilbert Vassart

Institut de Recherche Interdisciplinaire et Service de Chimie Clinique, Faculté de Médecine, Université Libre de Bruxelles, Campus Erasme, 808 route de Lennik, 1070 Bruxelles, Belgium

In mammals, an adequate supply of thyroid hormones is essential for normal growth and neurological development. The biosynthesis of thyroid hormones involves an iodinated precursor protein, thyroglobulin, which may be considered an extreme example of a pro-hormone¹. Thyroglobulin is a dimeric glycoprotein of relative molecular mass (M_r) 660,000 (660K), which is secreted by the thyrocyte and stored in the lumen of the thyroid follicle. The hormonogenic reaction is extracellular, and involves iodination of tyrosyl residues of thyroglobulin and the intramolecular coupling of a subset of these into thyroxine (T_4) and triiodothyronine (T_3), which remain part of the polypeptide chain. Secretion of hormones results from the endocytosis of thyroglobulin followed by its complete hydrolysis in lysosomes. Considering that the maximum yield of hormones is ~6-8 per 660K protein², the whole process is apparently wasteful. However, the efficiency of thyroglobulin as a thyroid hormone precursor is extremely high when the supply of iodine is short; in such conditions, almost all the iodine incorporated is found in iodothyronines³. Hence it is suggested that the thyroglobulin structure has evolved to allow for the preferential and efficient iodination and coupling of the hormonogenic tyrosines. Here we report the complete primary structure of bovine thyroglobulin, derived from the sequence of its 8,431-base-pair complementary DNA. The 2,769-amino-acid sequence is characterized by a pattern of imperfect repeats derived from three cysteine-rich motifs. Four hormonogenic tyrosines have been precisely localized near the amino and carboxyl ends of the protein.

The complete nucleotide sequence of bovine thyroglobulin messenger RNA (Fig. 1) was obtained by sequencing six recombinant plasmids containing 99% of its cDNA⁴ and one genomic

[illegible]

Fig. 1 Sequence of thyroglobulin cDNA and the deduced primary structure of the protein. Nucleotides are numbered (on the left of the figure) from the ATG initiation codon. The deduced amino acids are numbered from the amino-terminal asparagine of the mature protein. The polyadenylation signal⁸ is underlined. The putative *N*-glycosylation sites (Asn-X-Ser/Thr) and the tyrosine residues involved in hormonogenesis are underlined and overlined, respectively.

Methods. Six recombinant plasmids⁴ and one genomic DNA fragment (G. de Martynoff *et al.*, in preparation) were used as starting material. Subcloning in phage M13 vectors²⁴ and generation of overlapping fragments with DNase were performed as described in ref. 25. The dideoxy chain termination method²⁶ and buffer gradient gels²⁷ were used for DNA sequence analysis. Confidence was obtained by reading each nucleotide on both DNA strands. The overlapping recombinant plasmids⁴ differ at two positions: nucleotide 4,585 is A in pbTg 1.9 and G in pbTg 4.7 (changing amino-acid 1,510 from Ser to Gly), and nucleotide 7,141 is G in pbTg 4.7 and A in pbTg 2.5 (changing amino-acid 2,362 from Val to Met). These differences may reflect sequence polymorphism. However, an error in the reverse transcriptase reaction cannot be excluded.

However, an error in the reverse transcriptase reaction cannot be excluded.

Fig. 2 Internal homology in thyroglobulin primary structure. The three types of homologous domains (given in the one-letter code) are aligned. Insertions or deletions have been introduced to maximize homology. Conserved amino acids are boxed according to the following rule: for type I repeats, the amino acids should be present at least five times; for type II and III repeats, at least twice. Residues showing no conservation between the domains are represented by numbers. Homologies in Cys positions between domains IIIa and IIIb are indicated by broken lines. Localization of the domains is shown on the right; the numbering is as in Fig. 1.

DNA fragment containing the 5'-terminal portion of the message (G. de Martynoff *et al.*, in preparation). Partial nucleotide sequences have been reported for three species⁵⁻⁷ but they do not exceed 3,000 bases long. The general organization of the mRNA sequence is as follows: a 41-nucleotide 5'-untranslated segment precedes an open reading frame of 8,307 bases. To our knowledge, this represents the longest coding sequence determined to date. The 3'-untranslated segment is 83 bases long and contains the canonical AATAAA polyadenylation signal⁸.

As judged from the nucleotide sequence, a 19-amino-acid signal peptide is followed by 2,750 residues, constituting a polypeptide of expected M_r 302,253; this value is in perfect agreement with the M_r obtained for the translation product of thyroglobulin mRNA *in vitro*⁹ or in *Xenopus* oocyte¹⁰ and with the M_r of 330,000 for the glycosylated protomer¹¹. The amino-acid composition of the protein agrees with published results (not shown). In particular, despite their role in hormonogenesis, the number of tyrosine residues (72, that is, 2.5%) does not deviate significantly from the average observed in a protein data bank (3.3%; ref. 12). The sequence contains 15 potential acceptor sites for *N*-glycosylation (Fig. 4), which represents a slight excess compared with the 20 chains characterized in the mature dimeric protein¹³.

When analysed for the presence of internal homology, the protein sequence shows a striking repetitive pattern involving three types of cysteine-containing motifs (Fig. 2). The type I motif is repeated 10 times between positions 13 and 1,190; it extends over ~60 amino acids and contains 24 highly conserved residues, including six cysteines. Sequences of variable length, unrelated to the motif, interrupt some of the repeats at fixed positions (Fig. 2). Preliminary data indicate that the positions of these insertions correlate with the borders of exons (J. Parma, in preparation). The type II motif is much shorter (17 amino acids) and is only repeated three times between positions 1,439 and 1,486. The type III motif may be subdivided into two subtypes (IIIa, IIIb; Fig. 2), which display a similar pattern of cysteine residues. Both subtypes are repeated twice in tandem, between positions 1,586 and 2,111. A third copy of motif IIIa is found further downstream (Fig. 4). Over 75% of the thyroglobulin sequence is thus involved in some kind of repetitive structure, clearly indicating that this exceptionally large protein evolved from the serial duplication of a limited number of building blocks. Interestingly, the last 600 residues at the carboxyl end show no internal homology, are poor in cysteine and contain a cluster of tyrosines of which three are hormonogenic (see below and Fig. 4).

Fig. 3 Hormonogenic domains in thyroglobulin. The hormone-containing domains identified to date in various species are represented by the one-letter code and are aligned for maximum homology. The capital letters correspond to amino acids occurring at least twice in different species. The four hormonogenic tyrosines are boxed and their positions in the protein are indicated. *a*, *c*, *g*, the peptide sequences derived from the present study; *b*, the four identical hormone-containing peptides determined from bovine, human, ovine and porcine thyroglobulin^{17,28,29}; *d*, the sequence of three peptides obtained from porcine thyroglobulin, named *b*₁Ad₃, T6 and *b*₁B in ref. 18; *e*, *i*, protein sequence derived from a partial rat cDNA sequence⁷; *f*, a tryptic peptide, isolated from human thyroglobulin, containing a glycosidic chain attached to the asparagine residue³⁰; *h*, sequence of a hormone-containing peptide isolated from porcine thyroglobulin¹⁹.

Fig. 4 Schematic representation of the thyroglobulin precursor. For clarity, a space has been introduced between the homologous domains even when they are contiguous in the protein (see Fig. 2). The tyrosine and thyroid hormone residues are represented by short and longer bars, respectively.

The sequence organization of thyroglobulin (Fig. 4) is reminiscent of the structure of some other large polypeptides, including the epidermal growth factor (EGF) precursor¹⁴, EGF receptor¹⁵ and low-density lipoprotein receptor¹⁶. Although there exists no direct sequence homology between thyroglobulin and these proteins, they probably share an analogous evolutionary history and may have similar three-dimensional structures.

Four tryptic peptides containing thyroid hormones have been isolated from thyroglobulin of various species and sequenced¹⁷⁻¹⁹. A systematic search for homologous peptides in our sequence allowed the identification and precise localization of all four hormonogenic tyrosines (Figs 3, 4). Two of these map at subterminal positions (residues 5 and 2,748); they correspond to sites involved preferentially in the synthesis of T₄ and T₃, respectively^{17,19}. The other two sites are closely linked around position 2,560. The amino-terminal domain is adjacent to the first, type I, repeat and might even share sequence characteristics with it⁵. In contrast, the three other hormonogenic tyrosines map in the non-repeated carboxy-terminal segment (Fig. 4). Comparison of the sequences surrounding the hormonogenic residues reveals no clear homology except for the presence of at least one charged amino acid (Fig. 3) and some clustering of tyrosines (Fig. 4)—the significance of this observation awaits the identification of the donor tyrosine involved in the coupling reaction.

Compilation of the sequences of the hormonogenic segments presently available shows a remarkable conservation of the amino-terminal domain (Fig. 3). It has been reported that as much as 50% of the thyroxine in mature thyroglobulin may originate from this domain²⁰. Although less information is available for the other hormonogenic domains, they do not display the same degree of sequence conservation (Fig. 3). Given these considerations, it is possible that the amino-terminal region of thyroglobulin has an important role in hormonogenesis. It is noteworthy, in this context, that a 10K amino-terminal peptide is cleaved from the protein during the hormonogenic process²¹.

The chemical or enzymatic reactions responsible for this phenomenon are unknown; it must be quite specific, however, as the carboxyl terminus of the 10K peptide could be unambiguously determined and was readily localized (Gln 80) in a partial protein sequence²².

Knowledge of the primary structure of thyroglobulin should provide the basis for studying the structure-function relationships of the hormonogenic process *in vitro*, in reconstructed synthetic systems, and should help to elucidate the molecular basis for genetic defects of thyroglobulin production²³.

We thank Dr J. E. Dumont for his continuous support and for critical reading of the manuscript, and Mrs D. Leemans for preparation of the manuscript. This study was supported by grants from the Ministère de la Politique Scientifique, NIH (21732), FRSM, IRSIA and ARBD.

Ethylation interference and X-ray crystallography identify similar interactions between 434 repressor and operator

Frederic D. Bushman, John E. Anderson, Stephen C. Harrison & Mark Ptashne

Fairchild Biochemistry Building, Harvard University, 7 Divinity Avenue, Cambridge, Massachusetts 02138, USA

In the crystal structure of a repressor-operator complex (the 434 repressor DNA-binding domain and its 14-base pair (bp) operator), Anderson *et al.*¹ elsewhere in this issue identify six positions of likely contact between repressor protein and phosphates of the DNA backbone. At each of these positions, electron densities of protein and DNA merge. Experiments presented here indicate that intact 434 repressor approaches these phosphates very closely when it is bound to DNA in solution. Specifically, when any one of these phosphates is ethylated², repressor cannot bind to the modified operator. We also identify another position where ethylation has

Fig. 1 Ethylation interference analysis of 434 repressor-operator interactions. *a*, Results for top strand; *b*, results for bottom strand. Lane 1, DNA bound by repressor; 2, DNA not bound by repressor; 3, ethylated unseparated control. In *a* and *b*, bands depleted in lane 1 and enriched in lane 2 relative to the control in lane 3 indicate ethylphosphates that interfere with repressor binding. *c*, Ethylphosphates that interfere with repressor binding aligned with the 434 operator sequence. Filled triangles, strong interference; hatched triangles, weaker interference.

Methods. A double-stranded consensus 2-fold-symmetric 434 operator of identical sequence to that used by Anderson *et al.*¹ with single-stranded *SalI* ends was generated by self-annealing of an oligonucleotide of sequence 5' TCGAACAATATATATTGT 3' (made on an Applied Biosystems Model 380A DNA synthesizer). This fragment was treated with T4 kinase (BRL) and ATP, then cloned using standard methods⁷ into the unique *SalI* site within the *lacZ* gene of pEMBL8- (ref. 8) to generate pFB37. Because insertion of the oligonucleotide destroys the *SalI* site, vectors without the insert in the ligation product could be linearized by digestion with *SalI* and hence eliminated during transformation. The 18-bp insertion preserves the *lacZ* translational reading frame by inserting 6 codons, none of which are translational stops. Plasmids with cloned operators could therefore be identified by transforming *Escherichia coli* strain JM101 (ref. 9) (phenotypically LacZ-), plating on X-Gal¹⁰ and picking blue Lac Z+ colonies. Plasmids containing single operators were identified by DNA sequencing¹¹ and cleaved at the unique *EcoRI* site. Cleaved plasmids were 3'-labelled (top strand) with DNA polymerase I large fragment (NEB) and [α -³²P]dATP (NEN), or 5'-labelled (bottom strand) by successive treatments with bacterial alkaline phosphatase (Boehringer) and T4 kinase and [γ -³²P]ATP (ICN; reactions as in ref. 7). After cleavage with *HindIII*, the labelled operator-containing fragment was isolated by electrophoresis on a 5% polyacrylamide gel, excision of the desired band and electroelution in 0.2× TAE buffer⁷. After filtration (Milex 0.45- μ m HA filters), phenol extraction, ether extraction and ethanol precipitation, DNA was ethylated with ethylnitrosourea (Sigma) as described². Ethylnitrosourea-treated DNA ($\sim 5 \times 10^{-8}$ M) was incubated at 4°C with 2×10^{-7} M 434 repressor (isolated as described previously¹²) in 50 mM KCl, 2 mM MgCl₂, 10 mM Tris pH 7.4, 0.5 mM EDTA, 1 mM dithiothreitol, 50 μ g ml⁻¹ bovine serum albumin and 5% glycerol. Repressor-operator complexes were separated from unbound DNA that contained ethylations interfering with repressor binding by polyacrylamide gel electrophoresis³⁻⁵. Bound and unbound fractions were excised from the gel and purified as described above. Ethylated DNA fragments were cleaved at phosphotriesters by heating in alkali², prepared for electrophoresis as described³ and analysed on a 10% sequencing gel. Ethylation cleavage products were aligned with the sequencing ladder by correcting down to the nearest base (see ref. 2 for discussion). Alignment of a 5'-labelled sequencing band with a 5'-labelled ethylation cleavage product identifies the phosphate 5' to that base; alignment of a 3'-labelled sequencing band with a 3'-labelled ethylation cleavage product identifies the phosphate 3' to that base.

a significant but less dramatic effect on repressor binding, and note that in the structure, repressor closely approaches this phosphate. Our results strongly support the idea that the interactions between protein and the DNA phosphate backbone in the crystallized complex¹ are the same as those made by intact repressor to operator DNA in solution. In addition, our results suggest that DNA is slightly bent by repressor binding.

Phosphates of the 434 operator which, when ethylated, interfere with 434 repressor binding were identified by the method of Siebenlist and Gilbert² (modified as described by Hendrickson and Schleif³, see Fig. 1 legend). Briefly, the 2-fold-symmetric consensus 434 operator used by Anderson *et al.*¹ was cloned on a plasmid, end-labelled and ethylated such that each DNA molecule had an average of no more than one ethylphosphate. Purified ethylated fragment was incubated with excess 434 repressor, then operators bound to repressor were separated from the unbound operators by electrophoresis³⁻⁵. The unbound DNA molecules contain ethyl groups that prevent binding. Bound and unbound DNA fragments were isolated, cleaved at sites of ethylation and examined by electrophoresis on a polyacrylamide sequencing gel. Each band on the gel is generated by cleavage at a specific ethylphosphate. Bands enriched in the unbound fraction and depleted in the bound fraction indicate phosphates at which ethylation inhibits repressor binding.

Ethylation at any of three phosphates found 5' to bases -1, 9, and 10 on each strand prevents binding at the repressor concentration used here (compare lanes 1 and 2, Fig. 1*a, b*). Anderson *et al.*¹ show that these phosphates lie near residues Asn 16 and Gln 17 at the N-terminus of helix α 2 (phosphate -1); and Lys 40, Arg 41 and Arg 43 (phosphates 9 and 10). Ethylation of a fourth phosphate, 5' to base 11, has a significant but weaker effect on binding (hatched triangles in Fig. 1). In our interpretation of the structure, this phosphate is positioned within reasonable hydrogen-bonding distance of the γ -O of Ser 30. Thus, there is excellent agreement between the results of these chemical probe experiments and the co-crystal structure. The four phosphate contacts are symmetrically disposed about the centre of the operator (Fig. 1*c*) on one face of the B-DNA helix (Fig. 2).

Ethylation of a DNA phosphate removes the negative charge and adds a group with a van der Waals radius of ~ 4.5 Å. Both steric and charged-group effects can therefore contribute to its influence on binding. Model building with straight DNA shows that with the relationship of DNA and protein seen in the crystal, the side chains of Asn 16 and Gln 17, the only residues near

Fig. 2 Phosphates of the 434 operator at which ethylation reduces affinity for 434 repressor. Positions of strong ethylation interference are symbolized by filled circles and weaker interferences by hatched circles on a B-DNA helix. The operator centre of symmetry is indicated with a small filled circle.

the -1 phosphate, are too far from the DNA backbone for hydrogen-bond formation (Fig. 3a). If the DNA is bent to a radius of curvature of ~ 100 Å, then a hydrogen bond to the -1 phosphate can readily be made (Fig. 3b). Other small deformations could have a similar effect. An additional contribution to binding might come from favourable interaction between the partial positive charge on the N-terminus of helix $\alpha 2$ and the negative charge on the phosphate⁶. Based on the observed significance of the interaction at the -1 phosphate, we propose an explanation for some aspects of the crystal structure. In the co-crystal, 14-bp operators, each bound by a dimer of repressor DNA-binding domain, pack end-to-end to form rods. Each

Fig. 3 Interaction of Asn 16 and Gln 17 with straight and bent DNA showing the α -carbon backbone of λ -repressor residues 30–60 (ref. 13), positioned as described by Anderson *et al.*¹, with the side chains of Asn 16 and Gln 17 of 434 repressor extending toward the DNA. In *a*, straight B-DNA was constructed by extending the double helix of the model DNA that best fits the electron density of one 14-bp operator¹. The amino nitrogens of the Asn 16 and Gln 17 side chains are both >5 Å from the oxygens of the -1 phosphate, which is too far for hydrogen-bond formation. In *b*, B-DNA with a slight right-handed supertwist, generated as described by Anderson *et al.*¹, was positioned so that 14 bp of the modelled DNA gave the best fit to the electron density of one 14-bp operator. The side-chain amino groups of Asn 16 and Gln 17 are separated from the phosphate oxygens by ~ 3 Å, a typical hydrogen-bond length.

14mer is tilted slightly and displaced laterally with respect to the next, so that the 3' terminal base on each strand does not stack on the adjacent operator. A repressor monomer bound to a given 14mer reaches over to an adjacent 14mer to make the -1 phosphate contact, and the DNA structure deviates from regular B-like conformation in this region. We imagine that the tilting and displacement of the 14mers, and possibly the local departure of the DNA backbone from canonical B-form, are consequences of crystallization using discrete fragments rather than continuous DNA. We believe that these effects occur in order to accommodate the -1 phosphate interaction, which in continuous DNA seems to require a gentle bend.

Photochemical transmembrane electron transfer processes are an integral part of natural photosynthetic solar energy conversion and are also central to the design of biomimetic energy conversion schemes^{1–6}. Here we report the synthesis and membrane-associated photoelectrochemical properties of carotenoporphyrin–quinone triad (I), a compound containing a photochemically active porphyrin and electron donor and acceptor moieties, and with the molecular architecture necessary to span a phospholipid bilayer. On excitation of compound I by visible light, charge is separated across a planar phospholipid bilayer membrane (BLM) in an intramolecular step; in the presence of suitable electron donor and acceptor species in the aqueous phases, a steady-state photocurrent is observed in an external circuit bridging the BLM. Artificial membranes containing I thus mimic key features of the photodriven transmembrane electron transfer processes characteristic of photosynthetic organisms.

Fig. 1 *a*, Schematic diagram of a BLM cell for photoelectrical measurements: 1, side 1 containing oxidant ($\text{Fe}(\text{CN})_6\text{K}_3$), phosphate buffer and NaCl; 2, side 2 containing reductant (sodium ascorbate), phosphate buffer and NaCl; 3, Ag/AgCl electrode; 4, Keithley model 427 current-to-voltage converter; 5, Tektronix digital storage oscilloscope; 6, 1-mm-diameter orifice in thin Teflon divider; 7, laser; 8, shutter; 9, cell machined from block of Teflon. *b*, Schematic diagram showing the postulated arrangement of triads in the phospholipid bilayer. Note that triad I (labelled Q) is shown at the aqueous interface on side 1 and triad II (QH_2) at the interface on side 2.

Photodriven charge separation in single-phase solution in compounds similar to I has been shown to be a two-step process involving electron transfer from the photoexcited porphyrin singlet state to the attached quinone, followed by electron transfer from the carotenoid to the porphyrin radical cation⁷⁻¹⁰. The resulting species, $\text{C}^{++}-\text{P}-\text{Q}^{--}$, is formed within ~ 100 ps of excitation and has a solvent-dependent lifetime on the micro-second timescale.

Triad I and its related forms II and III (see above) were synthesized by routes similar to those used previously^{7,11}. Their structures were verified using 500-MHz ^1H -NMR spectroscopy¹².

The photoelectrochemical experiments were carried out in the apparatus described previously¹³ (see Fig. 1*a*). The triad was dissolved in the appropriate membrane-forming solution (see Fig. 2 legend) and a small drop applied to the orifice in the Teflon divider. The phospholipid solution gradually thinned and formed a bilayer, as detected by coulometric measurements¹³. The current flowing through the cell, and therefore through the BLM, was detected as a function of time and displayed on a digital oscilloscope. In a typical experiment with triad I in the membrane, 1×10^{-2} M $\text{Fe}(\text{CN})_6\text{K}_3$ was dissolved in the aqueous phase on side 1 and 1×10^{-2} M ascorbic acid was placed on side 2. In the dark, no significant current was observed. However, irradiation of the BLM with 600-nm light from the laser produced an immediate photocurrent (Fig. 2). Typically (Fig. 2*a*), the photocurrent consisted of a transient component that rose with the opening time of the shutter (< 1 ms) and quickly decayed to a steady-state value (typically 50–500 pA). The peak of the transient current and the steady-state value varied considerably between samples. Generally, there was a strong positive correlation between the extent of bilayer formation, as estimated from the coulometric measurements, and the magnitude of the photocurrent. Moreover, on average, photocurrents obtained when the membrane-forming solution was prepared with hexadecane were larger than those when decane was used. This observation is consistent with the fact that solvents comprising hydrocarbon of longer chain length yield thinner membranes¹⁴. Figure 2*b* shows a photocurrent in which the transient component was not observed; such signals were less common than the first type, but occurred more frequently when the aqueous phases were at low pH and when the membranes were more than 10 min old and very thin (that is, when hexadecane was used as the solvent).

The currents discussed above are clearly the result of photo-induced electron transport across the phospholipid bilayer. We propose the following explanation for the results. The triad is a rod-like, amphipathic molecule that would be expected to lie in the bilayer as shown in Fig. 1*b*. The hydrocarbon-like carotenoid moiety (which extends ~ 39 Å from the porphyrin centre) should be well anchored in the low-dielectric membrane interior and should be aligned to some extent with the fatty-acid chains. The polar dipyrrolic porphyrin moiety, on the other hand, should lie in the higher-dielectric region near the head groups.

This is particularly the case at pH 3, where one would assume that the dipyrrolic porphyrin was positively charged. Because of its short connecting link to the porphyrin, the quinone must also reside near the membrane surface. In addition, the membrane is asymmetric by virtue of the fact that even though the triad is added to the membrane-forming solution in the hydroquinone form II (because it is more soluble), the addition of $\text{Fe}(\text{CN})_6\text{K}_3$ to the solution on side 1 (Fig. 1*a*) converts the molecules having their hydroquinone moieties at the side 1 aqueous interface to the quinone form. Those molecules having their hydroquinone moieties at the side 2 interface remain in that oxidation state. (This interfacial oxidation was demonstrated in bulk two-phase mixtures of the membrane-forming solution and aqueous ferricyanide, using chromatographic detection. No detectable decomposition of the pigments in such bulk mixtures was noted even after several hours of contact.)

Irradiation of a triad quinone I in such a bilayer is postulated to produce the $\text{C}-\text{P}^{++}-\text{Q}^{--}$ charge-separated state, and ultimately the $\text{C}^{++}-\text{P}-\text{Q}^{--}$ state, as observed in similar monophasic systems⁷⁻¹⁰; this would lead to a quinone radical anion near the aqueous interface on side 1, and a carotenoid radical cation in the interior of the bilayer. The quinone radical anion then donates an electron to ferricyanide to regenerate the neutral quinone, and the carotenoid radical cation, which can nearly span the bilayer, can accept an electron from the ascorbate on side 2 to regenerate the neutral carotenoid. The net result is the vectorial transfer of an electron from side 2 to side 1 and the regeneration of the triad photocatalyst. The charge separation across the membrane is countered by electron flow through the electrodes and detected as current in the external circuit.

There are several lines of evidence supporting the above interpretation of the experimental results. First, laser-flash photolysis of phosphatidylserine (or ethanolamine) liposomes containing compound I with 590-nm light resulted in a transient species having a maximum wavelength (λ_{max}) of 970 nm; the spectrum of this transient confirmed that it was indeed the

Fig. 2 Transmembrane photocurrents observed on irradiation of triads in BLM systems. *a*, pH 6.5, peak current 200 pA, 1×10^{-2} M ascorbate in side 2 and 1×10^{-2} M $\text{Fe}(\text{CN})_6\text{K}_3$ in side 1; *b*, pH 2.7, current 150 pA, same redox couples as in *a*; *c*, pH 5, peak current 29 pA, oxidizing couple as in *a*, no reductant in side 2, hexadecane as the solvent; *d*, triad III, noise peaks are ~ 5 pA, conditions as in *a*. The membrane-forming solutions used phosphatidylserine or phosphatidylethanolamine (3 mg), decane (100 μl) and ~ 0.05 mg of triad. In each case the membrane showed substantial thinning, as measured by coulometric response, greater than $5 \text{ G}\Omega$ d.c. resistance, and a dark current of < 5 pA. Each aqueous phase contained 0.1 M NaCl, 1×10^{-3} M phosphate buffer and a freshly prepared Ag/AgCl electrode. The sign of the observed currents is consistent with a negative charge carrier flowing from side 2 to side 1 through the bilayer. In these experiments there was no pH gradient (ΔpH) across the membrane. For *a*, *b* and *c*, triad II was used in the membrane-forming solution as described in the text.

carotenoid radical cation. Thus, the postulated charge separation does occur in the phospholipid bilayer. Furthermore, when the electron donor (ascorbate) was omitted from side 2, large transient photocurrents were observed on illumination, but a steady-state photocurrent was never detected (Fig. 2c). Similarly, no steady-state current was observed in the absence of ferricyanide. In addition, no transmembrane electrical response was detected for triad III in the conditions used for I

(Fig. 2d). In III, the hydroquinone moiety is protected as the dimethyl ether, and formation of the intramolecular charge-separated state is precluded. These three control experiments confirm the involvement of the transmembrane charge-separated state of triad I and the aqueous-phase redox couples in the observed steady-state photocurrents.

A final piece of evidence concerns the turnover number of the triad in the BLM. If the proposed scheme is indeed correct, then each triad I molecule should be capable of transporting many electrons across the bilayer. At the excitation wavelength of 600 nm, the porphyrin absorption cross-section is $\sim 1.7 \times 10^{-17} \text{ cm}^2$ per molecule and the laser intensity was $\sim 3 \times 10^{18}$ quanta per s cm^2 , yielding ~ 50 excitations per s molecule. From the composition of the membrane-forming solution, there are an estimated 10^{10} molecules per BLM and therefore 5×10^{11} excitations per s in the BLM. At a quantum yield of $\sim 10\%$ (refs 7–10), this corresponds to a photocurrent of $\sim 4 \text{ nA}$, a value recorded in some of the BLM experiments. Although very approximate, this result is certainly consistent with a steady-state process having a high turnover number and capable of operating for many seconds.

Note that this example of transmembrane electron transfer is essentially the light-driven catalysis of the thermodynamically spontaneous oxidation of ascorbate by ferricyanide ion. None of the intramolecular redox potential of the charge-separated state $\text{C}^{++}-\text{P}-\text{Q}^{\cdot-}$ is conserved as transmembrane chemical potential. However, photocurrents opposing the applied electrical potential were observed even when side 1 was 100 mV negative to side 2. The judicious choice of redox couples and a properly asymmetrized membrane should ultimately make it possible to achieve net energy conservation in this system.

In photosynthetic membranes, carotenoids prevent the sensitization of oxygen by chlorophyll triplet-state species and thereby perform a photoprotective function^{15,16}. These carotenoporphyrin triads have sufficient electronic coupling between the carotene and porphyrin moieties¹¹, via the amide linkage, to mediate extremely rapid triplet-triplet energy transfer ($\text{C}-\text{P}-\text{Q} \rightarrow {}^3\text{C}-\text{P}-\text{Q}$)⁹. Therefore, even though excitation of the hydroquinone triads results in a high yield of porphyrin triplet, energy transfer to the attached carotenoid occurs on the nanosecond timescale and precludes singlet oxygen formation. These artificial membranes are thus photoprotected in precisely the same way as native photosynthetic membranes.

The photodriven charge separation by carotenoporphyrin-quinone triads across artificial membranes, as demonstrated here, serves as a paradigm for many transmembrane electrochemical events in energy-transducing biological membranes, and will allow detailed investigations of photodriven charge separation across both chemical and electrical potentials, which should in turn lead to a better understanding of photosynthetic energy conversion.

Hydrogen bonding in enzymatic catalysis analysed by protein engineering

Tim N. C. Wells & Alan R. Fersht

Department of Chemistry, Imperial College of Science and Technology, London SW7 2AY, UK

Two historic publications have suggested that enzymes can utilize the binding energy with their substrates to increase the rate of chemical catalysis—a concept termed strain^{1,2}. Specifically, the structure of an enzyme was described as complementary to the structure of the transition state of its substrate rather than to that of the unreacted substrate, so that the substrate would tend to be distorted on binding to the enzyme. The current understanding of strain does not require such distortion. Instead, it is thought that there are groups on the enzyme which interact better with the transition state than with the unaltered substrate, an arrangement known as differential binding of substrates and transition states³. The improvement in binding energy caused by going from substrate to transition state lowers the activation energy of the reaction and so increases the catalytic rate. Here we report direct evidence in support of this notion. Rapid reaction kinetics on mutants of a tyrosyl-transfer RNA synthetase produced by protein engineering show that certain hydrogen-bonding side chains some distance from the reacting bonds of the substrate bind to ATP preferentially in the transition state of the reaction rather than in the unreacted state. In this way, the binding energies of the interactions are used primarily to lower the apparent activation energy of the chemical steps rather than to enhance binding.

The hypothesis of better binding in the transition state has been tested using substrates and inhibitors with varying structures. Two lines of supporting evidence have been adduced from classical enzyme kinetics³. First, transition-state analogues, which usually mimic the changes in geometry about the bonds that are being broken and made in the reaction, often bind between 10² and 10⁴ times more strongly than the original substrates. Second, experiments on proteases with broad specificity show that additional groups on a substrate can lead to an increase in k_{cat} rather than stronger binding. These experiments suggest that groups on the substrate that are far from the seat of reaction can alter the catalytic rate. Many of the substrates

Fig. 1 Side chains of the tyrosyl-tRNA synthetase that form hydrogen bonds with tyrosyl adenylate (courtesy of D.M. Blow and P. Brick).

used in these studies, however, differ greatly from each other or from the specific substrates, and the results may arise simply from the nonproductive binding of the smaller substrates³.

The advent of protein engineering allows the idea of differential binding of transition states and substrates to be tested directly by varying the structure of the enzyme. An amino-acid side chain that interacts with the substrate can be altered to remove the interaction. If the side chain binds equally well with the substrate in both the ground and transition states, then removal should raise the dissociation constant K_S and not affect k_{cat} . Conversely, if the side chain binds the substrate only in the transition state, then removal should leave K_S unaltered and just lower the value of k_{cat} . Importantly, just one interaction out of many with the substrate may be changed at a time so that artefacts associated with a change of mode of binding of the substrate will be minimized. The contributions of individual interactions to differential binding energies are not known and this approach enables them to be quantified.

Genes of mutant tyrosyl-tRNA synthetases (from *Bacillus stearothermophilus*), which have had the relevant hydrogen-bonding groups removed, have been generated for use in experiments to determine the role of hydrogen bonding in biological specificity⁴. Values of k_{cat} and K_M for tyrosine and ATP for the activation reaction (equation (1)) were measured by pyrophosphate

exchange. Unfortunately, because of the complex kinetics, the values of k_{cat} and K_M for pyrophosphate exchange are composite

Table 1 Activation of tyrosine by tyrosyl-tRNA synthetases

Enzyme	k_3 (s ⁻¹)	K'_S (ATP) (mM)	K_S (Tyr) (μM)
Wild type	38	4.7	12
Δ(321-419)*	34	5.2	12
Tyrosine binding-site mutants			
Tyr → Phe 34	35	4.4	29
Tyr → Phe 169*	35	4.6	1,320
ATP binding-site mutants			
Cys → Ser 35	4.7	4.8	8
Cys → Gly 35	4.0	4.5	11
His → Gly 48	9.9	9.9	23‡
Thr → Ala 51	75	4.7	12

Experiments performed at 25 °C at pH 7.78 (144 mM Tris-HCl) in the presence of 10 mM free MgCl₂. k_3 , Rate constant for the formation of E.Tyr-AMP obtained by stopped-flow fluorimetry⁸, with standard error ±5%. K'_S (ATP) dissociation constant of ATP from the E.Tyr.ATP complex, determined as for k_3 ; K_S (Tyr), dissociation constant of Tyr from the E.Tyr complex obtained from equilibrium dialysis⁸.

* Truncated enzyme lacking the tRNA binding domain (residues 320-419)⁹.

† Mutation on truncated enzyme with the reference enzyme being the truncated wild-type enzyme.

‡ This value is abnormally high and may be caused by a loss of an electrostatic interaction with His 48.

Table 2 Apparent binding energies of side chains to substrates and to transition states

Side chain	Binding energy with substrate* (kcal mol ⁻¹)	Binding energy with transition state† (kcal mol ⁻¹)
Tyrosine binding site		
Tyr 34 —OH	-0.52	-0.57
Tyr 169 —OH	-2.58	-2.58
ATP binding site		
Cys 35 —SH	-0.03	-1.21
His 48 —imidazole	-0.44	-1.24
Thr 51 —OH	0.00	+0.40

* Calculated from $\Delta G = -RT \ln K_{mut}/K_{wt}$, where K is the relevant dissociation constant of the substrate and mut and wt refer to mutant and wild-type enzymes respectively.

† Calculated from $\Delta G = RT \ln (k_3/K)_{mut}/(k_3/K)_{wt}$.

Fig. 2 Gibbs free-energy profiles for the formation of tyrosyl adenylate (E.T-A) by wild-type enzyme (---) and the mutant Cys→Gly 35 (—) (equation (3)). The rate constants for the formation of E.T-A and the transition state E.T-A* are taken from Table 1.

The reverse rate constant k_{-3} (16 s^{-1} for wild type, 33 s^{-1} for mutant) and dissociation constant for pyrophosphate, K_{PP} (0.61 mM for wild type, 0.63 mM for mutant) were measured by stopped-flow fluorimetry⁷. Free energies were calculated from the standard equations using a standard state of 1 M for tyrosine (T), ATP (A) and pyrophosphate.

values containing rate and equilibrium constants for the pyrophosphorolysis reaction. These data thus gave no conclusive evidence on the interconversion of binding and chemical activation energies. Values for k_3 and the dissociation constants (K_S and K'_S) in equation (2) can, however, be measured

directly by stopped-flow fluorimetry⁵ and equilibrium dialysis (Table 1). From these values, free-energy contributions to binding and catalysis for individual groups can be calculated using the standard equations³ (Table 2).

The residues that were mutated are all in the binding site of the enzyme, but are not directly involved in bond making and breaking (Fig. 1). Removal of side chains that bind to tyrosine (Tyr→Phe 34 and Tyr→Phe 169) does not significantly alter k_3 but increases the dissociation constant of tyrosine from the $E \cdot \text{Tyr} \cdot \text{ATP}$ complex (Table 1). The hydroxyl moieties of Tyr 34 and Tyr 169, therefore, can be assumed to interact equally well with tyrosine in its unreacted form and in the transition state of the reaction. The binding energies of the -OH groups of Tyr 34 and Tyr 169 with the substrate and transition state are readily calculated³ and are seen to be nearly identical (Table 2).

In contrast, removal of side chains that interact with ATP causes significant changes in k_3 but, apart from His→Gly 48, hardly affects the value of K'_S for ATP. Mutation of Cys 35 to Gly 35 or Ser 35 leads to a 10-fold lowering of k_3 with no significant change in K'_S . Changing His→Gly 48 results in a mixture of effects, including a fourfold lowering of k_3 and a twofold increase in K'_S . Mutation of Thr→Ala 51 leads to a twofold increase in k_3 with no discernible effect on K'_S for ATP. This result is entirely consistent with the earlier proposal from structural observations and steady-state kinetic measurements that the bond between Thr 51 and the ribose ring oxygen is long and weak and contributes no binding energy^{5,6}. As the value of k_3 is increased on deletion of this bond, it must be even longer and weaker in the transition state. (The presence of an alanine at position 51 gives a more active enzyme, and it is intriguing

that the tyrosyl-tRNA synthetase from *Bacillus caldotenax*, which is 99% homologous with that from *Bacillus stearothermophilus*, does have alanine at position 51; ref. 7).

Thus, the side chains of residues 35, 48 and 51 probably have different interaction energies with ATP depending on whether it is in its unreacted form or its transition-state structure. The differences could arise from two effects, or a mixture of the two: (1) an unfavourable interaction in the enzyme-substrate complex that is relieved on formation of the transition state (substrate destabilization); and (2) an interaction that is not properly made in the enzyme-substrate but is realized in the enzyme-transition state complex (transition-state stabilization). We have shown by construction of the full free-energy profile for the formation of tyrosyl adenylate (Fig. 2) that the side chain of Cys 35 does not function purely by substrate destabilization. Removal of the side chain of Cys 35 (Cys→Gly 35) lowers the affinity of the enzyme for tyrosyl adenylate by the full amount expected for the loss of a hydrogen bond⁴, showing that it makes favourable interactions with the adenosine moiety of the products as well as with the transition state.

It seems unlikely from model building that the mutation of residues in this study will cause any structural artefact. Further, the double-mutant test has been applied to residues 35 and 48 and no change of structure was detected⁶.

We have concluded, therefore, that the interactions of important side chains of the enzyme with tyrosine remain unaltered but that those with ATP are optimized as the enzyme-substrate complex reaches the transition state. Thus we have shown that the binding energy of the enzyme and substrate can be used to enhance the catalytic rate and we have quantified its importance.

This work was supported by the MRC.

Aromaticity of soil fulvic acid

FARMER and Pisaniello¹ claim that: (1) aliphatic and aromatic oxidation products of the podzol Bh fulvic acid, especially after premethylation with diazomethane, are mainly artefacts or contaminants; and (2) the formation of these oxidation products cannot be reconciled with the ¹³C-NMR spectrum of the fulvic acid.

I have the following comments: (1) Benzenecarboxylic, phenolic and aliphatic carboxylic acids are not only the major oxidation products of the alkaline KMnO₄ oxidation of unmethylated and methylated fulvic acid², but also result from the oxidation of unmethylated fulvic acid with alkaline CuO (ref. 3) and alkaline H₂O₂ (ref. 4) as well as HNO₃ (ref. 5) and CH₃CO₂OH (ref. 6). Thus, diazomethane has nothing to do with the types of products resulting from the oxidation of the fulvic acid.

(2) Both solid-state⁷ and liquid-state (refs 8, 9) ¹³C-NMR spectra of fulvic acid show signals near 20 and 30 p.p.m., indicative of the presence of terminal CH₃ and (CH₂)_n in alkyl chains. Other resonances are detected between 50 and 85 p.p.m., arising from amino acids and carbohydrates. Major signals near 130 p.p.m. indicate the presence of aromatic carbons not substituted by O or N. But in the liquid-state ¹³C-NMR spectrum of the methylated fulvic acid⁸, now soluble in CDCl₃, the broad band near 130 p.p.m. is resolved into four sharp signals, clearly indicating improved resolution. The comments of Farmer and Pisaniello on this point are irrelevant because they erroneously assumed that this spectrum was run in base instead of CDCl₃. Other strong signals in the ¹³C-NMR spectrum of fulvic acid appear near 180 p.p.m., due to carbon in CO₂H groups. While some humic substances show signals between 150 and 160 p.p.m., others do not. It is possible that because of substitution effects, the chemical shift due to phenolic carbon is moved downfield so that signals arising from phenolic carbon and carbon of CO₂H groups overlap. It is noteworthy that after methylation of the fulvic acid, the presence of phenolic carbon is indicated by a sharp signal at 56.3 p.p.m. Thus, contrary to the claims of Farmer and Pisaniello¹, the structural information on fulvic acid provided by ¹³C-NMR agrees with that indicated by chemical degradation.

Dialkyl phthalates are the only plasticizers that have so far been detected in oxidation products of fulvic acid². The oxidation of dialkyl phthalates would be expected to yield benzenedicarboxylic acids. But how can dialkyl phthalates be oxidized to benzenetri-, tetra-, penta- and hexacarboxylic acids and phenolic acids?

Therefore, it is highly unlikely that significant amounts of oxidation products arise from contaminants. Another important indicator of aromatic fulvic acid components is the relatively high content of free radicals⁴ that have the spectroscopic characteristics of semi-quinones. I conclude from the above that aromatic structures are significant constituents of fulvic acid. The question of whether or to what extent hydroxyl-substituted unsaturated aliphatic carboxylic acids are present in fulvic acid, awaits the isolation of significant amounts of such structures, which, so far, nobody has been able to do.

FARMER REPLIES—Preston and Schnitzer¹ suggested that the four sharp aromatic carbon signals that they observed in the ¹³C-NMR spectrum of methylated fulvic acid might arise from benzene polycarboxylic esters, and supposed that the parent acids would not be detectable in ¹³C-NMR spectra of fulvic acid dissolved in alkali. We found² that such acids were readily detectable as sharp signals when added to an NaOD solution of fulvic acid: our comments are therefore entirely relevant, as they negate Preston and Schnitzer's hypothesis¹, and establish, conclusively, that simple benzene polycarboxylic acids are not even a minor component of fulvic acid. The four sharp signals observed in the methylated fulvic acid can arise from little more than four different types of benzenoid carbon. They are therefore unlikely to be associated with benzenoid carbons of the diverse types indicated by the multiple aromatic degradation products of fulvic acid, reported by Schnitzer and co-workers. The four bands are more likely to arise from a contaminant.

The references cited above by Schnitzer illustrate that reports of high yields of benzene and hydroxybenzene polycarboxylic acids in the oxidation products of humic and fulvic acids originate almost entirely from his laboratories. Consider-

ing, for example, only the non-phenolic benzene polycarboxylic acids, Schnitzer and co-workers have reported yields mostly in the range 6-14% of the starting materials. In contrast, Ogner³ and Spitteler⁴ obtained yields of only 0.12-0.38% of these acids. In a careful quantitative study using permanganate oxidation, H. A. Anderson of this institute (personal communication) has obtained a yield of 1.63% from a podzol Bh fulvic acid (Contech), similar to the Armadale preparation intensively studied by Schnitzer and co-workers. This yield does not greatly exceed that given by polymaleic acid in the same conditions (0.8%).

Following the suggestion² that ¹³C-NMR spectra could be used to estimate the amounts of benzene and hydroxybenzene polycarboxylic acids in the unfractionated oxidation products of fulvic acids, we have applied this technique to the products of peracetic acid oxidation. The results showed clearly that benzene polycarboxylic acids cannot be present in the amounts reported by Schnitzer and Skinner⁵.

In the absence of confirmation from other laboratories, the high yields of aromatic degradation products reported by Schnitzer and co-workers can carry no weight. We can only speculate on the reasons for these anomalously high yields.

Prostak features a 'unique' integrity-testing facility.

• Prostak cell harvesting systems, new from Millipore's Systems Division, are aimed at particularly difficult cell separations, such as mammalian cell isolation, and cellular material that is produced in a complex, viscous broth. Prostak systems offer simplicity and yield advantages over traditional separation techniques, such as rotary drum filtration and centrifugation. And it offers performance advantages over traditional membrane separation devices, including validatability and steamability. The Prostak line includes both microporous membrane and ultrafiltration membrane devices. The devices are incorporated into pilot-plant and production systems that include all necessary pumps, tanks and instrumentation. The basic Prostak device is completely self-contained, and has no O-rings or gaskets that leak hazardous biologicals. The open channel design of the device eliminates plugging and maintains maximum cell viability. Each Prostak device can be in-

• The Epsilon IgE enzyme immunoassay from Beckman Instruments, Inc. with one-step antibody incubation reduces hands-on time for fast turn-around. The test technology provides outstanding specificity, sensitivity and precision of IgE measurements in human serum. The simplified Epsilon IgE assay uses established EIA methodology with a time-saving easy-to-learn protocol. Tubes are set up once for a single antibody incubation step and washed once. No sample preparation or dilution is needed and 30 + 30 minute incubations allow fast reporting of results. A multi-site sandwich methodology is used. A monoclonal antibody on the bead picks up IgE providing specificity. A polyclonal antibody conjugate attaches to multiple sites on the IgE molecule for greater speed and accuracy. The Epsilon assay has a dynamic range of 10 to 400 IU ml^{-1} , excellent correlation with RIA proc-

How to avoid the 19 critical mistakes in buying fermentation equipment

Make one mistake and you can have problems that include inadequate process control, permanent operator inconvenience and costly downtime.

Now NBS has published a comprehensive review of the problems and pitfalls that await the unwary buyer of industrial fermentors — and some very practical suggestions to help avoid them.

Called *19 Critical Mistakes Made in Buying Fermentation Equipment and What You Can Do to Avoid Them*, this practical guide is available without charge.

• Newly introduced manometric modules for HPLC and LC give a pulse-free flow and a digital pressure readout. The pressure reading is transmitted directly to a recorder or to a computer. These modules from Gilson Medical Electronics, offer continuously variable high and low pressure limit adjustments. They stack onto and draw their power from the Gilson 302 or 303 pumps. Three different models are available: the 802C is designed to complement Gilson pump operations at high pressure and analytical flow rates, the 803C is for use in preparative HPLC systems, and the 804C is ideal for preparative LC. Also new from Gilson is a range of fixed-volume pipettes, Microman MF. Especially designed for the clinical chemist, Microman MF simplifies routine laboratory work. Based on the principle of positive displacement, Microman MF is well adapted to high or low density liquids or viscous samples. Typical applications include serum, whole blood and solvents. Eight different models cover the range of 5 to 200 μ l.

Reader Service No. 110.

A new research kit from Amersham to assess the status of vitamin D.

• Vitamin D status can be assessed simply and accurately using a new research kit from Amersham. The kit measures 25-hydroxy-vitamin D, which makes up 80-90% of total vitamin D metabolites in serum. The assay system uses a competitive protein binding assay and a tritium tracer. Sep-pak cartridges are provided for simple and effective sample purification. The assay range is 2-32ng ml⁻¹ and each pack contains sufficient material for the construction of one standard curve and the assay of 20 unknowns in duplicate. Combined measurements of both vitamin D₂ and D₃ series metabolites are made. The use of Sep-Pak gets round the problem of inaccuracy and unreliability inherent in methods based on solvent extraction alone, while avoiding HPLC or lengthy chromatographic steps. The cartridges can be used with ordinary laboratory syringes if required. Amersham already produces an assay for 1 α -25-dihydroxy vitamin D.

Reader Service No. 111.

The range of Microman pipettes from Gilson.

ADVERTISEMENTS

LIPOSOMES

REPRODUCIBLE - HOMOGENEOUS -
EXTREMELY RAPID

Our new commercial LIPOSOMAT guarantees rapid (5ml within 60 minutes) preparation of uniformly sized

- UNILAMELLAR OR
- OLIGOLAMELLAR OR EVEN
- MULTILAMELLAR LIPOSOMES

depending on the used experimental conditions. Liposome size is selectable between 25 and ca. 600 nm diameter up to 1000 nm for multilamellar liposomes. Sample volume is normally 5-10ml or up to 200ml if used in combination with an additional instrument. High encapsulation efficiency for hydrophilic and/or lipophilic agents. Lipid concentration can be up to 300 mg/ml. Lipid loss during preparation is extremely low: down to 0.1%.

INTERNATIONAL WEEKLY JOURNAL OF SCIENCE

Vol 316 No 6030 22-28 August 1985 £1.80

ANTARCTIC SULPHUR DIOXIDE

Why this new
preparative
method delivers
pure protein
and even
peptide hormones

Well to begin with, you won't compromise high sample load with poor resolution. In fact, our way gives you 10 times greater load and also 10 times better resolution – at the same time!

Sounds too good? Just try advanced electrofocusing by using Immobiline. It's the only system available that lets you immobilize the pH gradient within the gel, puts an end to drift, cuts out conductivity gaps and gives you infinite stability.

Look up J. Biochem. Biophys Methods 8 (1983) 157–172, and find out how preparative electrofocusing separates proteins in quantities of up to 1 gram – completely free from low molecular weight contaminants. Better still, just fill in the coupon and get all the facts. Or try it

straight away, and I'll see that we give you an attractive discount on your first order.

- ☐ Please send me your new brochure on The Immobiline System for analytical and preparative electrofocusing.
- ☐ Please send me your latest catalogue on Quality Chemicals for electrophoresis and electrofocusing.
- ☐ Please call me.

ANNOUNCING A NEW GENERATION OF AUTOMATED PEPTIDE SYNTHESISERS

THE REVOLUTIONARY NEW CHEMISTRY AND DESIGN OF THE CRB
PEPSYNTHESISER II HERALDS A NEW ERA IN PEPTIDE SYNTHESIS.

- ▷ Fast, simple coupling of amino acids with new, stable off-the-shelf 'Pepsyn' Fmoc/active esters requiring no pre-activation.
- ▷ Exceptionally mild reaction conditions, avoiding damaging repetitive acid treatments, lead to higher yields and higher product purity.
- ▷ Avoids the hazardous and frequently destructive final liquid hydrogen fluoride treatment.
- ▷ Unprecedented coupling efficiency results from the combined use of polar polyamide resins (traditionally polystyrene) and a freely permeating polar solvent
- ▷ providing complete compatibility between reaction medium and the growing peptide chain.
- ▷ Continuous monitoring of reaction progress and the option of simultaneous synthesis of two or more peptides is achieved by use of novel kieselguhr supported polyamide resins specifically designed to permit continuous flow of solvent through the reaction medium.
- ▷ Coupling, deprotection and washing automatically performed under computer control using simple programs in everyday language.

PEPSYNTHESISER 2

CRB LEADING THE WAY WITH FMOC POLYAMIDE PEPTIDE SYNTHESIS

Hot on delivery...

...cold on arrival

When you order molecular biologicals from Pharmacia you'll find we're pretty hot on delivery.

We'll dispatch your order as soon as we get it, packing it carefully in wet or dry ice.

Now our enzymes are supplied in screw cap mini vials with new waterproof labels, and will easily fit into your centrifuge

tubes and freezer trays.

At Pharmacia Molecular Biology Division that's all part of the service. We realize that the success of an experiment depends on the quality of the products used and the speed at which you get them. With us you'll find that the only thing kept on ice is your product - not your

experiment.

Contact us today and we'll send you our free catalogue with details of over 800 molecular biologicals.

Pharmacia... your partner in molecular biology.

NATURE VOL. 316 22 AUGUST 1985

iii

COVER

The active volcano, Mount Erebus, on Ross Island in Antarctica. The rate of emission of sulphur dioxide from this volcano has been found to be much greater than previously suspected, with important implications for the Antarctic sulphur budget (see page 710).

When you say "why FPLC" you are half way there...

... because Superose™ from Pharmacia is the peak of evolution in high performance gel filtration for the separation of labile biomolecules.

Over the past 25 years, Pharmacia has developed a broad range of chromatography media, including Sephadex®, Sepharose®, Sephacryl®, MonoBeads™, ProRPC™, and PepRPC™, together with the FPLC System, to meet the ever-growing requirements of experienced, innovative and demanding groups of researchers throughout the world.

Now, the FPLC System and Superose from Pharmacia allow you to use high performance gel filtration without the limitations imposed by silica and stainless steel.

With the introduction of Superose, the Pharmacia range of high performance chromatography media, including MonoBeads, ProRPC and PepRPC has been extended to provide you with gel filtration media for fast, high resolution separations of biomolecules, from small peptides to large proteins and DNA-fragments.

- High performance prepacked glass columns
- Reproducible results
- High recovery of biological activity
- pH stability (1–14)
- Extended column life
- Pharmacia know-how

... so go all the way

Superose pre-packed glass columns with high chemical and pH stability, up to pH 14, provide you with unequalled flexibility in your choice of eluents and greatly simplify your column cleaning routines.

Superose allows you to perform rapid separations (20–60 min) while obtaining high resolution and high recovery, facilitating and improving your work in research, quality control or process development.

Superose has been especially developed for bioscientists and is optimized for high performance separation of proteins, DNA-fragments, peptides and other biomolecules.

SCIENCE IN AUSTRALASIA*

Australia and New Zealand are most alike in their great distance from everywhere else. Both maintain scientific establishments comparable with those of Europe and North America. In Nature's special Australasian issue, Alun Anderson and John Maddox describe their special problems and particular achievements in research and development, and recommend what should be done.

Copies of this special issue are available now.

Australian orders should be sent to:

John Rosenbloom, Macmillan Co. of Australia Pty Ltd., Locked Bag 12, South Melbourne 3205, Victoria, AUSTRALIA. Telephone: (3) 6998922.

Please enclose remittance of A\$6 per copy.

Prices and order address for other countries are set out below

Annual Subscription Prices

UK & Irish Republic		£98
USA & Canada		US\$230
Australia & NZ	Airspeed	£150
Continental Europe	Airspeed	£120
India	Airspeed	£115
Japan	Airspeed	¥85000
Rest of World*	Surface	£120
Rest of World*	Airmail	£180

* (not USA, Canada, Europe & Japan)

GUIDE TO AUTHORS

Authors should be aware of the diversity of Nature's readership and should strive to be as widely understood as possible

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable)

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an italic heading of about 50 words

Letters to Nature are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are

Matters arising are brief comments (up to 500 words) on articles and letters recently published in Nature. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted

Manuscripts may be submitted either to London or Washington. Manuscripts should be typed (double spacing) on one side of the paper only. Four copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963-65). The first and last page numbers of each reference should be cited. Reference to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Requests for permission to reproduce material from Nature should be accompanied by a self-addressed land in the case of

UPDATE IN MOLECULAR BIOLOGY 1985

Genes and Systems in Development

Presented in association with the University of California at San Francisco
OCTOBER 7, 8, 9, 1985 SHERATON-PALACE HOTEL, SAN FRANCISCO

PERHAPS THE MOST IMPORTANT CONFERENCE YOU'LL ATTEND THIS YEAR! Featuring preeminent scientists on the frontiers of uncovering new genetic techniques that will aid in understanding the development of micro- and macro-organisms.

NATURE's conference will keep you abreast of the very latest discoveries in . . .

- the diagnosis and therapy of genetic defects
- oncogenes
- homeotic genes
- yeast development
- the immune system
- the development of neural systems.

CMEs WILL BE AWARDED!

ATTEND OUR GALA CONFERENCE DINNER on Tuesday, October 8, in the historic, glass-domed Garden Court. Admission only \$29.50 per person.

POSTER SESSIONS will be held each day. For consideration, please send working title and brief synopsis to Posters Editor, Nature Publishing Company, 65 Bleecker Street, New York, NY 10012.

MEET SPEAKERS AT ROUNDTABLE DISCUSSIONS HELD EACH AFTERNOON and have ample opportunity to present your own ideas.

ROOM RESERVATIONS: Rooms can be reserved directly with the Sheraton-Palace Hotel by calling 800-325-3535. Please mention your participation in the Nature 1985 Conference to qualify for special rates.

BURSARY PROGRAM for selected graduate students to be announced during August 1985.

YOUR REGISTRATION FEE could be tax

A MAJOR EXHIBITION of scientific products and services will be held in conjunction with the conference.

PROGRAM SCHEDULE*

DAY 1: MONDAY, OCTOBER 7

SYSTEMS

Speakers
F. Bloom
(Research Institute of Scripps Clinic)
J. Gerhart
(U. of California at Berkeley)
C. Nüsslein-Volhard
(Tübingen)
C. Goodman
(Stanford)

Topics
Vertebrate neural systems

Early development—
Xenopus

Early development—
Drosophila
Development of invertebrate neural systems
Caenorhabditis

H.R. Horvitz
(MIT)

DAY 2: TUESDAY, OCTOBER 8

CELLS

Speakers
M. Davis
(Stanford)

Topics
T-cell receptors

U. Storb
(U. of Washington at Seattle)
J.M. Bishop
(U. of California at San Francisco)
M. Ptashne
(Harvard)
I. Herskowitz
(U. of California at San Francisco)

B cells

Oncogenes

Regulatory proteins
Yeast development

E. Jaworski
Monsanto

Plant transformation

DAY 3: WEDNESDAY, OCTOBER 9

GENES

Speakers
R. Palmiter
(U. of Washington at Seattle)
D. Hogness
(Stanford)
W. McGinnis
(Yale)
T. Friedmann
(U. of California at San Diego)
To be announced

Topics
Transgenic mice

Drosophila homeotic gene
Mammalian homeotic gene
Human therapy

*Additional speakers will also appear on the program.

TO REGISTER FOR THE CONFERENCE

Return this form with your check, credit card authorization or an authorized purchase order to Nature Up in Molecular Biology, Nature Publishing Company, 65 Bleecker Street, N.Y., N.Y. 10012.

Please reserve _____ conference registration(s) and _____ seats at the Tuesday Conference Dinner

No more NPT rows, please

The third review conference of the Non-Proliferation Treaty opens next week at Geneva. Old discontents are bound to surface. Can the participants think forward too?

WITH the passage of time, the Non-Proliferation Treaty (NPT) becomes increasingly important. Of all the extant instruments of arms control, it is the only one to include a substantial number (nearly 130) of signatories whose signatures imply self-restraint (as distinct from formal acknowledgement that others are restrained), it is the chief means by which it is possible to distinguish would-be bomb-makers from the rest and it has the virtue of providing a public discussion of nuclear arms control at regular intervals of five years. The third conference in this series, which begins next Tuesday (27 August), is certain to be as wide-ranging as its predecessors. The hope is that it will not be as rowdy as that in 1980, when the conference failed to draft an agreed statement.

The participants seem to have learned a great deal from that fiasco. On this occasion, people seem to have been diligent in their preparation for the review conference. In the hope of providing some kind of structure for the inevitable debate between the non-nuclear powers on the adequacy of the steps taken or attempted towards nuclear disarmament, there is to be a separate committee on the topic. Similarly, the safeguards system and the peaceful use of nuclear power are to be dealt with in an organized way. None of this will prevent complaints or recriminations; but since there is no reason to think that any of the participants wants the NPT to collapse, there are grounds for hoping that vituperation stops short of vilification.

The NPT is often described as a bargain between the nuclear and non-nuclear powers, but it is more than that. The three overt nuclear powers (France and China do not belong) have agreed to search for agreements on the reduction of their nuclear weapons, while the signatory non-nuclear powers have accepted international safeguards as an earnest of their promise not to make them. The treaty also lays down that the nuclear powers will provide technical assistance with the development of civil nuclear power in non-nuclear countries, or at least offer access to the International Atomic Energy Agency (IAEA). Parties of both kinds promise self-restraint, which is where the bargain rests. But both kinds of parties also have what must be supposed to be an identical interest that the number of nuclear powers should not increase. Only that common interest will enable them to hang together in a year when the two principal nuclear powers have nothing substantial to report except that they have reconvened, perhaps in a more hopeful environment, a series of negotiations broken off halfway through the interval since the 1980 conference.

Even so, the non-nuclear powers had better bite their tongues when complaining at Geneva that the nuclear powers should have done more. There are some minuses but also, surprisingly, some pluses. The minuses are that the full extent of the Soviet deployment of SS20 missiles has become apparent, that the countervailing modernization of NATO forces in Western

Europe has begun and that the United States has created at least confusion, perhaps justifiable alarm. Certainly there will be voices raised at Geneva during the next four weeks about the folly of this proposal, of which the best that can be said is that it cannot be as effective as it claims; and many of them will be Soviet voices. The pluses are more easily overlooked. Many governments will have forgotten that in 1980, the Carter administration in the United States had signed the second part of the SALT agreement on strategic weapons, but had not taken it to Congress for ratification, perhaps because it dared not risk defeat, perhaps because of the reason given that Soviet dealings with Afghanistan were an offence. Relations between the two superpowers may not be all they should be, but they have improved a great deal since 1980.

On the issue of civil nuclear power in non-nuclear weapons states, the climate has also improved or has become more realistic. The non-nuclear powers have put behind them the disappointments (for some) of the UN conference on science and technology for development, have put such resources as they have been able to spare for energy production into energy conservation (which always had first claim), but have begun to find opportunities for the economic use of nuclear power; the signs are that the international supply system, stripped of the over-optimism of earlier decades, is working well. Even the safeguards system, much resented by non-signatories such as India, is working more smoothly and less obtrusively — but there is still a need that the details gathered by IAEA inspectors should be made public.

So why are people still worried about the proliferation of nuclear weapons? NPT is an important part of the system for preventing proliferation, but is only a part of it. And during the past five years, there has been literally no progress in persuading those outside NPT to join with the other signatories. Israel remains putatively a nuclear power. Pakistan and India plainly seek the same model. Argentina and Brazil have not ratified the treaty. Nobody can guess what Libya let alone South Africa is about. China and France are conspicuous by standing aside. That is why one of the chief objectives for the next five years should be to persuade backsliders like these to join NPT. The task is political, but the benefits would be great. □

What hope for AIDS?

The temptation to legislate to protect society from the spread of AIDS should be resisted.

HARD cases make bad law, and public anxiety is a poor basis for social legislation. That should be the starting point for any consideration of how government should respond to the demands popping up all over the world that something should be done to protect people from AIDS, otherwise acquired immune deficiency syndrome, now known to be caused by the virus HTLV-III, or LAV in France. That there should be a certain air of panic is understandable. AIDS is a dreadful and also, still, a mysterious disease. Only some 10 per cent of those infected with the virus develop the symptoms that lead almost always to death from adventitious infection, for reasons not yet understood. Little is known, as yet, about the efficacy with which those

Biological manuscripts

Contributors are reminded that, with the transfer of the Biological Sciences Editor to the Washington office, they should in future send **four copies of all manuscripts** offered for publication either (as at present) to London or to Washington.

carrying antibodies against the virus can infect others. Moreover, the death tolls mount. More than 5,000 people have already died in the United States. In Britain (where mortality exceeds 100), other European countries and Australia, while the numbers of those dead are still small, there is the awkward prospect of a rapid increase as the larger numbers of patients with overt disease eventually succumb. It is bound to carry weight with people everywhere that in New York, among males in their thirties, AIDS is reported to have taken precedence over homicide as the chief cause of death. Where will it end, people are asking — and in the meantime they demand protection for themselves from the disease.

That is why it is important that everybody should understand how little can, at this stage, be offered. AIDS is a tragic disease, but a collective tragedy. Its emergence is a piece of evolutionary bad luck for all of us. Although still largely confined to male homosexuals, AIDS is certain in due course to spread more widely (see *Nature* 312, 97; 1984). This appears to have been the case in Zaire since 1977, for retrospectively it has been shown that the virus has been widespread and heterosexually transmitted for the best part of a decade (Piot *et al. Lancet* ii, 65; 1984). Already in the United States, there are reports of some scores of infant deaths, presumably as a consequence of congenital infection. There is nothing to suggest that AIDS will not become just another venereal disease, but one not tractable to the antibiotics familiarly now in use. Fortunately there is as yet no evidence that the virus is transmitted by means other than sexual intercourse of one kind or another.

What, in these circumstances, should public policy be? Plainly there is an urgent need that strictly adventitious infections should be avoided. The cases of haemophiliacs infected through contaminated blood are doubly tragic; people disabled by an inherited genetic deficiency are cruelly dealt with if society cannot provide them with a safe palliative. There is the strongest reason why haemophiliacs and others in need of blood transfusions should be protected as far as possible by the use of the screening assays so far developed; there is even a case that those discovered to have HTLV-III antibodies in their blood should be identified, warned of their condition and black-listed as blood donors. So much is feasible and urgently necessary. Governments should not stint themselves. In Britain, the government should not expect hard-pressed health authorities to provide the extra funds they will need out of budgets already trimmed to the bone.

How much further is it possible, or wise, to go? There is a natural temptation to make the disease notifiable in the technical sense, which would give health authorities the power almost automatically to confine patients in isolation; quite apart from the lack of isolation facilities that would be required to keep patients out of contact with other people for months on end, the result would almost certainly be that those most at risk would be deterred from seeking medical help for suspected infection. Sensibly, most governments and the British in particular have resisted this course of action. Others, however, would go even further. Dr John Griffin, director of the Association of British Pharmaceutical Industry is reported by *The Times* to have written urging that there should be compulsory screening of male and female prostitutes, groups almost certain to be or to become foci for the spread of infection. The obvious difficulty is that there can be no effective way of enforcing such legislation. How is prostitution to be defined? What assurance can there be that, given a workable definition, the result will not be that prostitutes are even more firmly put out of touch with physicians? These are problems that those seeking to control the venereal diseases that already exist have grappled with in vain for years. Even though AIDS is a sombre shadow over public health, there can be no reason why these diseases should be more easily conquered now than in the past. In any case, not nearly enough is known about the transmission of AIDS for it to be more than a presumption that prostitution is such a crucial link in the process. Legislation would probably do more harm than good. Public education is the better course.

The message that needs to be made public is unusually depressing. Prophylactic vaccines are a long way off. The prospects for curing people who have developed the disease are even more distant. Palliation is uncertain, as things are. How is it possible to inform the general public about an infectious disease for which so little can be done? There are two cheerful things to say. First, it is a mere four years since AIDS was recognized as such, since when the infecting organism has been identified by heroic efforts in the United States and France; at least diagnostic kits for AIDS antibodies now exist, and will be improved. And, by good fortune, the lymphocytes which are the targets of the virus are also at the centre of one of the most rapidly moving fields of research, from which it is not unreasonable to hope that ways of manipulating the process of infection will spring. But, second, there has also grown up, in this short time, experience of how patients can be helped psychologically to come to terms with their condition, and with the importance of behaving so as to make an individual contribution to the process of trying to slow down the spread of the disease. The public clinics in the United States have mostly shown a remarkable blend of compassion and hard-headedness in their care for patients. The pity is that so many of the communities in which they work are over-zealously concerned to seek personal safety in illiberal legislation. □

Academic independence

The British government's inquiry into the University Grants Committee could be useful.

THE British government's plan (see p. 669) to review the constitutional status of its University Grants Committee (UGC) should not provoke the knee-jerk reaction that comes first to mind. Since 1919 the University Grants Committee has been a buffer between the government and the universities it supports. For most of the time, the committee has been applauded as a unique (and even uniquely British) device for spending public money without running the seemingly inevitable risk of government interference. (The British Broadcasting Corporation enjoyed a similar reputation until its governors caved in three weeks ago to an ill-judged request from the Home Secretary not to broadcast a film on Northern Ireland, and until it leaked out that BBC appointments are regularly vetted by the government's intelligence services.) Certainly, the existence of UGC has ensured that the affairs of individual universities are not open to scrutiny by, for example, the House of Commons, which has suited both the university system and successive governments. Broadly speaking, the committee's recommendations about the development of the individual universities as well as the system as a whole have also been fair and constructive. The fly in the ointment is that UGC's seeming independence has always been more apparent than real. During the six years of the present government, ministers have chosen to remind the universities of the old doctrine about the right of the one who pays the piper to call the tune. The committee's independence has been undermined. There is at least a chance that the inquiry now to be mounted will restore some of that independence.

Constitutionally, UGC is not an executive body but yet another advisory committee. Each year it makes recommendations to the Department of Education and Science about the distribution of the funds available, whereupon the government writes the appropriate cheques. There has never been an occasion when the government has rejected UGC's advice, but constitutionally there is no reason why that should not happen. Over the past decade (since before the present government took office), UGC has lost the essential benefits of the old quinquennial system under which the scale of spending was fixed in outline five years in advance; now there are three-year rolling forecasts, which may be changed from year to year. That was the rubric under which the government arbitrarily announced, at the end of 1980, that the total budget of the universities would have to shrink by 8.5 per cent over three years; the UGC of the time incurred the wrath of those universities whose budgets

were disproportionately made to shrink, which was a convenience for the government which had already decreed what fees should be paid by students from overseas. After all this buffeting, UGC lies in a constitutional limbo made more ambiguous because it has no staff of its own, and no freedom to spend money on the techniques of running an office.

The biggest challenge to UGC's independence lies only a little way ahead. The committee has made no secret of the opinion that the time will soon arrive when it will be prudent for at least one of the universities in the British system to be closed. The overall budget is still shrinking by about 1.5 per cent a year in real terms, while savings that may arise from a more selective distribution of funds will not come soon enough to ease the pressure. Traditionally, in such a circumstance, it would be for the committee to say which institution should be shut, but it has plainly said that it will leave that invidious decision to Sir Keith Joseph, Secretary of State for Education and Science. The reasons are plain. Given that the British government is the ultimate paymaster, there is no chance that a decision to close a particular university could fail to become a political issue. There will be rows in the House of Commons, while the government itself will be tempted to make electoral calculations when deciding which parliamentary constituencies to offend. When that time comes, probably before the new inquiry is complete, it will be generally apparent that UGC is not in charge of the British university system nor even a universal buffer between it and the government. At that stage, the government will also be in a mood to regret that it has so emasculated UGC's independence.

This is an opportunity that British universities should exploit. The government's interest in the past few years has extended beyond budget-trimming to schemes for encouraging more concentration on science and technology and attempts to create a closer interaction between universities and industry, partly for its own sake but also in the hope of saving money. UGC has responded within the limits of its means as positively as could be expected, but the government has found that the provision of more places in science and technology cannot be engineered out of the blue, at no extra cost. Sir Keith Joseph has insisted on his government's right to shape the university system in ways like this, and within the bounds of what is possible, the claim cannot be denied. But the government cannot ask for what is not possible, nor can it, without the advice of people who know the university system intimately, know what it possible and what is not. From these considerations, the Butterworth committee's recipe for change should follow immediately.

First, UGC should be constituted as an independent public corporation, with the resources to manage its own affairs and the freedom to employ its own staff (mostly, at present, on loan from the department, but with increasing help from the universities). Second, it should be made financially autonomous, with the power to write its own cheques in favour of the institutions in its care — and the equally important right to carry over money from one year to the next. (Ideally, UGC should be able to accumulate the kinds of trust funds on behalf of British universities in general which do not at present exist.) But how to take account of government policy on universities? Simply by requiring that the membership of UGC should include the ministers responsible, the Secretary of State for Education and Science or his deputy, perhaps other heavyweights as well. Conventionally, of course, ministers do not belong to committees of which they are not the chairmen, but that would in this case be inappropriate. The record of the past few years shows that ministers have much to learn about higher education as a whole; membership of UGC should be quickly educative. But UGC itself is a sleepy and over-cosy committee, inclined to regard the British government's decisions about budgets and the like as slings and arrows of outrageous fortune. Its meetings would be more lively and more pointed if the perpetrators of these insults, real or imagined, were to be found around the same table once a month. And by what other means can there be a genuine partnership between the British government and the academic community on the management of the university system? □

Justice by bankruptcy

The Manville solution for the settlement of claims by asbestos victims could become a precedent.

THE Manville Corporation of the United States has had an eventful, no doubt salutary and (for the rest of us) admonitory year. Historically, the corporation has been a processor of asbestos and a manufacturer of asbestos products. In the past decade it has found not merely that its business has declined as the use of asbestos in the construction industry and elsewhere has declined, but that its existence as a commercial corporation had been put in jeopardy by the volume of the claims by private individuals and their families alleging that their health had been damaged by asbestos fibres, which are known to be capable of causing a characteristic form of lung cancer. Three years ago, no fewer than 60,000 lawsuits had been laid against the company, which took the unusual but proper step of seeking protection under the US bankruptcy laws. The company now guesses that the total amount of the outstanding claims amounts to more than \$2,500 million, more than it could hope to raise by liquidating its assets. So, if the suits were to have been taken seriously, the company was technically in the position of not being able to meet its creditors' claims out of its own resources, which is the same as to say that it was technically bankrupt. But to have sold up would have been of little help to the claimants, which is why the company sought protection under Chapter XI of the bankruptcy act, which allows a company to continue to run its business under court supervision, in the hope of generating the funds with which to pay off its debts. (Companies and also creditors elsewhere may envy this enlightened legislation.)

The outcome of Manville's flight to the shelter of the bankruptcy laws is nevertheless surprising and, in some ways, ironic. Part of the difficulty in dealing with the lawsuits has from the outset been that nobody could predict how many lawsuits were yet to be laid by people in whom overt signs of damage were not yet apparent. But how can the accountants take account of imponderables like this when trying to decide whether a company is technically bankrupt? The courts have fortunately devised a way, one that is almost certain to be followed in other such circumstances. The principle is that legitimate claimants against the company shall be compensated not by the outcome of the particular lawsuit they may have laid, but by means of payments from a trust fund Manville will be required to set up. First, there is a substantial sum due from Manville's insurers (big enough to have caused trouble on the Lloyds insurance market in London). Manville itself is required to bless the fund with \$200 million in cash and if necessary to hand over 20 per cent of its annual profits. The trust fund is also to own a substantial part of the company and there is a complicated arrangement about convertible preference shares that will, according to the volume of legitimate claims eventually made, allow the fund to finish up owning as much as 80 per cent of the company. The issue will be decided next month.

That, of course, is the irony. Manville and its existing shareholders are being required to do the decent thing in financial terms by its past and future victims, but in a way that gives them an interest in the success of the business. The potential advantages are, however, important. Settlements should be quicker. Less of the funds available for compensation will stick to the lawyers' hands by way of contingency fees. And it will be easier for people who think they may have been damaged to tell where they stand. If the small flurry of lawsuits being brought against tobacco companies on the grounds that cigarettes cause lung cancer should stick, other companies than Manville will be rushing off to the bankruptcy courts. The obvious difficulty is that the feasibility of a tobacco company continuing to trade would depend crucially on an actuarial calculation of whether the cost of compensating victims would suck up all the profits from selling cigarettes to those who escape. The moral, for those who must smoke, is to switch to a brand made by a manufacturer whose business is not solely tobacco-based. □

Radiation exposure

British nuclear workforce assessed for risks

RESULTS of a study carried out by the British Medical Research Council (MRC) claim that there is "no significant risk to health" from radiation to people working for the UK Atomic Energy Authority (AEA). The study, published last week in the *British Medical Journal* (291, 435 and 440, 1985), relates mortality to recorded exposure to ionizing radiation for 39,546 employees of AEA between 1946 and 1979. Of the 3,373 deaths that occurred, 937 were from cancers; overall, death rates of the sample population were lower than those in the country as a whole, but consistent with those expected in a normal workforce and probably accounted for by the social class of AEA employees. But one type of cancer, prostate cancer, was unusually prevalent in the sample group.

The UK study was undertaken as a result of a report in 1977 from the United States, which suggested that the risk of developing cancer after exposure to low-dose ionizing radiation is 20 times greater than the recommendations of the International Commission on Radiological Protection (ICRP). That study, which investigated a workforce in the US nuclear industry, has been criticized for its methodology and analysis of results. AEA therefore asked MRC to commission an independent survey of mortality in its own workforce. MRC's epidemiological study was performed by Professor Geoffrey Rose, Dr Valerie Beral and colleagues at the London School of Hygiene and Tropical Medicine. Mortality of all AEA employees since 1946 was examined and the results compared with ICRP's figures.

The authors of the new study say that their data give no unambiguous guide to the feasibility of estimating the radiation risks to people exposed to low doses by extrapolation from the mortality among the survivors of atomic bomb explosions, exposed to acute doses, the basis of the ICRP recommendations. The correlation between radiation exposure and mortality is so uncertain that, at the 95 per cent confidence limits, the data are consistent with a chronic radiation risk 15 times greater than that suggested by ICRP and, at the other extreme, a risk which decreases with increasing dose.

Of the deaths that occurred, leukaemia rates were slightly above the national average, but as the total number of deaths from this cause was small (35 overall, or 4 per cent of all cancer deaths) the excess could be explained by chance fluctuations. Mortality was not, in general, correlated with radiation exposure, the exception being prostate cancer, which caused 38 deaths. This figure is several times greater

than the national average in the small groups of workers who had relatively high exposure to radiation and who had also been monitored for contamination by radionuclides, particularly tritium. No explanation for this result is suggested by the *British Medical Journal* papers, which point out that tritium is not prostate-seeking, but that tritium contamination may be an indicator of some other agent.

MRC is now "actively considering" how to investigate further the results on prostate cancer. The epidemiological study is being extended for a further five years,

partly to obtain more reliable statistics and partly because, as people in the sample become older, more cancers will emerge which will allow risk estimates to be recalculated with greater precision.

Over the next few years, other UK studies on the effects of radiation will attain the stage that this MRC/AEA survey has reached. Studies in progress are on atomic weapons research staff, staff of British Nuclear Fuels Ltd (preliminary results already published), the National Radiological Protection Board's radiation register for the 1970s and the Central Electricity Generating Board's survey on its workforce. Pooling of these results with the existing and future AEA figures from surveys in other countries will enable more confident limits to be set on radiation safety levels and provide a more accurate estimate of the specific risks involved.

Maxine Clarke

Japanese economy

The future is even brighter

Tokyo

JAPAN's economic prospects will be even brighter in the years ahead. That is the message of the latest white paper from the Economic Planning Agency. And although the document repeats the familiar self-criticism of recent years that Japan lags behind the United States and Europe in fundamental science and the development of original technology, the criticism is only muted.

Indeed, the report predicts an economic future for which most European leaders would sell their souls. The past ten years — in which annual growth has regularly been above 5 per cent, two or three times that recorded in the United Kingdom, and in which Japan has emerged as the world's second greatest economic power — is dismissed as an era of "stagflation". From now on, Japan will enter a new age of inflation-free rapid growth.

Three factors will contribute to this expansion. The first is rapid growth in the telecommunications, electronics and other high-technology industries. In 1984 alone, Japanese corporations invested five thousand million yen (10^{12}) in these areas. Second is the growing service sector and increasing urbanization, with the Japanese population becoming ever more concentrated. And third is the growth of Japan's Pacific neighbours — from California through Australia round to Taiwan, Korea and China — which, it is believed, will make the Pacific basin the centre of world economic activity by the turn of the century, leaving the Atlantic nations to wither in their grey and sunless climes.

Only one small cloud floats in this perfect blue sky. Japan now supports a smaller percentage of old people than European countries. But by the end of the century, with the Japanese now the world's longest lived people, the situation

will have reversed and the nation will be faced by huge pension and medical bills. The report suggests that this may be dealt with by raising from 60 to 65 the age at which citizens can receive government pensions and by restricting the number of doctors. And that in turn has led to stern criticism that economic planning agencies have no business deciding welfare policy.

More money for NIH

Washington

IN the last days before its summer break, the US Congress defied the administration by passing a bill instructing the National Institutes of Health (NIH) to award no less than 6,200 extramural research grants in the current fiscal year, slightly less than Congress originally intended but 1,200 more than the administration's planned figure of 5,000 grants.

Thwarted by Congress's limitless generosity to NIH, the administration had tried to commit some of the 1985 budget for the future years of multi-year grants, a move that was challenged on legal grounds by the US Comptroller General. The supplemental appropriation now passed by Congress (HR2577) does not give NIH any money above the \$938 million they had already been given for research grants, but by specifying the number of grants, it prevented the administration from pursuing the multi-year funding plan (see *Nature* 313, 377; 1985). The legality of the administration's plan has not been resolved.

Researchers should not expect their money too soon, however. By denying his signature, President Reagan could yet exercise a "pocket veto" and kill the bill, as Congress is not in session to oppose him.

Tim Beardsley

US engineering

Backing for long shots

Washington

RESEARCHERS who fail to win a grant from the National Science Foundation's engineering directorate will not in future be able to blame the foundation's excessive caution or lack of vision. The dynamic new assistant secretary for engineering, Nam Suh, has instituted a new grant for proposals that are rejected by the peer review system but which are so exciting that they perhaps ought to be funded just in case. This year, 12 such "high risk/high return" projects have been supported, with grants worth a total of \$1.2 million.

The new grant is administered by a special 7-member Committee on Innovative and Exceptional Research (to distinguish it, presumably, from the rest of the research supported by the foundation). The committee's chairman, William Butcher, explains that the grant was established to counter a fear that peer reviews of research proposals are inherently biased against "way-out ideas". Besides funding risky proposals, the committee can consider "highly innovative truly exceptional proposals" (it has not yet received any of these) and, for the sake of completeness, proposals that do not fall into any of the other categories (so far, they all do).

This year the committee was unable to use all the \$2 million at its disposal, perhaps because the scheme only got under way in March, but next year Suh (himself a former grant holder) is planning to put aside \$3-4 million for off-beat ideas, two per cent of his total budget. Because this is less than allowed tolerances on spending, the scheme has not been formally sanctioned by the directorate's advisory board, although according to Butcher most members know about it and approve. The high risk projects supported this year include a scanning optical microscope with a resolution of 50 micrometres, which could be used to examine living cell membranes, studies of polymerization in supercritical fluids and a proposal to generate "squeezed state light", which one reviewer described as being potentially as important as the discovery of the laser.

Butcher emphasizes that the new grant does not eliminate peer review: all proposals are still put through the normal assessment procedure, but some that get mixed reviews and so are rejected by programme managers are given a second chance by his committee. Only one in three of the proposals considered by the committee were funded this year, but Nam Suh hopes that as the word gets around that his directorate will support off-beat ideas, researchers will be encouraged to be more daring in the sorts of applications they make. **Tim Beardsley**

US gene cloning

Academics barred from P4 lab

Washington

THE National Institute of Allergy and Infectious Diseases (NIAID) is to ban the use by outsiders of its high containment laboratory at the Frederick Cancer Research Facility in Maryland. The laboratory, which was much used in oncogene research in the late 1970s, is one of only a handful of laboratories with P4 rating, the highest level of containment facility, and research being conducted there may have to be reclassified at a lower level of confinement if it is to continue elsewhere.

The Frederick laboratory, although formally run by and for the National Institutes of Health (NIH), has in practice often been used by outside researchers who needed access to secure containment. For the past year, the laboratory has been used successfully by Jack Murphy of Boston University Medical Center to clone fusion genes consisting of a synthetic oligonucleotide coding for human alpha-melanocyte stimulating hormone and portions of the structural gene for diphtheria toxin; the research could eventually lead to a "magic bullet" treatment for melanoma.

Last week Murphy went to the subcommittee on toxin cloning of the NIH Recombinant DNA Advisory Committee (RAC) to ask permission to continue the work at a lower level of containment, and also to seek approval for developing under P4 containment chemotherapeutic agents that would kill T and B cells carrying interleukin-2 receptors. This work, to be done in collaboration with Terry Strom of Beth Israel Hospital in Boston, might allow the creation of specific immune defects to prevent rejection in transplant pa-

tients, because resting and "memory" lymphocytes do not express interleukin-2 receptors.

Myron Levine of the University of Maryland, one of the most liberal members of the toxin subcommittee, said the proposed new work should be done only under P4 containment; other members agreed, noting that the effects of chronic exposure to such agents would be unpredictable and potentially harmful. But the subcommittee was then informed by Malcolm Martin, department chairman of the NIAID molecular biology laboratory, that Murphy could no longer use the Frederick facility because of the institute's decision to restrict access to NIH employees.

Faced with the option of preventing Murphy's work altogether, the subcommittee decided that the transplant rejection work could go ahead under P3 conditions, while the melanoma work could be reclassified as a hybrid between P2 and P3 until more toxicity data are gathered.

Martin explained later that the decision to exclude non-NIH workers had been taken because of competition from intramural research and an imminent refurbishment. There is another P4 laboratory in the NIH division of safety that is still available to outside researchers, although the space available is too small for many purposes. But Martin said that to require containment higher than P2 for Murphy's work "doesn't make any sense" because the host bacterium, the disabled K-12 strain of *Escherichia coli*, has no potential to colonize humans. **Tim Beardsley**

Indian guided missile nearly ready

New Delhi

THE Indian missile programme has reached a crucial stage and an advanced guided missile is expected to be ready as early as next year. Earlier this month, Prime Minister Rajiv Gandhi and Defence Minister P. V. Narasimha Rao saw the missile at the Defence Research and Development Laboratory (DRDL) at Hyderabad. They also watched the simulated flight of the indigenously developed missile and the static testing of its motors. Mr Gandhi later laid the foundation stone for a £75 million research facility at a 1,000-acre site 22 kilometres from Hyderabad where the missiles will be "assembled, tested and checked out". The new facility is scheduled to be fully operational in three years, but it is expected to show results next year.

No details are available about the missile's capability or range or if it can carry a nuclear payload. But the development has been welcomed in India in the light of Pakistan's nuclear ambitions. According

to defence scientists, it will have solid and liquid propellant motors and will be "highly sophisticated". The propellants, inertial guidance and control systems have all been developed indigenously.

The missile programme is directed by Mr Abdul Kalam, director of DRDL and chief designer of India's satellite launch vehicle, the workhorse of the Indian Space Research Organisation (ISRO). Four years ago, Kalam was brought from ISRO to DRDL to develop a surface-to-air missile for the defence system that depended exclusively on missiles imported from the Soviet Union.

DRDO, under the directorship of Dr V.S. Arunachalam, who is a metallurgist, is also working on electronic warfare, early warning systems, radars, submarines and a main battle tank (MBT) for the army. DRDO recently signed an agreement with Italy for collaboration on electronic counter-measure systems.

K.S. Jayaraman

UK research councils

The selling of NERC research

THE smallest source of Natural Environment Research Council (NERC) income casts a disproportionately large shadow. Private sector and overseas government contracts account for only £3–4 million out of a £94 million budget; yet, as NERC chairman Hugh Fish emphasizes, "bolting on some consideration of commercialization" is an important priority for NERC strategic research. These activities give Britain's brightest scientific lights overseas experience, which Mr Fish thinks important, and, more to the point, "it is in the national interest that research should be applied as quickly as possible to earn the country money".

What NERC is selling is expertise in applying research to specific technical problems; in contrast, the marketability of hardware that stands alone is of almost minimal interest. Such a priority points to the developing world as an obvious NERC market, one which many of its institutes

are now exploiting

While some of this work is directly contracted with foreign governments, Mr John Morris, senior executive officer of NERC's marketing group, says that a preferred arrangement is a collaboration with a consultant group. The consultants are then responsible to the government or world-aid source for long-term monitoring, logistics and penalty clauses, leaving NERC only as a subcontractor of technical know-how.

The Institute of Terrestrial Ecology (ITE) is a NERC organization that has been involved in contract work for over 10 years. According to Professor Fred Last, ITE deputy director, ITE's experience with contracting has now given it the freedom to choose contracts that fit into its fundamental science programme. He is concerned, however, that few of these contracts have room for a supplement to support basic research; in real money terms, contracts have not yet made up for the decreases in the basic science budget, leading to a "burning up of the resources" on which contracts are based.

The organizational embodiment of NERC's commitment to marketing its strategic and applied research is its Research Marketing Group, which is divided into two parts. The first, which Mr Morris calls "science push", involves finding the NERC projects with exploitable applied research and then working out possible logistics, such as, for example, offering a commercial client the resources of several NERC institutes rather than a single project. The "demand-pull" side, on the other hand, keeps up with the priorities of world-aid funding agencies. Mr Morris claims that far from endangering NERC objectivity by private funding, NERC actually has an edge by offering companies what they do not want to hear as well as what they do. The research group, says Mr Morris, has not been around long enough to judge its effect in financial terms; but the group has had a clear influence in developing "an enthusiasm for a balanced push into commercialism" among NERC institutes.

Examples of this balanced push include efforts by the Institute of Marine Environmental Research to form a joint company for the assessment and exploitation of marine resources concentrating on low-level toxicity testing, marine surveys and mathematical modelling.

Another is the GLORIA sidescan sonar system for mapping the ocean floor, developed by the Institute of Oceanographic Sciences. In cooperation with the US Geological Survey, IOS has been using GLORIA to map the 200-mile economic exclusive zone off the west coast of the United States, with plans for this year covering the Gulf of Mexico and Puerto

Rico. As with other NERC marketing efforts, GLORIA is portrayed as essentially the selling of expertise.

A year ago, NERC, the largest single contractor for DG XII, the European Commission's directorate responsible for science research and development, set up a Brussels branch of its Research Marketing Group to liaise with the Commission.

Elizabeth Collins

British Association

Scottish meeting

BILLED as a festival of science, the annual meeting of the British Association for the Advancement of Science (BA) will be held on 26–30 August at the University of Strathclyde in Glasgow. Roughly 1,500 members are expected to attend, with day visitors and school parties bringing that number up to nearly 3,000.

Exploitation of research is the meeting's primary theme. Over half the papers offered will touch on this topic, including sessions on opportunities in British engineering, engineering in agriculture and the art of forestry. Applied science is also a year-round concern for the BA, as shown by its science and industry committee and increasing corporate interest in the organization. Corporate membership fees have risen more than fourfold over the past year, from £6,221 in 1983–84 to £25,850 in 1984–85.

Another principal theme of the meeting, waste disposal, will be covered by the BA debate on disposal of radioactive waste as well as papers on energy recovery from refuse incineration, geochemical aspects of acid rain, waste disposal and energy, and pollution in the sea. Those interested in the third theme, population, can attend lectures on the biosocial aspects of Scottish migration, breeding in the sea, urban policy issues, and contraception and the control of fertility.

Three BAYS (BA Young Scientists) lectures will be offered, on all-optical digital circuits and the future optical computer, vision and movement and superficial chemistry. Other activities have also been planned to interest the roughly 500 expected BAYS visitors to the meeting.

Sir George Porter will be elected president of the BA on the last day of the meeting. The BA budget has increased by roughly £34,000 this year, from £289,351 in 1983–84 to £324,330 in 1984–85.

Elizabeth Collins

Correction: New Zealand science

SPENDING on research and development in New Zealand in 1984–85 amounts to \$NZ200 million by government, \$NZ68 million by universities and \$150 million by industry. These figures were given incorrectly in the supplement on Science in Australasia (*Nature* 18 July, p.187). □

US troops and AIDS

Washington

THE US Department of Defense (DOD) will from 1 September require civilian blood banks to disclose the names of active-duty personnel whose blood tests positively for antibodies to the acquired immune deficiency syndrome (AIDS) virus. The blood banks have agreed only reluctantly to comply with the DOD request.

Blood banks such as the American Red Cross plan to inform potential military donors, before their blood is taken, that results of tests may be passed on to military authorities; details of how the policy will be implemented have yet to be settled. But the spectre of military donors refusing *en masse* to give blood as a result has become a source of anxiety for blood banks, some of which obtain a substantial proportion of their blood donations from servicemen.

DOD argues that knowing who has been exposed to the AIDS virus could be important for service readiness; for example, vaccinations given routinely to servicemen could be dangerous to those with immune deficiencies. Homosexual rights advocates, who represent one of the high-risk groups for AIDS, protest that unless kept confidential, information from AIDS antibody tests could be used to stigmatize or discriminate against those who have evidence of antibodies, even though many of these may not be infectious and only a small proportion are likely to develop overt disease. The link between AIDS and intravenous drug abuse might also lead to stigma. But DOD, which is separately considering its own mass screening of military personnel for AIDS antibodies, says that test results will be used only for medical evaluation and counselling.

Tim Beardsley

Japan to Halley

Second comet probe launched

Tokyo

AFTER several days of delay because of bad weather, Japan's main Halley's comet probe (Planet A) finally had a perfect launch from the Uchinoura Space Centre, Kagoshima, on the morning of Monday 19 August.

The satellite was carried aloft by a 28-m tall Mu 3SII solid-fuel rocket at 8.33 a.m. Some eight minutes later, each of the rocket's three stages had separated according to plan and the final "kick" stage had injected the satellite directly into its orbit. Test transmissions were picked up shortly afterwards by National Aeronautics and Space Administration (NASA) tracking stations in California and in Japan, indicating that the launch had been faultless.

The 135 kg satellite, given the name *Suisei* (Comet), will continue into orbit around the Sun. By March next year it will have completed three-quarters of its first revolution and rendezvous with Halley's comet soon after perihelion. Also on hand will be the Japanese satellite *Sakigake* (MST5), launched in January this year and at present orbiting the Sun, waiting for March.

In March, *Suisei* will pass within a million kilometres of Halley's comet and take a series of vacuum ultraviolet (Lyman alpha line) images of the comet's coma as it passes perihelion. This stage of the comet's journey is of particular interest, for water and other volatile materials leave the comet nucleus and are photodissociated through a complex series of intermediate radicals. The UV images should make it possible to identify exactly what stages are involved.

Suisei is rather small compared with the satellites from other nations that will be observing Halley, and everything possible has been done to save weight. The satellite has not been fully stabilized by a three-dimensional attitude control system but will rotate slowly at 5 revolutions per minute. Each time ultraviolet pictures are taken, the satellite will be briefly slowed down by a momentum wheel. A sharp picture will then be ensured by rotating the image on a charge-coupled device to compensate exactly for remaining spin.

Also on board is a pair of sensors for electrons and positive ions intended to observe the interaction of the comet's ionosphere with the solar wind — and particularly to look for turbulence produced by solar flares. Measurements will be coordinated with those from *Sakigake* which will be sitting further "downwind". Although it was launched largely to test the new control and communication subsystems now in use on *Suisei*, it also carried instruments to measure plasma waves and the interplanetary magnetic field.

The launch of *Suisei* is by far the biggest

adventure so far for the Institute of Space and Astronautical Science, the independent academic organization responsible for all Japan's scientific satellites. Preparations have been under way for some

years: a new rocket had to be developed with extra strap-on boosters, a new launch tower built at Uchinoura Space Centre and a new 64-m diameter dish antenna built in Nagano prefecture to pick up the signals. If *Suisei* proves to be a success, a lunar satellite may come next on the list of Japan's ventures into space.

Alun Anderson

University committee review begins

THE promised scrutiny of the British University Grants Committee (UGC) is to be carried out by a committee under the chairmanship of Lord Croom (formerly Sir Douglas Allen), chairman of the British National Oil Corporation; the deputy chairman of the committee is Lord Butterworth, retiring vice-chancellor of the University of Warwick.

The development is important because it is almost certain to lead to a change in the constitution of UGC, founded in 1919 as a buffer between the British government and the publicly supported universities. The need for such a review was most recently advocated by the Jarrett committee on the efficiency of British universities, which reported earlier this year.

The composition of the review commit-

tee is not what British academics would have chosen. Lord Butterworth, made a life peer at the beginning of the year, has been a successful vice-chancellor. The committee also includes Dr Paul Matthews, vice-chancellor of the University of Bath until two years ago, and Mr John Smith, secretary of Imperial College, London. Dr Peter Clarke, chairman of the Scottish Vocational Education Council, was previously principal of Robert Gordon's Institute of Technology at Aberdeen.

The other members of the committee are primarily industrialists, including Sir Alex Alexander, chairman of J. Lyons and Co., Mrs Mark Baker, a director of Thames TV Ltd, Sir Austin Bide, chairman of Glaxo Ltd and Mr Ian Beesley, head of the Prime Minister's Efficiency Unit. □

Soviet science

In the steps of the Ukraine

THE Ukrainian Academy of Sciences, the largest and oldest in the Soviet Union except for the All-Union academy itself, seems rapidly to be becoming a model for the other thirteen republics. During the past few months, the Soviet media have given considerable acclaim to the Ukrainian system of "production centres", semi-pilot factories operating under the academy's aegis. And last month *Pravda* lauded another major Ukrainian innovation — its network of local science centres.

Science centres have been a major feature of Soviet science since the establishment of the Siberian branch of the Soviet Academy of Sciences in 1957. Except for the Ukraine, however, science centres have largely been confined to the Russian republic where, since there is no separate Russian academy, they have come under the All-Union academy.

In spite of official encouragement of science centres as a means of bridging the Soviet Union's endemic gap between research and implementation, the centres have often been criticized for failing to fulfil their allotted tasks. A campaign in the mid-1970s began with the Far Eastern Science Centre and worked its way up to the Siberian branch of the academy before the tide turned.

The Ukrainian network began formally with the establishment, in 1971, of five centres, for the Donetsk, Western, North-Eastern, Dnieper and Southern regions of the Ukraine. By 1980, more than 25 centres

of the whole scientific work-force of the academy was employed in regional centres, spanning marine biology and cryomedicine, high-molecular chemistry and radiophysics. Major developments in the chemical and instrument-building industries have been credited to the centres.

How far the Ukrainian experience could be repeated in other republics, however, is not clear. The Ukrainian SSR is one of the most developed republics of the Union, with large reserves of ores and fossil fuels, as well as much of the best agricultural land. The science centres clearly have had the support of the First Secretary of CPU, V.V. Shcherbytsky, who some years ago publicly urged that Ukrainian scientists should concentrate first and foremost on research needed for the Ukrainian economy. Moreover, the Ukrainian republic is large enough, and has an economy diverse enough, to provide employment for a wide range of scientific talent.

The main problem of the Ukrainian centres as of science in all the non-Russian republics is that of attracting top-flight people. Job prospects in the Soviet Union depend not so much on what, but where, one studies. The brightest students from all republics gravitate towards the top higher education institutions in Moscow and then, almost inevitably, become absorbed into the Moscow-Leningrad-Novosibirsk research network.

WILL BIRD

French nuclear tests

Mystery of *Rainbow Warrior*

LAST month's sinking in New Zealand of *Rainbow Warrior*, flagship of the Greenpeace environmental organization, and the killing of the ship's photographer, have stirred a murky pot of accusation and counter-accusation in France. The French press has taken the scandal to its heart.

One of the more speculative magazines, *VSD*, has even gone so far as to accuse the Elysée palace (the French White House) of having organized the attack to demonstrate French power in the Pacific and determination to continue nuclear weapons testing on Mururoa Atoll; all might have gone well, the theory goes, had not a mole from the British secret service, MI5, buried within its French equivalent, DGSE, tipped off the New Zealand authorities (somewhat too late, it must be assumed). The Elysée will be suing *VSD*,

I was told that Limpet Mines
had no fall-out....

but other speculations implicate KGB, CIA, the home-grown French extreme right and other supposed enemies of equilibrium.

In the more serious French press, a picture is emerging that the two people held and now formally accused in New Zealand are probably members of the French Army seconded to DGSE to survey the activities of Greenpeace. It is suggested that the frogmen who attached two limpet mines to *Rainbow Warrior* left behind their French inflatable dinghy and bubble-free breathing apparatus (stamped "Made in France") and probably escaped in a hired yacht, *Ouvea*, belonged to a separate French group.

The bombers themselves, like *Ouvea*, may have come from New Caledonia, the group of French Pacific islands which is fast becoming President Mitterrand's Algeria — a country peopled by some 91,000 native Kanaks seeking independence and wooed by M. Mitterrand but also 54,000 French colonists who are determined the island shall stay French. These French might have wished to discredit the present government — and hence the trail of evidence left behind, it is suggested.

However, this relatively convenient picture is inconsistent with the fact that

Ouvea was hired (for FF 70,000 cash) through a Paris agency. The hirers were an adventurer French doctor (who specializes in diving medicine, but who left *Ouvea* before the attack and claims he knew nothing of the object of the mission) and three more shadowy figures, since disappeared with the yacht.

The *Rainbow Warrior* crew also believes there was a French "mole" aboard, a woman who sent articles for a "French paper" and one of whose maps of New Zealand waters was later found on *Ouvea* (when the yacht was briefly stopped and then released, to the later chagrin of the New Zealand police). This woman has also disappeared, via, apparently, an archaeological dig in Israel.

President Mitterrand has asked M. Bernard Tricot to carry out an investigation and to inform the public.

But if indeed the French secret service does prove deeply involved, what possible government motive — or perception by junior officials of a government motive — could there have been to bomb *Rainbow Warrior*? The only possibility could be to protect the French nuclear weapons tests on Mururoa, not far from New Caledonia

and Tahiti, which Greenpeace intended to disrupt. The French nuclear arsenal is in continual evolution and even expansion with a postulated introduction of "enhanced radiation weapons" or neutron bombs and a testing campaign of at least another 15 years is planned. Speculation by the French that *Rainbow Warrior* was carrying sophisticated devices for detecting neutron bombs (discounted by Greenpeace, which says the ship carried only a geiger counter and apparatus for relaying pictures to news agencies) suggests that perhaps France was indeed planning a neutron weapon testing programme.

But whatever the merits of this speculation and of an attack on Greenpeace as a counter-measure, the opposition of South Pacific states to French testing, at the rate of 60 weapons between 1977 and 1984, is now liable to increase, since the signing earlier this month by seven nations of a declaration that the South Pacific should be a "nuclear free zone". The treaty, which forbids signatories to build or test nuclear weapons, will be ratified by the end of the year, Australian Prime Minister Bob Hawke has predicted, and though powerless to prevent French testing in the region it will certainly increase French political isolation. The *Rainbow Warrior* affair can only have done the same.

Robert Walgate

French mistrusted on Mururoa

MURUROA Atoll, according to New Zealand and Australian scientists who visited the French nuclear weapons testing site in October 1983, is likely to release its accumulated load of debris from underground explosions to the Pacific "within 500–1,000 years".

At present, they say, emissions from the island and consequent fallout in the South Pacific region are having a negligible effect on health and they do not suggest that even the likely release of the contained radiation within a few centuries will be "consequential". But the scientists' evident suspicion of French calculations about the security of the site is symptomatic of the South Pacific's distaste for what the French are doing with "their" atoll.

For example, "French information on venting is very qualitative", the South Pacific scientists say in their report, "and there is no reason to believe their figure that more than 99 per cent of the radioactivity is retained in vitrified material". And any "implicit impression" that venting is barely detectable is "almost certainly false".

On underground containment, the report indicates that the French tests are "probably" 700–1,200 m below the bottom of the lagoon, in the volcanic base of the atoll, which is surmounted by 180–500 m thickness of limestone. But the limestones contain some highly porous sections and the volcanics are fractured for 400 m

around each explosion. "The volcanics in their virgin state offer a poor to moderate geochemical barrier and a moderate to good hydrological barrier. "The testing programme is reducing the effectiveness of both", the report says. Moreover, "the claim that the transition zone [between the volcanics and the porous limestone] acts as a barrier to long-term leakage can, on the basis of geological evidence, be discounted".

Thus there will be leakage within 500–1,000 years, in which transuranic elements without a particular geochemical affinity (such as neptunium-237) may be expected to be leached out. "It would be surprising if this leakage were consequential", the report says, but such scientific assurances, according to an Australian government spokesman last week, have made very little impression on public opinion. Rational or irrational, the public view is that far more atomic weapons have now been exploded in the South Pacific than in the north (the public thinks of Hiroshima and Nagasaki) and that it is simply high time the bombing stopped.

But France will not stop, which may, in the long run, lead to a search for a new site. A deal with French Africa to use the Sahara (from which the testers decamped to Mururoa in 1966), or a deal with the United States to use its own sites, emerge as the only faint possibilities.

Mt Wilson Observatory

SIR—We have recently returned from what seems all too likely to be our last observing run as guests of the Carnegie Institution with the 100-inch telescope at Mt Wilson, California. We had 14 consecutive nights on the telescope. All of them were clear, the only cloud that we saw during that whole time was a little cirrus, which did not impede us at all, on one night. Star image diameters near one second of arc were the norm, and on several occasions we enjoyed "seeing" much better than that — the remarkable seeing for which Mt Wilson is renowned.

To experience such enviable observing conditions for such a sustained period on our final observing run heightens the irony of Mt Wilson Observatory being closed down ostensibly because of the deficiencies of the site. The 100-inch was shut down finally, as far as its owner the Carnegie Institution is concerned, on 26 June 1985.

Like every one of the major instruments on Mt Wilson, the 100-inch has played a role of extraordinary distinction and significance in the progress of astronomy throughout much of this century. But it should not now be allowed to rest on its laurels. The same telescope that served Hale and Adams, Hubble and Humason, Baade, Sandage and countless others so well in the past is still in the same class as the very best of the newer telescopes, and behind its now-closed shutters it sits ready and waiting to resume the battle with the pressing problems of present-day astronomy. In this connection it is of interest to recall that observers at the 100-inch, casually viewing Saturn, were well aware of the "gramophone-record" appearance of the rings¹ before *Voyager* drew attention to that structure; but an experienced planetary observer who observed Saturn under the best conditions at the 200-inch Palomar telescope specifically asserted² that no subdivisions exist in the rings.

The very short time-scale upon which the announcement (made barely a year ago) of the closure of Mt Wilson is being implemented has made it impossible for any other organization yet to assume financial and operational responsibility for the observatory. Although the 100-inch telescope is the first to close, the 60-inch and the solar telescopes will soon follow it if they too are not taken over by other operators. The formidable researches that are being undertaken with those instruments, all of them long-term projects that would suffer severely from even a temporary interruption, are described with extraordinary honesty in the current annual reports of both the president of the Carnegie Institution and the director of the Mt Wilson & Las Campanas Observatories. The juxtaposition in those reports of the current achievements of Mt Wilson Observatory and the closure of the self-

same place leaves the reader altogether incredulous.

The Athay Committee, which was set up at the request of the director of Mt Wilson to advise on the future of the observatory, rightly refers to the "anguish" of astronomers around the world at the closure of such a distinguished observatory. The committee's report makes a strong case — actually not a difficult thing to do — for the retention of Mt Wilson in operation, and includes a recommendation that Carnegie should at least continue to run the observatory for a reasonable period until an orderly takeover by another operator can be arranged. Unfortunately, the Carnegie Institution has apparently not been able to counter reasoned argument with reasoned argument, but instead has chosen to respond with ever fiercer press releases that appear to constitute its only acknowledgement of the receipt of the report which it requested. Its position seems analogous to that of St Paul on the Damascus road before his conversion³; we devoutly hope that the parallel is completed and/or that some other institution will soon be found or set up to maintain and even enhance this great observatory. Long live Mt Wilson!

Soviet tests

SIR—If your reporter meant to imply in his report on the American Association for the Advancement of Science (AAAS) meeting in Los Angeles¹, that I accused the US government of lying on the question of Soviet compliance with the Yield Threshold Test Ban Treaty (YTTBT), I must take exception. I personally have no way of knowing for certain whether the assertions by some representatives of the US government^{2,4} that the Soviet Union has tested over the treaty threshold of 150 kton are accurate, even less do I have any grounds for implying intent to deceive on the part of those representatives.

What was pointed out at the AAAS meeting is that the techniques for calculating unbiased estimates of the yield of underground nuclear tests have been well understood for over a decade^{5,6}. The most recent published work that I am aware of⁷ concludes that within the resolution of the seismic data and analysis techniques used, the Soviet Union has not significantly exceeded the 150 kton limit. Unlike most questions of Soviet treaty compliance, this work does not depend upon classified data or analysis techniques. If the US Depart-

ment of Defense (DOD) has reason to believe that this work is in error, it has a right and an obligation to demonstrate that in the open literature.

However, recent reports indicate^{4,8} that work within DOD supports the finding that the Soviet Union is complying with the terms of YTTBT. If these reports are correct, DOD should make the information public. Surely no-one can have forgotten the bitter lessons of the past 20 years; in a free democratic society, the bond of trust between the government and the people is also a vital component of national security. Moreover it is unthinkable that responsible people would let false pride over a small technical error contribute to making matters any worse than they already are between the two great nuclear powers.

Prehistoric calendar

SIR—Correspondence has recently revealed a mistake of 1° in the azimuth given for the equinoctial sunset notch at the prehistoric site at Brainport Bay, Argyll (*Nature* 314, 158; 1985). The reduction of six solar observations taken at the Oak Bank stone backsight gave an average azimuth of the notch of 99.46° west of true north and its declination of +0° 8' was calculated from this. Somehow this azimuth became a true bearing of 261° 32.5' in the text and in Fig. 4, whereas it should of course be 260° 32.5'. A fresh reduction of the same observations by a different method gives the same azimuth and a declination of +0° 9.6'.

On 21 March 1985, about 26 hours after the astronomical equinox, the setting Sun was observed from the Oak Bank rock carving until it was about a solar diameter above the horizon, where it was photographed; at that point it disappeared into a bank of cloud but the disk was clearly heading directly into the notch. This of course confirms the calculations and also the inference drawn from them that we have at Brainport Bay a precise and still functioning equinoctial alignment.

The science of sea dumping

SIR—In their letter on the science of sea dumping (*Nature* 11 July, p 100), Alan Reddish and Steve Cousins state that "scientific modelling should clearly specify the model in terms of the underlying theoretical assumptions". We agree, which is why the forthcoming Nuclear Energy Agency (NEA) report on the review of the continued suitability of the north-east Atlantic dump site¹ contains over 60 pages of description of the models developed by the Ministry of Agriculture, Fisheries and Food (MAFF) and the National Radiological Protection Board (NRPB) to assess the radiological impact of sea dumping of radioactive waste on both humans and marine organisms.

Clearly, Professor Holliday and his team² could not include all this detail in their report and there was no need since it is to be published elsewhere. However, the full description was provided to them, to the NEA expert group for the dump site review and to the panel of scientists carrying out the London Dumping Convention review.

Reddish and Cousins also express concern about experimental validation of models, but they fail to realize the difficulties involved and the extent to which field measurements have in any case been used. Direct validation of the whole suite of models is simply not possible because of the large time and space scales involved and the very low radionuclide concentrations. What can be done is to validate those parts of the models that have most effect on predicted radiological impact.

Studies of model sensitivity show clearly that it is the interactions between radionuclides and suspended and seabed sediments that most influence doses. This part of the model has been validated¹, using data on naturally occurring radionuclides in the ocean. Data from the earlier dumping site in the English Channel cannot be used for direct validation because the site is coastal while the models deal with dumping in the deep ocean and because monitoring has failed to detect any radioactivity that can be traced to this site. Irish Sea data are also coastal and so could not be used for direct validation, but they can be, and were, used in fixing some model parameters, particularly the factors by which coastal water organisms concentrate radionuclides.

One method of telling whether the results of a particular modelling approach are robust is to tackle the problem in a conceptually different way. The basic model used to estimate dose to man was first of all to predict the distribution of radionuclides in space and time, using an oceanographic model and then to calculate the expected concentrations of radionuclides in sea foods by the application factors.

The concentration factors anticipate the concentration of radionuclides in surface and mid-water marine organisms, relative to the ambient water, as a result of the accumulation of radionuclides from all sources including the ingestion of food. The values used are, for the most part, derived from direct observations. The sea foods eaten by man are all taken in coastal and surface waters to depths of up to 1,500 m.

No sustained food chains from the deep sea (> 4 km) to man are known but, as a safety measure, calculations were also made of the dose to man that could arise if fish living at the dump site itself, close to the bottom, were directly consumed by man. All these calculations indicate very low expected dose rates to man at daily consumption rates of considerable quantities of sea food.

The conceptually-different approach used in the sensitivity analysis was to estimate the dose to man that might arise if, by some chance, contaminated organisms within the dump site were consumed by organisms from outside the area, resulting in radionuclides eventually being transferred to man at concentrations that would not be predictable from the ambient water concentrations, and over a much shorter time scale.

The results of making a number of calculations, based on various ideas as to how such a transfer of radionuclides could in theory be effected, led to the conclusion that even if such occurrences do take place, the resulting dose to man would still be exceedingly low.

There is often a common misconception as to what, exactly, models are attempting to achieve. In this case it is an attempt to estimate the dose to man, and the impact on the deep-sea fauna, as a consequence of disposing packaged radioactive waste into the deep sea. The models used do not aim to represent in detail all known geochemical, oceanographic and biological processes. What they do attempt is a distillation of the major processes and parameters that would be primarily concerned in estimating the dose to man and, by the application of sensitivity analyses model-to-model comparisons, and a verification of major parameters by environmental observation, produce sufficient information for decisions to be made.

Pain and animals

SIR—R. Sharpe's letter (*Nature* 25 July, p. 290) contains a sentence beginning "Since it is impossible to devise a method of measuring pain in animals it follows that...". If this premise was true, it would indeed follow that regulations against cruelty to animals would depend on doubtful subjective judgements. The problem is not how to assess an animal grossly disturbed by some acute injury which no humane human would allow to continue. Veterinarians and scientists are faced with the much more difficult problem of judging animals with a chronic disorder such as arthritis.

A number of groups have proposed solutions and in particular the International Association for the Study of Pain has published its obligatory guidelines (*Pain* 16, 109–110; 1983). They require a two-stage investigation. First the animal in question is compared with normal animals by measuring quantitatively its behaviour such as movement, grooming, sleep etc. and by measuring its physiology such as EEG, hormone levels, autonomic state and so on. The animal is then treated with a relevant analgesic procedure and its behaviour and physiology are again measured. The first measure describes the abnormality of the animal in objective terms and the second measures the degree of abnormality attributable to pain. It is as crucial for animals as for babies that we should use every available skill to measure their pain in spite of the fact that we cannot speak to them.

Improving crops

SIR—Close to this town lives a tribe of Indians who practise a clearly defined method for improving their crops, particularly maize. Every family plants its own seed, avoiding contamination with alien germplasm. When they find an outstanding example, they do not use it for food or seed; they give it as a present to a friend, who is not supposed to eat it or use it in any other way, but to plant it. The whole action is treated as a religious ceremony or social convention, presumably part of a system ensuring the tribe's continuity. The exchange involves a large part of the community, and is made in all directions.

The obvious objective is to increase the frequency of favourable genes with additive actions, by selecting within a mildly inbred population, in which new forms with desirable characteristics are introduced periodically.

Selenium not for dumping

California is up in arms because of selenium in some drinking water. Does it not know that selenium is also an essential dietary supplement?

WHY do so many land animals depend so crucially on inorganic substances predominantly present only in sea water, selenium for example? The question has most recently been provoked by the fuss, in California, about the discovery last year of selenium in the water stored in the Kesterson reservoir. Officials of the city of Monterey have since refused to allow that supposedly toxic fluid to be allowed to return to the Pacific Ocean. In their ignorance, they have overlooked a question that is not merely of practical importance (how do we keep our people healthy?) but one that has profound significance for people everywhere — where did we come from?

This is how the tale goes. Life began in the oceans or shallow seas. The primitive enzyme systems depended on inorganic ions: (Physiologists have often remarked on the resemblance between body fluids and sea water.) But some of these vital inorganic substances are needed in only small amounts. These are the nutritionally essential trace minerals, such as iodine, molybdenum, manganese and zinc. When living organisms emerged from the oceans, animals and plants that became land-dwellers had to find soil that supplied these minerals. Iodine is uncommon except near the oceans: Plants do not need it, but goitre became an endemic disease of animals in inland areas lacking iodine.

Geological variations in the Earth's crust, glaciation during the great Ice Age, the effects of vulcanism and the results of erosion and leaching are some of the factors that decide which parts of the Earth's surface are either deficient or oversupplied with trace minerals.

In some parts of the world, most conspicuously in Australia, the soil is so deficient in certain trace minerals such as zinc and copper that plants will not grow. Elsewhere, soil contains a toxic excess of some minerals. One of these is selenium, which was known for many years only as being poisonous, even carcinogenic. It came into prominence because certain plants such as *Astragalus* (locoweed) concentrate it from high-selenium soils so that horses that eat *Astragalus* may become poisoned, or "locoed" ("blind staggers"). In the 1930s, Franke and his co-workers reported effects of "toxic wheat" grown in South Dakota on high-selenium soil.

Thomas H. Jukes is in the Department of Biophysics and Medical Physics at the University of California, Berkeley, California 94720, USA.

Feeding toxic wheat or selenium to hens produced deformed embryos in their eggs with eyes and beaks missing, and with distorted wings and feet¹. No such injuries were detected in human beings; the only bad effects noted were dental caries.

The bad reputation of selenium was abruptly changed in 1957, when it was found in laboratory studies to be a nutritionally essential trace element for rats, chickens and pigs^{2,4}. This news was followed with startling rapidity by reports of selenium deficiency in farm animals all over the world, especially in New Zealand. Selenium provided one of the most dramatic illustrations of the rule of Paracelsus that "the dose alone determines the poison", a rule that seems to have been forgotten by most of us.

Among the many studies of the toxicity of selenium were some carried out by the US Food and Drug Administration (FDA) which led to the conclusion that high levels of selenium are carcinogenic⁵. Since official thinking does not permit the extension of Paracelsus' rule to carcinogens, FDA agonized for 15 years before it allowed selenium to be added to the diet of farm animals.

Ironically, selenium had meanwhile emerged as an anticarcinogen and as a component of an important enzyme, glutathione peroxidase, an enzyme important in the metabolism of injurious hydroperoxides⁶.

Now move to China, where multiple myocarditis, "Keshan disease", is found in children in populations with low levels of blood selenium living in low-selenium areas. Epidemiological studies show an inverse correlation between blood selenium and age-adjusted total cancer death rates and liver cancer incidence. In areas with high selenium levels, there is significantly lower mortality from cancer of the oesophagus and stomach. As a public health measure, a programme has been started of spraying grain crops with sodium selenite solution⁷. The difficulty may be that both the population and the food supply may be less mobile than in the United States.

In California (where anything can happen, and usually does), selenium leaching from the coastal foothills of central California (perhaps a result of acid rain) got into irrigation water and became concentrated in drainage reservoirs. Aquatic birds, coots and wild duck, living in the Kesterson reservoir, re-enacted in

1984 the 1930 drama of the South Dakota chickens, producing deformed offspring. Environmentalists sprang into action, saying that selenium would probably cause deformed human embryos. The headlines flared. Officials in Monterey acted. A former head of California Water Resources Control Board spoke of the "Kesterson nightmare", and predicted⁸ "another year's crop of what may very well be contaminated produce".

In reality, the "contaminated produce" is probably helping to protect consumers against cancer^{9,10}. The permissible level of selenium in drinking water, set by the Environmental Protection Agency (EPA) at 10 parts per thousand million, should probably be raised to 50 to 100 parts per thousand million as a public health measure.

Until FDA gave approval for selenium as an animal feed additive, farmers literally had to return to the ocean, the original source of selenium for animals, to obtain selenium for their livestock. This was done by feeding fishmeal, the selenium in which was natural and therefore legal. Selenium has another role in ocean fish; it prevents the injurious action of mercury that is naturally present in seawater and is added to the ocean by volcanic discharge and run-off from coastal soils.

Various hearings on the disposition of the Kesterson water have brought forth recommendations ranging from stopping agriculture in the vicinity of Kesterson to skimming off the surface soil and burying it. In none of the hearings has the essential nature of selenium, or the fact that selenium is a natural resource that tends to be depleted and lost, been discussed or even mentioned. Nor have tolerable levels of intake been suggested. The objective seems to be to treat selenium as a toxicant that must be sequestered, yet much of the land in California and more in Oregon, is deficient in selenium. Shall we have to go back to the sea?

Sodium pump

Birthday present for digitalis

from D.G. Allen, D.A. Eisner and S.C. Wray

EXACTLY two hundred years ago, William Withering published his monograph on the therapeutic use of the foxglove *Digitalis purpurea* in congestive heart failure, then known as dropsy¹. Digitalis is known to bind to the (Na⁺ + K⁺) ATPase, the enzyme that acts as the Na⁺/K⁺ pump in the membrane of cells, and in consequence inhibits the extrusion of Na⁺ and the inward movement of K⁺ ions². The publication, elsewhere in this issue, of the amino-acid sequence of the α -subunit of the (Na⁺ + K⁺) ATPase^{3,4} makes a fitting celebration of the bicentenary. But knowing more about the structure of the Na⁺/K⁺ pump and the way in which cardiac glycosides may affect it should not be allowed to obscure the uncomfortable fact that inhibition of Na⁺ and K⁺ movements may not be the sole or even the most important therapeutic action of the cardiac glycosides.

Although cardiac glycosides, such as digitalis and ouabain, are now among the most commonly used cardiac drugs, many aspects of their mechanism of action and their clinical use are still controversial. Three questions of pharmacological interest are currently claiming attention: how the cardiac glycosides increase the force of heart-muscle contraction (positive inotropy); whether there are naturally occurring cardiac glycosides in human plasma; and whether the cardiac glycosides are equally valuable in all types of heart failure. Recent work has suggested that these issues may be related and may lead to a better understanding of the way in which digitalis works.

The conventional view of the positive inotropic mechanism is shown in the figure (refs 5,6). Briefly, digitalis inhibits the Na⁺/K⁺ pump, leading to an elevation in the intracellular Na⁺ concentration, which acts on a membrane Na⁺/Ca²⁺ exchange to increase the intracellular calcium concentration; this increases the Ca²⁺ content of the sarcoplasmic reticulum and leads to release of Ca²⁺ during systole. There is good experimental support for the increase in the intracellular Ca²⁺ concentration, which represents the final stage of this process⁷. Support for this scheme comes from the fact that other manipulations that inhibit the Na⁺/K⁺ pump also increase the force of contraction. Under these conditions, there is a close relationship between internal Na⁺ concentration and force⁸. This hypothesis has, however, been criticized on two grounds⁹. First the plasma concentration of cardiac glycosides in patients is about 10 nM whereas Na⁺/K⁺ pump inhibition, at least *in vitro*, is only seen at a concentration of about 100 nM (ref. 10). Second, low

concentrations of cardiac glycosides have been reported to stimulate rather than inhibit the Na⁺/K⁺ pump in various isolated preparations, as shown by measuring either ATPase activity¹⁰ or internal Na⁺ concentration¹¹.

Interpretation is complicated because it has been suggested that the apparent pump stimulation is secondary to release of catecholamines from nerve endings¹². This criticism cannot, however, be levelled against the demonstration that the isolated ATPase is stimulated by cardiac glycosides¹³. These experiments have also shown that there is a maintained increase of activity that is not further increased by low doses of glycosides if the ATPase is first washed with a salt solution. This suggests that the stimulation might result from displacement of an endogenous

actually inhibiting the Na⁺/K⁺ pump. The major unresolved question of the 'non-inhibition' hypotheses is how glycoside binding can increase force. Possibly binding may interfere with Ca²⁺ bound to the surface membrane¹⁵. Another intriguing experimental finding is that intracellular injection of low concentrations of glycosides can lead to an inotropic effect that is independent of binding to the extracellular Na⁺ pump site¹⁶. Despite these problems with the Na⁺/K⁺ inhibition hypothesis, however, no clear alternative has yet been proposed.

There is much interest in the possibility that the cardiac glycoside receptor on the Na⁺/K⁺ pump was 'designed' to bind an endogenous glycoside-like substance present in human plasma. As Na⁺/K⁺ pumps are found in a wide variety of tissues, such an endogenous substance would cause, amongst other effects, increase in cardiac contractility, constriction of blood vessels and an increase in Na⁺ excretion by the kidney. Endogenous Na⁺/K⁺ pump inhibitors have been found in toad skin¹⁷ and rat hypothalamus¹⁸, and a substance that inhibits the Na⁺/K⁺ pump has recently been isolated from the blood of hypertensive patients¹⁹. This is particularly interesting because it may be a cause of essential hypertension. Release of this substance in response to a plasma Na⁺ load could increase Na⁺ excretion by the kidney; possibly it is the elusive natriuretic hormone²⁰. This substance should, however, also inhibit the Na⁺/K⁺ pump in vascular smooth muscle, so producing vasoconstriction and consequent increase in blood pressure.

Information about the structure of the Na⁺/K⁺ pump may help us to understand how it is affected by glycoside binding. The sequence data allow us to identify the parts of the molecule that lie within the membrane and those that protrude into the extracellular and intracellular spaces. The ATP binding site and the phosphorylation site are also revealed, and preliminary suggestions can be made about the position of the glycoside binding site. It is particularly instructive in this regard to compare the (Na⁺ + K⁺) ATPase sequence with that of the Ca²⁺-ATPase, also published in this issue²¹. Ca²⁺-ATPase does not bind glycosides and the molecule lacks the sequence that Schull *et al.*³ suggest is the ouabain binding site on the (Na⁺ + K⁺) ATPase.

One of the first questions is how glycoside binding leads to inhibition of the ATPase and to the movement of ions, but more detailed knowledge of the binding site and possible interactions with other regions of the molecule may suggest further consequences of glycoside binding that could underlie the therapeutic effects. For example, glycoside binding might lead to a conformational change in the molecule, thus affecting Ca²⁺-binding in the surrounding membrane.

The amino-acid sequences and structural information so far published show

inhibitor (see below). One problem with this hypothesis is that simply displacing one inhibitor by another at the same site should not result in a stimulation of the pump.

In this context, it is interesting that recent measurements of ouabain binding to membranes have shown two classes of binding sites^{11,14}. The lower affinity one may be the conventional site at which the Na⁺/K⁺ pump is inhibited, whereas the high affinity one might provide an alternative positive inotropic mechanism without

that the Na^+/K^+ pumps from the electroplax organ of *Torpedo californica*⁴ and the kidney of sheep⁵ are strikingly similar. Both α -subunits have 1021 or 1022 amino acids, about 87% of which are homologous, and there are runs of 128 and 108 amino acids that are identical. Six regions of 22–29 hydrophobic residues are probably big enough to span the membrane and the intracellular regions of the molecule can be identified from the locations of the ATP binding site and the phosphorylated site. It is assumed that the glycoside binding site(s) lie on one of the three regions that protrude into the extracellular space. Assuming the glycoside binding site can be unequivocally identified in future, it will be of considerable interest to see to what extent the glycoside binding sites are conserved in pumps from different tissues and species and, in particular, to compare species that have very different sensitivities to cardiac glycosides. Homologies between this and other ion-pumping ATPases^{1,2,21} are substantially lower but offer the intriguing possibility of identifying the crucial amino-acid sequences for common functions, such as ATP binding and energy transduction.

At present cardiac glycosides are used clinically to increase cardiac output in two major conditions. In atrial fibrillation, where the increase in heart rate renders the heart inefficient as a pump, the glycosides, through their action on the vagus nerve, slow the heart and so increase its output. They are also used to treat heart failure, where the rate is normal, but the efficacy of digitalis under these conditions is controversial: Although digitalis treatment can produce a small, short-term benefit²², controlled trials have found little evidence of benefit from maintained digitalis therapy. This may, of course, simply mean that the initial treatment allowed

the heart to recover. Alternatively, prolonged exposure to glycosides could result in the synthesis of more Na^+/K^+ pumps²³, so compensating for those inhibited by the glycosides. If there is an endogenous glycoside-like substance that competes with the therapeutic glycosides for the inhibitory site on the sodium pump, it will be necessary to monitor its concentration during treatment before we will understand the therapeutic role of glycosides.

Whereas, in isolated preparations, large doses of glycosides lead to a substantial inotropic effect that can be accounted for by the mechanism shown in the figure, at the low doses used therapeutically the inotropic effect is much less marked. Even so, it leads to a small but worthwhile clinical improvement. The magnitude of this low dose effect may well depend on the presence of endogenous factors that compete for the same binding site. □

Astrochemistry

Chemistry in dynamically evolving interstellar clouds

from David A. Williams

RECENT observations of interstellar molecular clouds have shown that they have a great diversity in density, temperature and chemical state. The study of these clouds has become important in astronomy because it is generally believed that they are the progenitors of stars. In an important theoretical contribution, Tarafdar *et al.*¹ have described a framework within which the diversity of the clouds may be understood. They suggest that the observed variety of conditions and molecular state is a natural outcome of the evolution of the clouds, as they contract under gravity from low density atomic gas to high density molecular material.

Chemistry in interstellar clouds is now a well established subject² and the mathematical modelling of extensive reaction networks has been investigated by many authors during the last fifteen years. These studies have shown that whereas low density clouds are generally in a chemical steady state, time for denser clouds to approach a steady state — typically 30 million years (ref. 3) — is probably greater than the age of the clouds. It is unlikely, therefore, that dense clouds have achieved a chemical steady state, in spite of the apparent success of some steady state models⁴. A time-dependent approach is necessary, especially if one assumes that molecules in the gas collide and stick to dust grains and are not returned to the gas. If this is the case, a

steady state can never be achieved. The time required before this process seriously depletes molecules from the gas is about $10^3/n$ years, where n is the density of hydrogen atoms per cubic centimetre. This time is obviously quite short when the density is high, say $n > 10^4 \text{ cm}^{-3}$. Time-dependent models of the chemistry of static clouds^{5,6}, however, also fall short in some significant respects when compared with the observations, and the models clearly require further development.

The latest refinement to be included in the models depends on the recognition of the dynamical character of interstellar clouds. The spectral line widths observed from the clouds are several km s^{-1} , much broader than would be expected (about 0.1 km s^{-1}) for gas at rest at the temperatures of interstellar clouds, indicating there must be considerable motion in the gas. Therefore, turbulence, low velocity shocks, expansion or contractions must be driving the gas to supersonic velocities. For example, J. E. Dyson, T. W. Hartquist and D. A. Williams (ref. 6 and in preparation) have developed a model of giant molecular clouds in which continuous low-mass star formation creates fast winds that drive the bulk motions and erode dense clumps of gas⁷, maintaining the chemistry permanently out of steady state.

In an alternative approach, Tarafdar *et al.*¹ have considered an isolated, spherical, initially low density cloud. For gravita-

Diagram of a cardiac muscle cell, showing the conventional view of the positive inotropic action of the cardiac glycosides. Binding inhibits the Na^+/K^+ pump (i), elevating the intracellular Na^+ concentration (Na^+ (ii)) and thence intracellular Ca^{2+} (Ca^{2+} (iii)). This leads to an increase in the Ca^{2+} content of the sarcoplasmic reticulum (iv), with increased release of Ca^{2+} (v) and increase in tension (vi).

tional collapse of the cloud to occur, its thermal and turbulent pressure must be insufficient to hold up the cloud against gravity. The temperature structure of a cloud is therefore of paramount importance and Tarafdar *et al.*¹ have carefully determined the temperature profile of low density clouds. They have shown that such clouds are indeed gravitationally unstable and will collapse, without the need to involve a trigger of shocks or thermal instabilities, as had been suggested by earlier workers. They consider that this collapse explains the observed large line widths. They follow the collapse numerically, using a hydrodynamic computer code developed by Bodenheimer², and simultaneously follow the evolving chemistry in the gas, using a restricted version of the reaction network described by Prasad and Huntress³. In addition, the description indicates the loss of molecules by sticking to grains. Their results show that the extinction at the cloud centre increases as the collapse proceeds, and the molecules are freed from the major loss caused by photodissociation, with the result that their abundance rapidly build up.

The models of Tarafdar *et al.*¹ provide some very interesting conclusions. In all cases, regardless of the starting conditions, central densities attain very high values ($n > 10^6 \text{ cm}^{-3}$) within a few million years. A few percent of the cloud mass is in the form of this high density clump at the cloud centre. If these clumps proceed to form stars, a plausible rate of star formation for the Galaxy can be derived.

The chemical condition of the gas is also fully explored. Because the gas spends much of its time in a low density state, the predicted molecular abundances are dramatically affected. The excellent success of the model in describing the chemistry may be judged from the figure, which shows how the fraction of gas in the form of CO varies with extinction, A_v , along the cloud diameter (in this model, extinction is merely another measure of elapsed time in the contraction). A high C-atom abundance is also derived from these models. Observations of other atoms and molecules are also plausibly encompassed in this description. Thus, the observed differences are merely snapshots at different

Comparison of theoretical and observed variation in $N(\text{CO})$ with A_v . Modified from ref. 2, where references to the original data sets shown by the various symbols are given.

instants during the continuing collapse of clouds from a diffuse state to some dense state, from which — presumably — stars are formed. The initial diffuse clouds are all predicted to be fairly similar.

Several questions deserves further study: for example, will the high C-atom abundance drive the formation of unacceptably high hydrocarbon densities? Do clouds really evolve as rapidly as suggested? If stars do form, will the cloud remnant be entirely disrupted? Is all high density material in the form of transient clumps? The answers to such questions will surely be forthcoming. Tarafdar and colleagues have opened up a very

promising avenue in the study of the interstellar medium and star formation. □

Cellular immunology

Suppressor T cells in the network

from N. A. Mitchison

MOST of the elements of any complex control system look inwards at one another — in the immune response most lymphocytes interact with one another rather than with the outside world, just as neurones do in the nervous system. Within the regulatory compartment of the immune system the major components are helper and suppressor T cells (Th and Ts cells) which control the activity of the cytolytic T cells and antibody-producing B cells of the effector compartment. Helper T cells act directly on these effector cells but suppressor T cells usually act indirectly, via inhibition of helper T cells. It is this inhibitory interaction between suppressor and helper T cells that is analysed by two papers on pages 738 and 741 of this issue^{1,2}.

The question asked is who recognizes whom: do Ts recognize Th, or is it the other way round? This sounds simple enough, but it is made complicated by the dual nature of the receptor that T cells bear. It recognizes both antigen and a MHC (major histocompatibility complex) molecule, a property valuable to T cells because it prevents them from interacting with free antigen and ensures that they react only when it contacts other cells.

This obviously matters for cells like T cells, which operate only at short range, and is not important for B cells which secrete long-range antibody molecules. Tada has termed interactions of T cells with other cells as both 'linked' and 'cognate'. Linkage occurs via an antigen bridge connecting the antigen-binding parts of receptors on the two cells, and cognate binding of the T-cell receptor to an MHC molecule occurs on the partner cell ('cognate' means that receptors can recognize the MHC molecule as a result of repertoire selection in the thymus). In the Th-Ts interaction the 'link' must be symmetrical, that is, receptors on both cells bind to separate parts of a single antigenic structure. The direction of recognition is determined by the cognate part of the in-

teraction: if the receptor on the Th cell binds to an MHC molecule on the Ts cell, then it is the Th cell that is doing the recognizing, or vice versa.

An additional possibility is that receptor idotype (a structure on the variable part of the receptor) can substitute for antigen, in which case the linkage involves simply one receptor binding directly to another. Note that this type of binding is entirely symmetrical, because in such an interaction one cannot in principle distinguish between the idiotype structure and the receptor that binds to it.

During the past five years two substantial studies seemed to have answered the 'who-recognizes-whom' question^{3,4}: both reached the conclusion that the Ts cell contributes an MHC molecule and is therefore the partner which is recognized. It releases this molecule as a single chain, linked by a disulphide bridge to a second antigen-binding chain, which in turn establishes an antigen bridge with the Th cell. There was still some uncertainty as to whether the Th cell used its standard receptor (the 'Ti' receptor, which it uses to interact with antigen-presenting cells and B cells) for this purpose. That is where the I-J molecule, or determinant, comes in. Klein *et al.*³ argue that the Th cell does use its standard receptor, and that the I-J structure which distinguishes Ts cells from other lymphocytes is simply a modification of an MHC class II molecule — perhaps a set of determinants unique to an isolated (monomeric) MHC chain as suggested by Bodmer⁴. Despite these small differences, at that time there was general agreement about the major conclusion, and a substantial series of experiments seemed to confirm predictions made by the 'Th-recognizes-Ts' hypothesis. In addition, the hypothesis seemed to fit with the growing evidence for 'veto' cells, antigen-presenting cells within the thymus which also inactivate any Th cells that recognizes them.

These suggestions are all contradicted by the experiments reported in this issue^{1,2}, which show quite clearly that the recognition properties of T_s cells are determined not by the MHC molecules which they bear, but by selection of their receptor repertoire in the thymus. Thus, lymphocytes from allogenic chimaeras can make the soluble factor with suppressor activity (T_sF) of host type even though they do not bear host MHC molecules (they can also make donor-type T_sF, presumably because both donor and host MHC molecules are present during repertoire selection in the thymus). The conclusion is that what was previously regarded as an MHC molecule should now be reinterpreted as an anti-idiotypic which binds to that part of the T_h cell receptor that recognizes MHC molecules.

Much of the data of Klein *et al.* do not contradict this view (see ref. 3 for review). All that is needed is the substitution of an anti-idiotypic of the required type wherever an MHC molecule was identified previously as a restriction element.

Note that the concern expressed by Urcz *et al.*² about expression of I-J on macrophages must be misplaced: host macrophages are presumably needed to elicit idiotypes characteristic of the host MHC-binding site on T_h cells that in turn permit T_sF to express anti-host idiotypic binding activity.

Other possibilities exist but they all seem to involve discarding even more experimental data. Meanwhile we are still waiting for crucial molecular information, particularly about the difference between the mouse strains used to raise anti-I-J antibodies, and about the relative molecular mass 33,000 peptide that is precipitated by these antibodies⁵. If the interpretation offered in the two new reports^{1,2} is correct, the peptide must be part of the T_s cell receptor for antigen + MHC.

There is nothing new for cellular immunology in having to reinterpret quite large chunks of data; that has already happened, for instance, during the elucidation of *IR* genes. No doubt it will do T_s cells no good at a time when they are, for other reasons, running into heavy weather⁶. Nevertheless, these important papers from Japan must be regarded as a major achievement for the idiotypic network theory, and they will strengthen the view already current⁶ that T cells are even more strongly subject to network control than are B cells. □

A Cambrian enigma

Reconstructed lateral and ventral views of *Anomalocaris nathorsti*, appendage partly flexed, lateral lobes in still position. In the lateral view, a portion of external cuticle is cut away to show the arrangements of gills. For the ventral view, part of head region cuticle is cut away to show flaps and gills, and blades are omitted from the right appendage to expose the circling of mouth plates (From *Phil. Trans. R. Soc.* B309, 569, 1985).

How well do we know the fossil record? Recently H.B. Whittington and D.E.G. Briggs (*Phil. Trans. R. Soc.* B309, 569; 1985) have described in detail yet another surprise from that almost inexhaustible palaeontological treasure-house, the Middle Cambrian Burgess Shale of British Columbia (see *Nature News & Views* 302, 570; 1983 and 314, 403; 1985). *Anomalocaris*, the bizarre metazoan shown above has had a chequered scientific history; its isolated jointed appendages have been known for many years from both the Lower and Middle Cambrian of North America. They were generally regarded as the detached limbs of a large arthropod. With the discovery of complete specimens, however, a far more bizarre and enigmatic creature has emerged, with two varieties presently recognized (species or sexual dimorphs?). With a length of probably up to half a metre, it is the largest known Cambrian animal. The body was flanked by flexible lobes that served in propulsion, while gills were housed beneath lateral extensions. A single pair of appendages arose from the underside of the head to flank a remarkable jaw that consisted of a series of plates ending in sharp prongs that encircled the mouth. Although the gut contents are not identifiable, the evidence points to *Anomalocaris* being a predator.

Whittington and Briggs' account is important for our understanding of early metazoan life. Until recently, most palaeontologists believed Cambrian predators rare, exerting a negligible influence in marine communities, although some

years ago G.E. Hutchinson (*Am. Ass. Adv. Sci. Publ.* 67, 85; 1961) suggested that this was an artefact of the fossil record that favours suspension and deposit feeders with robust skeletons (Schopf, T.J.M. *Paleobiology* 4, 261; 1978). *Anomalocaris* is the latest, if most ferocious, addition to the lightly skeletonized and soft-bodied predators that have been found in the Burgess Shale (Conway Morris, S. *Phil. Trans. R. Soc.* B 307, 507; 1985). At some horizons that have yielded *Anomalocaris* there are also trilobites showing evidence of unsuccessful attack, and Whittington and Briggs speculate on how the action of the jaw apparatus can be reconciled with the damage. But some injured trilobites are not associated with *Anomalocaris* and perhaps represent the unwelcome attention of other large predators that so far have eluded discovery (Conway Morris, S. & Jenkins, R.J.F. *Alcheringa* 9; in the press).

The Burgess Shale contains an extraordinary variety of metazoans which, if found alive today, would probably be hailed as new phyla. *Anomalocaris* is no exception; despite the arthropod-like anterior appendages, the rest of the anatomy is irreconcilable with the arthropod bodyplan and the jaw apparatus appears to have no parallel in the Metazoa. It is a reminder of how little we know about the early diversification and ecology of the metazoans.

Cell biology

Yeast as the universal cell

from Ira Herskowitz

"In ten years, yeast has changed from *E. coli* with a nucleus to the universal cell." This comment by Lee Hartwell (University of Washington) opened a recent conference of yeast cell biology*, reflecting the two main recurring themes of the meeting. The first was that yeast shares with animal cells many of the molecules and processes that are the objects of intensive study in modern cell biology. It has, for example, ubiquitin, calmodulin, clathrin, endocytosis, peptide growth factors, small nuclear RNAs, retroviral elements and those staples of cell structure and function, actin and tubulin. Thus, such central problems as protein localization, function and synthesis of the mitotic apparatus, and the workings of the cell cycle can all be productively studied in yeast. The second theme was that just about any biochemical, cytological or genetic technique or experimental strategy can be applied in studies with yeast. What distinguishes it from other eukaryotic cells for studying cell biology, however, is its accessibility to the full range of both traditional and modern genetic methods. The power of these techniques to elucidate such fundamental processes as mitosis, endocytosis and the control of the cell cycle was well illustrated at the meeting.

The most powerful of the modern genetic strategies available is to produce mutations in cloned yeast genes *in vitro* and then to replace the wildtype gene with the mutant by recombination *in vivo*. This makes it possible to link biochemical information on a protein *in vitro* with cytological information on structures *in vivo* by studying the behaviour of the mutant. A model analysis of this sort has been carried out by G. Payne (University of California, Berkeley) on clathrin, which is in coated vesicles² and is believed to mediate endocytosis. An antiserum to purified clathrin allowed the gene encoding the heavy chain of the protein (*CHC1*) to be fished out from a library, disabled by mutation *in vitro* and then replaced in yeast. The first result with the *in vitro* clathrin mutant (*chc1*⁻) is that it is, perhaps surprisingly, viable, although the colonies it forms are small. Further studies should help to define the role played by clathrin in yeast. Are the mutants defective in endocytosis, in cell fusion events (such as occur in mating), or in turnover of cell surface material?

The mitotic apparatus

Much work in cell biology is focused on how the mitotic apparatus is assembled and disassembled during the cell cycle and

how it distributes chromosomes to daughter nuclei. An initial goal is to define the proteins that make up the spindle on which the chromosomes become arrayed and then to determine how they function³.

The yeast spindle is a tripartite structure, consisting of microtubules that join at one end to the centromere (the yeast version of the kinetochore of the chromosome) and at the other end to the microtubule organizing centre, the spindle pole body (analogous to the centromere)⁴. The molecular outlines of the yeast mitotic apparatus are now emerging through information from the following sources.

The central element of the structure is the microtubule, composed of tubulin. The story described by D. Botstein (Massachusetts Institute of Technology) for the budding yeast *Saccharomyces cerevisiae* and by M. Yanagida (Tokyo University) for the fission yeast *Schizosaccharomyces pombe* is the same: there are three tubulin (*TUB*) genes, two of them for alpha tubulin (only one of which is essential) and one for beta tubulin. Microtubules are needed for chromosome distribution: inactivating an essential tubulin gene by mutation has the same consequences as adding the popular anti-mitotic agents, nocodazole and benomyl. A suggestion that microtubules might also be involved in bud growth seems not to be borne out, as mutants lacking an essential tubulin gene nonetheless form buds. A crucial question in the mechanism of mitosis is that of the role of the microtubule-associated proteins, which are often speculated to play prominent roles in governing microtubule association and dissociation. They have now been identified in yeast by traditional fractionation and polymerization (F. Solomon, Massachusetts Institute of Technology), and the analysis of mutants produced by gene replacement should quickly establish what part they play.

The most exciting findings so far have been on two genes that affect the spindle pole body (P. Baum, University of Washington). It has long been hoped that some of the numerous *CDC* (cell division cycle) genes⁵ would affect structural components of the segregation apparatus, and it looks as though this might be the case for *CDC31*. The nucleotide sequence of *CDC31* shows that it has homologies to calmodulin and in particular that it contains calcium binding domains. The *CDC31* protein may therefore be a structural component of the spindle pole body with its properties of association controlled by calcium. The second fascinating gene described by Baum seems to control the number of spindle pole bodies. Remarkably, mutants defective in this gene form

extra spindle pole bodies when the *ESPI* protein is inactive — up to eight can be seen by electron microscopy. The *ESPI* gene product thus seems to stop spindle pole body assembly after each round of their duplication at each cell cycle.

Studies of the *KARI* gene indicate that it may also code for a structural component of the spindle pole body and also demonstrate a novel strategy for the use of cloned genes to generate mutant phenotypes. M. Rose (Massachusetts Institute of Technology) observed that overproduction of the *KARI* protein (achieved by placing the *KARI* gene under control by a regulated, highly expressed promoter) has lethal consequences similar to those of inactivation of the *KARI* product. In both cases there is a block in chromosome distribution. This strategy of creating a mutant phenotype by overproduction of a functional product ought to be useful in mammalian cells. It was suggested that a high level of the *KARI* protein might disrupt spindle function by 'tying up' an essential spindle component. The original mutant allele of the *KARI* gene has a distinct phenotype — nuclei fail to fuse after mating between compatible cells. Such defects have been suggested to be due to a defect in the spindle pole body^{6,7}.

Although the mitotic spindle is a symmetrical structure (at least on the cell-biological drawing board), the *ndc1* mutant described by Botstein may reveal ways in which it is not. These mutants display the remarkable aberration that in some cases the daughter cell receives both sets of chromosomes and in other cases, the mother cell receives both sets. (It is perhaps relevant that *cdc31* mutants can exhibit similar behaviour⁸.) This aberration in chromosome distribution suggests that one half of the mitotic spindle is defective in some manner. Perhaps the *NDC1* protein is a connector between the spindle pole body and microtubules. One would have to make the additional interesting speculation that the two spindle pole bodies differ from each other. Localization of the *KARI* and *NDC1* (as well as *CDC31* and *ESPI*) proteins within the spindle by direct cytological observation will be a critical test of these speculations. *ESPI*, *CDC31*, *KARI*, and *NDC1* are notable examples in which genetic analysis has turned up interesting mutants but whose further characterization relies on cytological methods that are newly available in yeast^{9,10}.

The cell cycle

Yeast genetics has traditionally been a major contributor to the elucidation of the control of the cell cycle, defining the genes necessary for the initiation, progression and exit of cells from the growth cycle to various specialized shunts, such as meiosis. The *CDC* genes, which control progression, have recently attracted particular attention because of the possibility that they may have functional homologies to

*The Cetus-UCLA Symposium on Yeast Cell Biology, was

cellular oncogenes of animal cells¹¹. There was therefore considerable interest in a report at the meeting from S. Reed (University of California, Santa Barbara) on *CDC28*, mutations that cause arrest in G₁ without any inhibition of protein synthesis, by contrast with numerous other mutations and with nutritional starvation that result in arrest in G₁ without protein synthesis and are thus less likely to reflect specific controls. The nucleotide sequences of both *CDC28* from *S. cerevisiae*¹² and the functionally related gene *CDC2* of *S. pombe*¹³ show clear homology to protein kinases and Reed reported that the *CDC28* product has protein kinase activity¹⁴. Defining its targets may thus provide insights into key regulators of the cell cycle.

Mating between *S. cerevisiae* cells of opposite mating types, a or α , involves reciprocal arrests of the mating partners in G₁ by oligopeptide pheromones, a -factor and α -factor. Understanding how these agents arrest the cell cycle provides a novel opportunity to study regulation of the cell cycle. Some of the components of this system have now been identified. The working view is that each factor binds to a receptor on the cell surface and then generates an intracellular signal that ultimately leads to arrest. The cells then go on to fuse. The *STE2* gene appears to be a component of the receptor for α -factor (D. Jenness, University of Washington), and the *STE3* gene has been argued to be a component of the receptor to a -factor. The nucleotide sequences of *STE2* (A. Burkholder, University of Washington) and *STE3* (E. Jarvis, University of Oregon) show that both code for several long hydrophobic stretches and hence exhibit hallmarks of membrane proteins. Do *STE2* and *STE3* proteins make up channels of some sort? Only the appropriate receptor components are produced in a and α cells because the *STE2* gene is expressed only in a cells and the *STE3* gene only in α cells, due to the action of regulatory proteins coded by the yeast mating type locus¹⁵. Evidence that response to a -factor and α -factor proceeds by a common intracellular signal was presented by G. McCaffrey (University of Oregon) in experiments using α mutants that produce the receptor normally found on a cells.

Regulators involved in the decision to leave the mitotic cycle and enter the pathway of meiosis and spore formation have been identified. Prior genetic analysis pointed to the *RAN1*¹⁶ product of *S. pombe* and the *RME1*¹⁷ product of *S. cerevisiae* as such regulators. Recent analysis in my laboratory confirms that *RME1* governs entry into meiosis. In particular, the *RME1* product appears to be an inhibitor of meiosis and sporulation: these processes occur only in cells whose *RME1* gene is turned off (which occurs naturally in a/α diploid cells). Determining the manner by which the *RME1* and *RAN1* products act

(as a repressor or a protease?) and identifying their targets, ought to provide insights into the early steps of meiosis.

The stage seems set to learn a great deal from yeast about fundamental cellular processes that have historically been considered within the domain of cell biology. Yeast geneticists no longer flinch at cell

biologist's jargon: clathrin, tubulin, ubiquitin — while cell biologists are learning a new three-letter code: *TUB*, *CDC*, *ESP*. This meeting, the first devoted to yeast cell biology, was well timed to show that contemporary cell biology and yeast research, both areas of great excitement, are joined for a productive future. □

Ichthyology

Filter-feeding on a grand scale

from Jared M. Diamond

ON 29 November 1984 a second specimen of the megamouth shark *Megachasma pelagios* was captured near Los Angeles, California¹. The original specimen caught off Hawaii in 1976 and possibly the most significant discovery of a marine vertebrate for a decade, constituted not only a new species and genus but also a new family within the shark order Lamniformes^{2,3}. Of particular interest are megamouth's feeding habits, which may be unique among animals and on which the Los Angeles specimen sheds further light.

Among the over 300 specimens of sharks, *Megachasma pelagios* is one of only three that are filter-feeders; the others are macropredators and scavengers. Filter-feeders strain many small food items out of water or mud either by pumping the medium through a stationary filter, as in the case of sessile invertebrates such as bivalve molluscs or polychaete worms, or by pushing the filter through the

medium, as do flamingoes and many fish. The secret of successful filter-feeding lies in filtering large volumes of medium containing high concentrations of food items. Among filter-feeders are the largest mammals and fish — baleen whales, basking sharks, whale sharks and manta rays — for which the problems of filtering enough food are acute. These large filter-feeders are constrained to live at or near the surface of nutrient-rich waters, such as coastal zones and the Antarctic.

Megamouth, which at 4.5 m in length and 750 kg in weight is one of the largest living sharks, is clearly a filter-feeder. The stomach of the Hawaiian specimen contained 1-inch long euphausiid shrimps; shrimps and deep-water jellyfish were found in the Los Angeles specimen. The shark's huge mouth is filled with hundreds of tiny teeth, none over 0.5 inches high. Its highly protrusible jaws can be extended like a hoop-net. Filtering is carried out by a unique type of gill-raker, with a core of cartilage and covered by tiny denticles.

In habitat and anatomy, megamouth is very different from the other two large filter-feeding sharks. The basking shark swims with its mouth open, near the surface of cold nutrient-rich coastal waters. It is a powerful swimmer, with a streamlined body, strongly calcified skeleton, stiff fins, strong skin, and firm muscle and connective tissue. Its filtering apparatus consists of vast gill cavities and streamlined gill-rakers, designed to support a high flow rate. The whale shark is also a strong swimmer that often feeds near the surface and can suck in and filter out water even when stationary.

By contrast, megamouth lives in deep water with lower plankton concentrations

Megamouth shark *Megachasma pelagios* captured off Los Angeles in November 1984 (Photograph courtesy of L. J. V. Compagno).

than surface waters; one specimen was taken at 125 feet or less, the other at about 540 feet. The soft loose skin, flabby muscles and connective tissue, soft cartilaginous skeleton with little calcification, and non-streamlined form suggest it is a slow, weak swimmer, and explains why megamouth is the only shark known to be attacked by the 'cookie-cutter shark', *Isistius brasiliensis*, so-called because of the neat pieces it bites out of large fish and porpoises⁴. Its inefficient filtering mechanism, with a small gill cavity, restricted internal gill apertures and non-streamlined gillrakers, is ill-suited for a high flow rate. Instead, it has a huge tongue that almost fills the mouth when closed, presumably to expel water across the filter with jaws shut.

How could such a large but weak animal, with a low-flow filter and living well below the rich plankton zone, filter enough plankton to support itself? A clue comes from the bright silvery lining of the mouth, suggesting that it is bioluminescent. The stomach contents include species that live in the deep scattering layer and that are known to be bioluminescent. Thus, megamouth may feed by holding its mouth open in the dark, attracting plankton like moths to a light trap. Some abyssal anglerfish have bioluminescent organs to attract their fish prey, but I am unaware

of a filter-feeder other than megamouth that uses light to attract plankton.

The closest parallel to megamouth's suggested feeding strategy may be found in frogmouths (family Podargidae), which are large nocturnal birds of New Guinea and Australia. Although frogmouths are well known to pounce on large insects and small vertebrates, this foraging technique fails to explain why they have a huge mouth. However, *Podargus papuensis* of New Guinea spends much time perched with its mouth wide open, perhaps using an odour to attract aerial plankton on to the sticky paste on its palate. If evidence is forthcoming to support the suggestion that megamouth sharks and frogmouths attract plankton into their open mouths by light and chemicals, respectively, the infrequency with which such behaviour has evolved will be puzzling. Why do almost all filter-feeders go to great efforts to pump water through their filters or to push their filters through water, instead of attracting their prey into their mouths? □

Atherosclerosis

Scavenger cell receptor shared

from Michael S. Brown and Joseph L. Goldstein

WHEN a blood vessel is damaged, scavenger cells (macrophages) migrate into the wound where they ingest and degrade the debris that has escaped from the bloodstream. But problems with the normal process can arise within the walls of arteries, because the macrophages ingest, among other things, the cholesterol-carrying low density lipoproteins (LDL) of plasma that have penetrated into the artery wall. The insoluble cholesterol of LDL cannot rapidly be excreted and accumulates in the macrophages as lipid droplets, converting the macrophages into 'foam cells' that contribute substantially to the mass of atherosclerotic plaques¹. Our understanding of atherosclerosis would be advanced if we knew how macrophages identify abnormal lipoproteins and other debris for ingestion in preference to normal extracellular components. Answers are emerging from studies of a cell surface receptor on macrophages that binds chemically altered proteins and on page 746 of this issue, Phillips and colleagues show that platelets release a substance that affects this receptor².

Surprisingly, normal macrophages express very few LDL receptors of the classic type that is found on fibroblasts and liver cells³. They therefore ingest native

LDL sparingly. When LDL is, however, modified chemically by acetylation, it loses the ability to bind to the classic LDL receptor, but is now recognized by another high-affinity receptor on macrophages³. The receptor-mediated uptake of acetyl-LDL leads to massive deposition of cholesterol within the macrophage^{1,3}. The receptor that mediates this uptake has been called the acetyl-LDL receptor or the scavenger cell receptor¹. It also recognizes LDL and other proteins which have been treated with agents that alter lysine residues, including succinic anhydride, maleic anhydride and malondialdehyde^{1,4}. As with acetylation, these agents increase the net negative charge of the protein. Other negatively charged compounds, such as sulphated glycosaminoglycans also bind to it. Gotto and coworkers have recently solubilized and partially purified the acetyl-LDL receptor from the mouse macrophage cell line P338D₁. By ligand blotting, they have shown it to be a protein of approximate relative molecular mass (M_r) 260,000 (ref. 5), clearly different from the 160,000 M_r LDL receptor.

Although the acetyl-LDL receptor lacks absolute chemical specificity, it is cell specific. It seems to be present only on

macrophages¹ and endothelial cells^{6,7}. Endothelial cells are not usually considered to be scavenger cells because they show little phagocytosis of particulate matter⁸, but the discovery that they have acetyl-LDL receptors resurrects the possibility that they share some scavenger functions with macrophages. In the body the acetyl-LDL receptor is particularly abundant on the endothelial cells that line the hepatic sinusoids. When fluorescent or radioactive acetyl-LDL or acetoacetyl-LDL is administered to animals intravenously it rapidly accumulates in the hepatic sinusoidal endothelium and to a lesser extent in hepatic Kupffer cells⁹⁻¹¹.

There remains a crucial question — the identification of the natural ligand for the acetyl-LDL receptor. It seems unlikely that lysine residues would be acetylated in extracellular fluid *in vivo*. On the other hand, Steinberg *et al.* have observed that LDL can be converted by chemical oxidation into a negatively charged form that binds to the acetyl-LDL receptor¹². When LDL accumulates in extravascular spaces, it might undergo oxidation, thereby increasing its net negative charge, as well as permitting uptake by the acetyl-LDL receptor of macrophages. Such a mechanism might explain the occurrence of cholesterol-loaded foam cells in atherosclerotic plaques, and also the accumulation of cholesterol in macrophages throughout the bodies of patients with homozygous familial hypercholesterolaemia. Indirect support for this hypothesis comes from the finding that LDL isolated from inflammatory tissues of rabbits has an enhanced negative charge¹³.

Phillips *et al.*² add a new twist to the story. They show that activated platelets release a substance of $M_r > 100,000$ that blocks the uptake and degradation of acetyl-LDL by macrophages, apparently as a result of competitive binding. This substance is likely to be one or more of the negatively charged proteoglycans that are stored in platelet granules and released after thrombin treatment¹⁴. Secretion of this substance might limit the ability of macrophages to clear lipoproteins from extracellular deposits. In addition, this

platelet-derived substance might serve as a chemotactic agent to attract blood monocytes to sites of tissue injury and to activate macrophages at these sites by interaction with the acetyl-LDL receptor.

The emerging story suggests that the acetyl-LDL receptor may mediate scavenger functions that are shared by sinusoidal endothelial cells and macrophages. At present, however, there is no direct evidence to link this receptor with cholesterol accumulation in atherosclerotic plaques. Possibly the physiological

ligand for this receptor is not a lipoprotein at all but some other negatively charged macromolecule, such as the one released from platelet granules⁵. The receptor is now being purified⁵, so it should soon be possible to prepare antibodies against it, thus helping to remove some of the mystery surrounding its function. □

Oncogenic intelligence

Another link in the chain

from Peter Newmark

IT CAME as a complete surprise when one chain of platelet derived growth factor was revealed to be very similar to that of the product of the *sis* oncogene and, again, when the epidermal growth factor receptor sequence was found to contain the sequence of the *erb-B* oncogene product. But, if the sequence of the *fms* oncogene product turns out to be identical to part of that of the receptor for the growth factor CSF-1, it will be no surprise, following the publication by C.J. Sherr *et al.* of highly suggestive evidence of a close relationship between the two proteins in *Cell* 49, 656; 1985. This forging of a third link between the genes for growth factors or their receptors and oncogenes will add impetus to the quest to discover whether the mutation of the factor or receptor genes is a contributory cause of human cancer.

Of the two proteins compared by Sherr *et al.*, more is known of *fms*. Like most oncogene products, it was discovered in an animal tumour virus, in this case the McDonough strain of feline sarcoma virus. A good deal has been learnt by Sherr's group about the properties of both the viral protein, which is encoded by the *fms* oncogene (*v-fms*), and the protein that is encoded by the *fms* proto-oncogene (*c-fms*) — a gene of mammalian cells and the progenitor of *v-fms*. Less is known of the functions of either protein. The oncogene product obviously transforms normal cells into tumour cells. It also comes into the category of oncogene proteins that are located on the cell surface and are associated with an enigmatic ability to catalyse the phosphorylation of tyrosine residues in proteins; a similar enzymatic activity is associated with the product of the proto-oncogene. Particularly by analogy with *erb-B*, these facts have suggested that *c-fms* encodes a growth factor receptor and that *v-fms* encodes part thereof but with a truncation or other alteration that subverts the normal function of the receptor.

But which receptor is it? The probable answer has come from studies by E R

(colony stimulating factor-1), which is a protein that stimulates the production of macrophages from their precursor cells. The factor binds specifically to cells of the mononuclear phagocytic series, including macrophages, and seems to have some characteristics that are reminiscent of the *c-fms* product.

To cement the relationship between their two proteins, Sherr's and Stanley's groups have now obtained two sets of data, which they jointly report in *Cell*. The first establishes the presence of a *c-fms*

product with an associated tyrosine kinase on the membrane of macrophages, as it should be if it is the CSF-1 receptor. The second demonstrates that antibodies to the *v-fms* product recognize a macrophage membrane protein that binds CSF-1 and has other properties of CSF-1 receptor.

Now we need sequence data. The sequences of *v-fms* and, by deduction, its product are known, but those of *c-fms* and the CSF-1 receptor are not. Only when they become available will it be possible to be certain that the *c-fms* gene encodes the CSF-1 receptor and to see what alterations have accompanied the conversion of *c-fms* into *v-fms*. As Sherr *et al.* say, there are two possibilities. One is that, parallel to the *v-erb-B* gene, *v-fms* may lack the sequence that encodes the CSF-1 binding domain of the receptor and could encode a tyrosine phosphorylating activity that is constitutively active rather than CSF-1 stimulated. But since the *v-fms* product does not seem to be seriously truncated, Sherr *et al.* make the alternative suggestion that the *v-fms* product is a competent receptor and that its delivery by tumour virus to cells that do not normally contain the receptor, particularly fibroblasts, provides them with an abnormal ability to respond to CSF-1, which fibroblasts themselves synthesize. □

Peter Newmark is Deputy Editor of Nature

Particle physics

Naked beauty seen at last

from David J. Miller

CLEAR tracks of 'beauty' particles have at last been seen. The existence of the beauty or bottom quark has been accepted ever since the discovery of the upsilon particles in 1977, but the upsilons are the 'hidden beauty' bound states of a beauty quark with a beauty anti-quark. There should also be 'naked beauty' states in which the beauty quark binds with one of the lighter 'up', 'down' or 'strange' anti-quarks, forming B mesons. There has been evidence for some time for the production of B mesons, but only from electron-positron colliding beam machines in which all of the interesting processes happen inside the vacuum pipe. Heroic attempts have been made to deduce the lifetime of the B from these data but the results are not yet completely convincing.

The figure shows the convincing example of the production and decay of a pair of

beauty particles found in a nuclear emulsion stack that had been exposed to a 350 GeV p-minus beam at the CERN super proton-synchrotron by the WA75 collaboration (Brussels, Dublin, CERN, University College and Birkbeck College, London, Torino, Rome, Bari and Nagoya with associated Japanese laboratories). All five vertices are well resolved. The p-minus meson comes in from the left on the sketch and strikes a nucleus in the emulsion. Among the tracks coming from that primary interaction vertex, the B⁻ travels about half a millimetre in the emulsion before it decays to a muon (μ⁻). Just over half a millimetre from the B⁻ decay-vertex there is a 'four-prong' vertex that is taken to be the decay point of a neutral charmed particle, a D⁰ meson. Another neutral decay is seen some millimetres from the primary vertex. This is taken to

be the decay point of an anti- B^0 meson ($\bar{B}^0$) that produces a negative charmed particle, probably a D^- , which itself decays after some millimetres, giving rise to another muon.

The process illustrated in the figure seems very simple, yet scanners using high-powered microscopes took months to put the event together, even after the primary vertex had been located. The 'needles' to be searched for are tracks made up of grains less than a micrometre across. The experiment used 80 litres of Fuji and Ilford emulsion — a 'haystack' of 8×10^7 cubic millimetres. The problem was made manageable both by surrounding the emulsion with electronic detectors which identified the candidate events that were likely to contain beauty particles and by pointing back the tracks from such events to define a search-volume of about a cubic millimetre for each candidate. To avoid overcrowding the emulsion, with lots of beam tracks in one place, it was moved periodically on a precision stage.

Many of the tracks seen in the emulsion correspond to those reconstructed from the high-resolution silicon-strip detectors that were used to predict the search volume. The muon tracks are especially important in identifying beauty candidates and for this event both of them were seen by the silicon detectors and in a downstream muon spectrometer where their momenta were measured after they had passed through a tungsten and steel wall that absorbed the other (strongly interacting) particles. The transverse momentum of the muon from the B^- was particularly large, consistent only with

beauty decay, too big to have come from the decay of a lighter charm particle. The presence of this muon, recognized by fast electronics 'on-line' within a few microseconds of the interaction taking place, gave the primary 'event trigger' that allowed all available information from the detectors to be written on magnetic tape. Analysis of the data off-line picked up the second muon from the D^- decay, which made the event a prime candidate to be notified to the emulsion scanners.

Is one event so important? Even with two beauty tracks it cannot properly measure the beauty lifetime. But the decay times estimated from it are significantly shorter than those from the electron-positron machines, a few times 10^{-13} seconds, as opposed to more than 10^{-12} seconds. The lifetime of beauty is one of the constraints on part of our standard model of the electroweak interaction. Theorists were becoming embarrassed by long beauty lifetimes. The parameters of the model (the elements of the Kobayashi-Maskawa matrix) were becoming strained beyond reasonable limits. The WA75 event suggests that, once again, experimental results may be reinforcing the simplest possible model for weak processes. The group expect eventually to find enough needles in their haystack to measure the lifetime properly. For now, it is good to know for sure that beauty particles exist. □

Ocean Drilling Program

Looking down an old hole

from the Leg 102 shipboard scientific party*

ONE of the problems of drilling is that it is virtually impossible to extract a complete core from a drill-hole and one can never be certain just what is missing. Fortunately there are a myriad of techniques available to make *in situ* geophysical measurements of the rocks exposed in the sides of a hole. Because such measurements had been so successful in characterizing young (6.2 Myr) oceanic crust at Site 504 in the Pacific, it was decided that Leg 102 should re-investigate Hole 418A on the southern edge of the Bermuda Rise (25° 02'N; 68° 04'W), from which an incomplete core was taken eight years ago as part of the Deep Sea Drilling Project. The geophysical data obtained from these 110-Myr-old oceanic basalts show some interesting differences compared with the young Pacific crust.

Undeterred by the prospect of finding a hole only 25 cm across in water over 5 km deep, the new Ocean Drilling Program's drillship *JOIDES Resolution* arrived

at Site 418 on 21 March, 1985. For the next 2½ weeks borehole geophysical measurements were made to depths of 800 m below the sea floor in the upper 500 m of basalt. The results obtained can be interpreted in terms of ageing of the basaltic crust.

Acoustic velocity and waveform logs showed relatively high compressional and shear wave velocities (4.5–6.0 and 2.1–3.4 kms^{-1} respectively) throughout the upper 500 m of the oceanic crust (layer 2), with slow values occurring in the predominant weathered pillow basalt and breccia units and fast values in the massive basalts, which would be expected to be less prone to alteration. A similar difference was shown by induction and focused electrical resistivity logs, with resistivities of 40–200 ohm-m through the pillow basalts and breccias and values greater than 1000 ohm-m in the massive units. The upper 500 m below sea floor were distinguished by unusually high gamma ray activity

and relatively high formation porosities, as determined by density and neutron porosity logs. The base of this section was marked by a sharp magnetic polarity reversal, followed by a notable low on the magnetic susceptibility log from 500 to 600 m below sea floor, then a gradual increase to the bottom of the log. Unusually for holes drilled in Layer 2, caliper logs demonstrated that the hole was 'to gauge' throughout. But perhaps most excitingly, temperature measurements indicated conductive, rather than convective, heat flow in the old basalt. This suggests a less active hydrothermal regime, a view supported by the water chemistry, which showed a difference between water within the borehole and that in the surrounding rocks, the borehole water being enriched in Ca^{2+} and depleted in Mg^{2+} and K^+ .

Our preliminary interpretation of the borehole geophysical and geochemical data is that the old crust at this site has been sealed by alteration products (clays and carbonates) within the pillow basalt units, and between layers of pillow and massive basalt, restricting the movement of pore water and causing geophysical Layer 2A now to be absent. This is in contrast to the interpretation of similar studies at Hole 504B in young crust in the Pacific. At that site, Layer 2A is present, the upper basalt is relatively porous and permeable, and observed underpressures and flow of seawater into the upper permeable zone suggest weak hydrothermal convection within the pillow lavas.

A problem facing all investigations using drill-holes is to extrapolate from the downhole log to the regional geology. Large-scale seismic experiments may be used to estimate large-scale fracturing and porosity and to determine the velocity structure, anisotropy and heterogeneity of the crust. Such seismic work may also indicate the presence of deep reflectors, for example, the boundary between extrusive and intrusive basalts within the oceanic crust. To meet these objectives, an oblique ship-to-ship seismic experiment was conducted at Site 418 using the RV *Fred H. Moore* as the shooting ship and the *JOIDES Resolution* as the receiving vessel. Shot points were located along radii and concentric circles centred on the borehole. A close-spaced seismic reflection survey was made to obtain basement topographical corrections. Seismic anisotropy and lateral heterogeneity were clearly established. Because of the techniques and equipment used, the data are of high quality, making it possible to extract evidence of deep reflectors, either within the crust, if they exist, or at the Moho. □

1985. 29 figures. Approx. 115 pages
Soft cover DM 58,- ISBN 3-540-13849-8

Volume 89

Morphology and Innervation of the Fish Heart

By R. M. Santer

1985. 54 figures. VI, 102 pages
Soft cover DM 62,- ISBN 3-540-13995-8

R. V. Krstić

General Histology of the Mammal

An Atlas for Students of Medicine and Biology

Translated by S. Forster
1985. 190 plates drawn by the author.
Approx. 415 pages
Hard cover DM 92,- ISBN 3-540-15346-2

From the reviews of the German edition:
"The present book is more than an encyclopedia, it is capable of fascinating both the specialist and the lay-reader... a work to be recommended to everyone: for research scientists working in human or veterinary medicine, biology or electron microscopy and for all those teaching these disciplines, the book is a must."

Handbook of Experimental Pharmacology

Volume 77

Chemotherapy of Gastrointestinal Helminths

Editors: H. Vanden Bossche, D. Thienpont, P. G. Janssens

1985. 62 figures, XXI, 719 pages
Hard cover DM 660,-
ISBN 3-540-13111-6

In this volume the editors and authors have critically evaluated the immense amount of data on anthelmintic drugs that is scattered throughout the literature. This review is not limited to an evaluation of the therapeutic efficacy of the more important anthelmintics, but also includes information on their pharmacology, pharmacokinetics, toxicity, and mode of action. Control strategies using mass chemotherapy or selective population chemotherapy are also covered.

Volume 78

The Tetracyclines

Editors: J. J. Hlavka, J. H. Boothe

1985. 77 figures. XIV, 451 pages
Hard cover DM 490,-
ISBN 3-540-15259-8

The editors have compiled a comprehensive review of the tetracyclines, ranging from their discovery to the present and including all the major subdivisions of these chemically important and clinically useful antibiotics. This book is unique in that it covers not only the chemical composition of the tetracyclines, but also their biochemistry and medical and non-medical applications.

What was all the fuss about?

Richard Dawkins

Time Frames: The Rethinking of Darwinian Evolution and the Theory of Punctuated Equilibria.

By Niles Eldredge.

Simon & Schuster: 1985. Pp.240. \$16.95. To be published in Britain by Heinemann in January 1986.

THE alert reader of scientific magazines can hardly fail to be aware of a widespread lay rumour of something rotten in the state of Darwinism. We have seen a spate of more or less silly books by fundamentalist crackpots, cosmologists, biochemists and BBC producers, all banging the same drum. Two quotations from reviews give the general flavour: "... a highly readable non-technical account of just why Darwinism has come to be seen as a totally inadequate account of how life came to evolve on this planet"; "An original challenge to an increasingly beleaguered orthodoxy". There is nothing original in the objections deployed by these books, just the old favourites ("The eye is too complicated to have evolved by blind 'chance'", and the rest) that Darwin himself raised — and demolished. These arguments have been repeatedly rediscovered, and the answers to them repeatedly ignored or misunderstood, during each of the decades since Darwin first discussed them. So why have gleeful rumours of a "beleaguered orthodoxy" spread particularly in the latest decade? Has there been some fresh impetus, some source of new encouragement for the old fundamentalists and fellow travellers?

Like any vigorously flourishing field of science, Darwinism has always had its in-house disputes. If these had been noticed by a wider public, it is likely that they would have been seized upon as evidence that the Darwinian "orthodoxy" was crumbling, so ready is the motivation to find such evidence. The effect is heightened if any chink of encouragement is offered by professionals on the inside of the business. I regret to say that more than a chink was offered by champions of "punctuated equilibria". The debate about this interesting little theory is a technical, parochial affair if ever there was one. It lies firmly *within* the neo-Darwinian synthesis. It is no more revolutionary than many another argument that has enriched the synthetic theory, for instance that over the "gene as the unit of selection". Yet punctuationism is widely thought to be revolutionary and antithetical to neo-Darwinism, for the simple reason that its chief advocates have said that it is; said so, moreover, in loud and eloquent voices, making frequent and skilful use of the mass media. The theory, in short, stands out from other glosses on the neo-Darwinian synthesis in one re-

spect only: it has enjoyed brilliant public relations and stage management.

Dr Eldredge is one of the two originators of the theory of punctuated equilibria. He is neither a cosmologist nor a biochemist, but a genuine expert on evolution. He has to be taken seriously, and he offers us here a pleasantly written account of the punctuation theory. The book is partisan, and none the worse for that. It is engagingly personal: one has a glimpse of what it is like to be a good palaeontologist and to love trilobites. It lapses into skipworthiness only when Eldredge indulges his predilection for woolly analogies with the social sciences, and his curious enthusiasm for someone called Frederick Teggart.

There is a useful reprinting of the original paper by Eldredge and Gould which launched the theory of punctuated equilibria in 1972. Re-reading this paper, and reading the new book, I was struck by the comparative modesty of both. The more self-aggrandizing hype seems to have been a phenomenon of the intervening years, climaxing, perhaps, in 1980 when Stephen Gould pronounced the

synthetic theory "effectively dead", and when a science journalist, sycophantic enough to deserve the title Gould's Poole, hailed "An historic conference in Chicago" which "challenges the four-decade long dominance of the Modern Synthesis". If the book signals the end of that grandiloquent era it is very welcome, for the misunderstood rhetoric of middle-period punctuationism gave abundant aid and comfort to creationists and other enemies of scientific truth, and may well have been largely responsible for the ill-informed rumour that I mentioned at the outset. It is only fair to add that both Eldredge and Gould have been latter-day bulldogs in the fight against American fundamentalism.

Darwin's own bulldog, Huxley, as Eldredge reminds us yet again, warned him against his insistent gradualism, but Darwin had good reason. His theory was largely aimed at replacing creationism as an explanation of how living complexity could arise out of simplicity. Complexity cannot spring up in a single stroke of chance: that would be like hitting upon the combination number that opens a bank vault. But a whole series of tiny chance steps, if non-randomly selected, can build up almost limitless complexity of adaptation. It is as though the vault's door were to open another chink every time the number on the dials moved a little closer to the winning number. Gradualness is of the essence. In the context of the fight against creationism, gradualism is more or less synonymous with evolution itself. If you throw out gradualness you throw out the very thing that makes evolution more

The Chinese way of bookselling — detail of a bookshop of Northern Sung appearing in a long scroll painting, Spring Festival on the River (early twelfth century AD). Publisher is Cambridge University Press, price £45, \$89.50.

plausible than creation. Creation is a special case of saltation — the *saltus* is the large jump from nothing to fully formed modern life. When you think of what Darwin was fighting against, is it any wonder that he continually returned to the theme of slow, gradual, step-by-step change?

Punctuationists are in favour of a form of jumpy evolution, but it is leagues away from the saltationism that Darwin was fighting. The punctuationists' "real gaps" in the fossil record are gaps only if you confine your digging to one place. They are all too easily confused with the sort of gaps that only a divine architect could bridge. In Darwin's sense of the term, Eldredge and his colleagues must be gradualists — they would have to be creationists if they weren't. But they believe that the episodes of step-by-step, gradual evolutionary change are sporadic, separated in space and therefore hard to find in the fossils, and separated in time by long periods of stagnation. All that the punctuationists have really done is to inject periods of stagnation into an otherwise traditional Darwinian picture of gradual evolution with allopatric speciation. Whether they are right to do so is an empirical matter that palaeontologists continue to debate. The upshot of this factual debate, whichever way it goes in particular cases, will upset nobody, and certainly not "the four-decade long dominance of the Modern Synthesis". Darwin himself would have been equally happy either way, because evolutionary change is still gradual *during the times that it is actually happening*. The punctuationists deluded themselves that they were saying something revolutionary. And it was all due to a simple verbal misunderstanding: a confusion of two senses of the word "gradual".

There is a second controversy which does, in a sense, move outside the neo-Darwinian synthesis, narrowly interpreted. This is about whether a form of natural selection operates at the level of entire lineages, as well as at the level of individual reproduction stressed by Darwin and neo-Darwinism. Eldredge is particularly involved with this now and he makes some worthwhile points, especially about the "effect hypothesis", and about the unitary status of the species as a player in the evolutionary game. But he agrees that species-level selection can't explain the evolution of adaptations: eyes, ears, knee joints, spider webs, behaviour patterns, everything, in short, that many of us want a theory of evolution to explain. Species selection may happen, but it doesn't seem to *do* anything much. After reading this book, one is left with a feeling of "What was all the fuss about?", and a suspicion that Eldredge may be left with it too. □

Unseen horizons: the future of astronomy

George Efstathiou

The Invisible Universe: Probing the Frontiers of Astrophysics. By George B. Field and Eric J. Chaisson. *Birkhäuser*: 1985. Pp.195. SwFr. 58, \$19.95.

THE unveiling of the invisible Universe represents the most significant development in astronomy of the twentieth century. Since Galileo's time, astronomers have observed the sky with optical telescopes using visible light. Professors Field and Chaisson focus on the rest of the electromagnetic spectrum — the invisible radiation which holds the clue to many of the most spectacular phenomena in our Universe.

Their account is based loosely on a major report, *Astronomy and Astrophysics for the 1980s*, which was compiled for the United States Federal Government by a committee chaired by Professor Field. In the book Field and Chaisson provide a popular account of the advances we can expect from the next generation of satellites and telescopes. The choice of subject matter is wide-ranging — from Solar Sys-

tem astronomy to high-energy particle physics — and with the strikingly beautiful colour pictures cannot fail to excite the reader's imagination. The discussion is lucid, informed and supported by a useful glossary, although in places (for example the section on interstellar molecules) it does become quite technical and probably beyond the understanding of most lay readers. Throughout the book, the glittering array of new facilities provides the central theme but, curiously, the authors do not distinguish between those that are approved, such as the Space Telescope, and those that may never be built.

In some places, the discussion is too brief to be very helpful. For example, the Field committee concluded that an explanation for the vast amounts of energy produced by quasars is one of the most important of the current problems in astronomy, and so it was disappointing to find that only a few pages are devoted to the puzzle. Nevertheless, I enjoyed this book. Anybody who wants an authoritative account of future directions in astronomy would do well to read it, and it will be especially useful to undergraduates who are thinking of doing research. □

Coming devices

C.R. Pidgeon

Free-Electron Lasers. By Thomas C. Marshall. *Macmillan, New York/Collier Macmillan, London*: 1985. Pp.191. \$24.95, £29.95.

Two years ago one could say that although many experiments had demonstrated the free-electron laser (FEL) as an amplifier of laser light, the gain threshold for actual laser oscillation in a mirrored optical cavity had only twice been surpassed. A renewed burst of activity since then has resulted in demonstrations of FEL oscillation in many countries, and at wavelengths all the way from the millimeter to the visible region of the spectrum. At the most recent meeting of the regular series of FEL conferences (Rome, 1984) it was predicted that in the near future ultraviolet, vacuum ultraviolet and soft X-radiation will be generated by FEL devices. As Thomas C. Marshall states in the present work, the FEL will be increasingly leaving the designer's laboratory and becoming available for research.

In a FEL amplifier one observes or infers the amplification of an external laser beam as it interacts with an undulating electron beam passing through the periodic magnetostatic structure of a "wiggler". By contrast, an FEL oscillator

produces a laser beam without the need for an external laser. The spontaneous radiation generated by undulating electron bunches in the wiggler is reflected back and forth between a pair of end mirrors, generating enough stimulated emission in successive electron bunches to produce and sustain a laser beam.

Marshall has provided a worthwhile treatment of the operation and characteristics of the FEL, with a useful historical and conceptual review, and bibliography. Most aspects of the subject are covered, including both single-particle (or Compton) systems and collective-particle (or Raman) systems. The author has attempted — reasonably successfully, I think — to write for the larger scientific community something between "news" and a professional review paper. The book will also be useful to the FEL community itself as a less-specialized source of information in what has by now become quite a broad and fast-moving field, though the most detailed and up-to-date information must of course still be obtained from the proceedings of the yearly workshops held on FEL physics and devices. The only slight quibble I have, perhaps inevitable for a book of this length, is that in several places quite complex results are merely quoted, without derivation or even comment from other sources. □

Thinking about the ways of science

John Ziman

Popper Selections.* Edited by David Miller. Princeton University Press: 1985. Pp.479. Hbk \$32.50; pbk \$9.95.

ANY natural scientist interested in the philosophy of science will be acquainted with the work of Karl Popper. His identification of "falsifiability" as the hallmark of a scientific theory is now so widely accepted that scientists even use it as a weapon in purely scientific controversies: "I know my theory is conjectural, but at least it could be refuted by the following experiment, whereas yours is so broad and vague that it could not be disproved" etc., etc.

Many scientists attracted to Popper's ideas will have read their way with profit and pleasure through his half-dozen or so major books, and come to appreciate the breadth and depth of his thought on the meaning and social significance of the scientific approach to the world — otherwise one would have had to be content with a version of these ideas at second hand, in one of the books that have been written about them by other philosophers. But Popper is not one of those gurus whose jewels can only be appreciated by cleaning away a mass of obscuring verbiage. Not all his writing is perfectly clear and transparent at the first reading — he is dealing, after all, with very difficult questions — but there are many passages that sum up his arguments with extreme clarity and simplicity. David Miller's selection of some of these passages is thus an invaluable introduction to the work of one of the leading thinkers of our times.

It is not difficult to understand why working scientists are drawn to Popper's philosophy. His characterization of the work of research as the evolution of a body of knowledge through a process of trial and error resonates with their own experience, both as would-be discoverers and as critics of discovery claims. This overall account of the scientific process has, of course, been attacked in detail by numerous other philosophers, but it still stands firm. Indeed, the most striking feature of Popper's thinking and writing is that it is so *robust*. He fastens on a few very solid principles, and stands firmly on them throughout — the corrigibility of all scientific knowledge, the logical force of a disconfirmed prediction, the vapidness of philosophical idealism and, in the social sciences, the absurdity of the assumption that people always behave rationally. Knock-me-down arguments are not welcomed in professional academic life, which thrives on subtlety and equivoca-

tion, but I really wonder how the modern exponents of the sociology of knowledge would answer Popper's devastation of their position, originally published 40 years ago and still entirely valid.

Of course there are situations where reliance on a few apparently sound general principles can be misleading. Popper was once led into asserting that the principle of biological evolution was not a "scientific" hypothesis because it seemed essentially tautological: biologists will be pleased to read here a passage written in 1977 where he gracefully acknowledges his error on this point. I suspect that his remarks on "The Mind-Body Problem" and "The Self" will not stand for long, as natural,

Man of principles — Karl Popper, a portrait from around 1950.

and social and behavioural scientists collaborate more closely in their accounts of consciousness and cognition. It is also surprising that the very clear conception of the "public" character of the scientific process, through the intersubjectivity of observation and the mutuality of creative criticism, which he gave in a page or two in 1945, scarcely figures in his later work. Again, his notion of "world 3" — that is, the domain of "the objective contents of thought", such as scientific theories and works of art — could have been made much more convincing and fruitful if it had been firmly related to the function of symbolic communication in human societies.

But in the end one comes back to Popper for his incisive commentary on the *strategies* of scientific and political action. He does not provide us with *rules* on which to act — indeed, his first rule would be that there are no such rules — but his critique of scientism and historicism is founded upon *precepts* which every scientist, every citizen, would ignore at their peril. □

Speechless in Java

John C. Marshall

Ancestral Voices: Language and the Evolution of Human Consciousness. By Curtis G. Smith. Prentice-Hall: 1985. Pp.178. Hbk \$14.95, £17.50; pbk \$8.95, £9.60.

THE "ancestral voices" that Kubla Khan heard in Xanadu were "prophesying war"; the voices that appear in Curtis Smith's title are those of our purported evolutionary precursors who first developed the capacity for symbolic communication. But the parallels are somewhat too close for comfort. The archaeological record, Smith conjectures, suggests that linguistically-skilled Cro-Magnon "with his superior culture and technology" exterminated speechless Neanderthal man, "his closest rival for the riches of Europe".

Like so many eminent scholars before him, Curtis Smith, a professor of biological sciences at Mount Holyoke College, Massachusetts, has failed to resist the temptation to speculate on the evolution of language and consciousness. Professor Smith's mixture is fairly conventional: fossil remains, flint tools and progressive enlargement of the cerebrum, combined with attempts to teach chimpanzees American Sign Language and to communicate with hypothetical intelligences on other planets. The problem, however, is that whilst we have undoubtedly learnt much about the structure of the brain and much about the structure of human language we still have few (or no) coherent ideas about how to relate the two. That localized damage to different parts of the brain can result in differential loss of aspects of linguistic capacity and skill places constraints upon speculation but leaves the central issue untouched. Professor Smith has no more insight into that issue — how the brains of human beings differ from those of other higher primates such that only human brains can support a syntactically-structured language — than do the rest of us.

This leaves Smith to make some none-too-accurate general remarks about the functional organization of the brain. Thus he asserts that the brain resembles "an enormous hologram" in that "all of the neural symbols used for language, visual memories, music, feelings, are stored 'everywhere' ". It may turn out that this claim is true, but it is grossly misleading to present the holographic hypothesis as already established fact; and it is even worse to do so without giving any indication of how such distributed information-storage could be compatible with the specificity of deficit that is so often observed after focal damage. Smith's convictions are rarely backed by evidence. He simply states, for example, that "amnesias are defects in the retrieval system, not actual

*In Britain published by Fontana as *A Pocket Popper*, pbk £4.95.

loss of the memories themselves" without indicating that such matters are still under active debate. He is likewise convinced that the storage and recognition of faces is a holographic process, but does not bother to mention that in (monkey) cortex there do appear to be single cells tuned to particular familiar faces. His interpretation of commissurotomy ("split-brain") patients also prejudices the outcome of current discussion. *Contra* Smith's confident assertions, there are reputable scientists who do believe that we have two brains (hemispheres) and that (in the vast majority of people) language capacity and skill is limited to one of them.

Ancestral Voices is clearly intended as a popular, "lay" book on a topic that very naturally fascinates many people well beyond the confines of the neuroscience community. All the more important, then, that a fair picture should be painted

of the *limits* of current knowledge, and of the disagreements between those who work in the area. Professor Smith's efforts do not meet these requirements. Whitney's trenchant summary (1870) of theories of the origin of language comes to mind all too often:

No theme in linguistic science is more often and more voluminously treated than this, and by scholars of every grade and tendency; nor any, it may be added, with less profitable result in proportion to the labor expended.

If, despite Whitney's pessimism, the urge to read a book on the topic remains, I would recommend that one searched for a copy of George John Romanes' Victorian masterpiece, *Mental Evolution in Man* (1888). □

John C. Marshall is in the Neuropsychology Unit, part of the Neuroscience Group at the Radcliffe Infirmary, Oxford OX2 6HE, UK.

Temporal questions

James A. Secord

The Dark Abyss of Time: The History of the Earth and the History of Nations from Hooke to Vico. By Paolo Rossi. Translated by Lydia G. Cochrane. University of Chicago Press: 1985. Pp.338. £32.25, \$35.

ANYONE familiar with the development of science in the past few decades will recognize that disciplinary boundaries are far from static. Sciences move closer to and further away from one another; they break up, disappear or regroup into new subjects and specialities. Move back 300 years, and the changes involve not only science but the whole realm of human knowledge. What, for example, do fossil ammonites have in common with Chinese writing and the Egyptian pyramids? To modern ears the question seems absurd, for these subjects now belong in very distinctive scientific specialities, and any relation between them would seem a matter of chance. But in the seventeenth century their affinity was no riddle, but a feature of intellectual life that was taken for granted. Fossils, ancient languages and relics of lost civilizations all had a place in a unified study of the past: they were "signs of time". Hence the original Italian title of Paolo Rossi's important book *I Segni del Tempo*, now available to a wider audience in an English translation.

The objects grouped together here were also "signs of time" in another sense, as indications that the world might be far older than was generally thought. It is difficult for readers steeped in the time-scale of modern geology to recapture the threat that seemingly limitless time posed to men of science in the late seventeenth and early eighteenth centuries. The Copernican revolution and its consequences are familiar

from many historical discussions. But as Rossi notes, "there has been no such insistence, in the same way and with the same intensity, on other, no less decisive changes" — notably our perception of time. In the late seventeenth century, the direct and best testimony on the early ages of the world's history — the Bible — rendered an estimate of some few thousand years since the beginning not only intellectually respectable, but almost inescapable. By the end of the eighteenth, scholars looked down into what Buffon called "the dark abyss of time", and in advanced circles an age for the Earth of millions of years had become a distinct possibility. The Bible was being replaced as a secure source of knowledge by broken fragments of strata, old legends and cryptic languages. The old authority had provided at least the possibility of a single coherent narrative for the history of the world; the new ones could only be deciphered piecemeal and with difficulty.

As Rossi demonstrates, this change held major consequences for the organization of knowledge. In Genesis, the world commenced in the space of a few days. This meant that the history of the Earth and the history of man could be studied as one subject, for the two histories were almost precisely coextensive. This is a basic point, but one all too often set aside by those concerned with finding the roots of modern scientific disciplines. For instance, Robert Hooke, John Woodward, William Whiston and Thomas Burnet are familiar names in the history of geology. Rossi shows that their writings need to be read alongside the works of less familiar authors such as William Warburton, Isaac de La Peyrère and Martino Martini. Some of these men are well known in accounts of the origins of other disciplines (Egyptology, for example), while some have fallen into obscurity. By rescuing them from oblivion and reconstructing the character of their original concerns, Rossi traces the

contours of a fascinating and alien map of knowledge.

The Dark Abyss of Time looks particularly closely at those who maintained the authority of scripture against Hobbits, atheists, sceptics, pre-Adamites and others ready to use new empirical findings to undermine religious certainty and the social fabric. Discussion of these "defence mechanisms" is divided into three parts, devoted respectively to Earth history, human history, and barbarism and language. Rossi is especially concerned to show how each of these topics became entwined in the making of a single major text in early modern intellectual history, Giambattista Vico's *Nuova Scienza*, published in its final form in 1744. Usually hailed as a founding figure of historicism and a precursor of Benedetto Croce, Vico appears here in dialogue with contemporary figures and themes. With scholarly finesse, Rossi depicts the author of the *Nuovo Scienza* picking his way "across the scorching hot, difficult terrain" of controversies about the origin of man and the Earth. Far from being an isolated forerunner, Vico can be seen charting a new path through territory that had been an intellectual battleground for decades.

This is an impressively researched book, but one with very few concessions to students or non-specialist readers. (A good introduction is available in the first two chapters of Martin J. S. Rudwick's *Meaning of Fossils*, recently reissued in paperback.) Some of the difficulties are simply a matter of style, especially as the analysis has a tendency to loose momentum in lengthy summaries of cosmological theories. Individual chapters are not clearly connected, and have something of the character of separate essays. Moreover, the main thrust of the argument is occasionally obscured by traces of the forward-looking disciplinary history that most of the book rightly questions. Chapters on Kelvin and the age of the Earth problem (and indeed, those on Buffon and James Hutton) seem especially out of place. The preface makes the real point of the book clear.

While placing Vico in a fresh perspective, Rossi has made a major foray into a vast and unexplored territory in the literature of early modern science, pointing a way that others will want to follow. At first glance, his book may seem to deal with a variety of subjects, many not obviously relevant to the history of science. As a result, there is a real danger that readers concerned with the development of a single discipline will turn only to those chapters that immediately interest them. Resist the temptation, for such an approach perpetuates precisely those intellectual blinkers that so frequently limit an appreciation of other ways of seeing the world. □

Oblateness of the Sun in 1983 and relativity

R. H. Dicke, J. R. Kuhn & K. G. Libbrecht*

Joseph Henry Laboratories, Physics Department, Princeton University, Princeton, New Jersey 08544, USA

Measurements of the solar oblateness obtained during 1983 from Mount Wilson, California, yield a value with an upper bound only half of that observed in 1966. This difference may support the conjecture that the solar quadrupole moment slowly oscillates. A knowledge of the character of such an oscillation, if it occurs, would be needed to test Einstein's relativity theory using Mercury's orbital motion.

THE motion of the perihelion of Mercury's orbit provided the first and potentially one of the most important tests of Einstein's general relativity theory, but because of uncertainty concerning the solar quadrupole moment, this test has long been in doubt. In 1966, a measurement of the solar oblateness^{1,2} gave a value³ of $\Delta r = r_{\text{eq}} - r_{\text{p}} = 41.9 \pm 3.3$ arc ms (or 30.6 ± 2.4 km) for the excess equatorial radius of the Sun, that is the fractional equatorial excess of $\Delta r/r = 4.34 \times 10^{-5} \pm 0.34 \times 10^{-5}$. This seemed to imply a solar quadrupole moment large enough to cause a significant rotation of Mercury's perihelion.

This oblateness was first interpreted¹ as the effect of a rapidly rotating solar core, but the indication that the distortion was rotating rigidly across the Sun's surface with a 12.38 ± 0.10 day sidereal period^{3,4} cast doubt on this interpretation. It seemed more likely that the distortion resulted from a strong magnetic field, primarily toroidal, in the solar core rotating with this period⁵⁻⁷. Such an explanation could permit long-period toroidal oscillations of the core. It has been speculated that the sunspot cycle might result from a magnetic field generated by such an oscillation⁶. If so, the solar oblateness might oscillate, varying with the sunspot cycle. This test of general relativity must take such a variation into account, if it occurs. There is evidence that the solar cycle is associated with a precisely tuned oscillator deep in the Sun^{6,8}.

In 1975 a substantially smaller solar oblateness was reported⁹ and Hill *et al.*¹⁰ have suggested recently that the spectrum of solar oscillations they have found implies a rapidly rotating solar core and a significant quadrupole moment.

More recently, observations of the 5-min oscillations have given a core rotation rate roughly twice that of the solar surface, a core rotation which is too slow to yield a quadrupole moment significant enough for the relativity test¹¹.

1983 observations

During 10 April to 27 September 1983, measurements of the Sun's shape were obtained (~ 8 h per day) by one of us (K.G.L.) on Mount Wilson, California, with an improved version of the Princeton solar oblateness telescope which had been used in 1966 to measure the oblateness of the Sun². As in the earlier version of the telescope, the Sun's image is projected on one of three occulting disks of different diameter, exposing 9–20 arc s at the Sun's limb. This exposed limb is scanned at ~ 10 Hz using a rotating wheel containing two diametrically opposed 2° apertures to look for the variation in the light flux with angular position. An ellipticity of the solar disk would cause a second harmonic variation of the light flux with angular position on the limb. But at least part of such a variation could result from a 'brightness signal', a variation of the brightness of the solar disk with angular position.

Mount Wilson is better than the Princeton site in one important aspect: it yields a much greater fraction of days with a clear

sky. But in another aspect it seems to be less satisfactory: at the Princeton site the flat grassy terrain apparently resulted in a symmetry in the locally induced atmospheric distortion of the Sun that simplified the data analysis, this symmetry was not present in the Mount Wilson data, probably because of the mountainous terrain.

The principal improvements made to the instrument are (1) in the modified instrument, the light flux from the partially occulted Sun is averaged in 128 channels 1.41° wide (in 1966, only the second harmonic sine and cosine distributions of the light flux were measured). (2) The servo system centering the Sun's image on the occulting disk is based on a new, significantly improved, technique. It includes both fast and slow (integrating) servo loops. (3) The two diametrically opposed scanning apertures are the same size. This eliminates from the total light flux, in first order, signals induced by small solar-image displacements. (4) Measurements are made at eight angular positions of the vertically mounted telescope, eliminating telescope errors up to the 16th harmonic. (5) The measurements are made simultaneously in two wide colour bands centred at 'green', $0.53 \mu\text{m}$, and at 'red', $0.80 \mu\text{m}$. These bands are, respectively, 0.08 and $0.30 \mu\text{m}$ wide.

The light flux measured at 128 angular positions permits the direct detection and rejection of channels containing the signals from substantial facular patches. A channel is rejected (for the whole day and for all three disks) if the daily mean of the excess signal in the channel exceeds 3σ . (In 1966, corrections for faculae were made indirectly, by least squares, assuming that the facular signal was proportional to the area of a facular patch.)

Using the 1983 data, the new instrument has permitted a direct determination of the facular contrast near the solar limb by Libbrecht and Kuhn¹². The variation of the facular signal with the amount of exposed limb is consistent with the 1966 results¹³. Evidence for a fourth harmonic variation of the effective temperature about the solar limb with an amplitude of $0.6^\circ \pm 0.1^\circ$ has been found in the 1983 data by Kuhn *et al.*¹⁴.

As in 1966, the second harmonic corrections for astigmatic mirror errors are made by combining data obtained with the mirrors in four different combinations of positions, the primary and secondary mirrors each being in two positions 90° apart, and then including the four astigmatic mirror parameters in the least-square fits to the data.

Geometrical optics provide an inadequate description of the mirror-induced distortion of the Sun's image: for the distortion parameters obtained from the least-square fits depend sensitively on both the colour and the amount of exposed limb. It seems likely that the mirror distortion is a diffraction effect resulting from $\lambda/20$ roughness of the mirror surfaces on a scale of a few centimetres.

After the above correction is made, a small residual error remains in the correction for the primary mirror. It is eliminated by assuming that the mirror distortion is a function of the angle of incidence of sunlight on the mirror and including this type

* Present address: Solar Astronomy 264-33, California Institute of

Fig. 1 Green solar oblateness. The values of Δr (in arc ms) derived from equation (3) are plotted for both colours and each solar-hour angle bin as a function of the exposed solar limb (in arc s).

After eliminating the channels contaminated by identifiable facular brightness signals, the second harmonic sine and cosine components of the light flux are obtained by least squares from the data, with the angular coordinate chosen to be zero at the terrestrial north point on the solar disk (not the solar pole). After dividing by the solar brightness at the edge of the occulting disk (and reversing the sign of the cosine component), twice the amplitudes of the sine and cosine components are expressed in arc ms and are designated Δr_d , the 'diagonal' component, and Δr_v , the 'vertical' component, of the solar ellipticity.

These two ellipticity components, corrected for mirror errors, are also corrected for the distortion induced by the refraction of a laminar atmosphere and are averaged for each day in six solar-hour angle bins, 20° wide, ranging from mean solar-hour angles of -50° to $+50^\circ$. In the discussion below, these six bins are designated $h = 1, 2, \dots, 6$, respectively.

The three occulting disks are designated $d = 1, 2$ and 3 and expose annuli at the solar limb with the seasonal mean widths for red of $\delta R = 18.1, 13.2$ and 9.2 arc s respectively and for green $\delta R = 20.4, 15.0$ and 10.3 arc s. These annular widths are defined by $\delta R = F/I$ where F is the light flux per degree past the disk and I is the solar brightness at the edge of the occulting disk expressed in flux units per deg arc s.

For an oblate Sun with oblateness $\Delta r = (r_{eq} - r_p)$, the solar oblateness contributes $\Delta r \sin 2P$ and $\Delta r \cos 2P$, respectively, to the diagonal and vertical components of the ellipticity. Here P is the counterclockwise position angle of the solar north pole relative to the north point on the solar disk and ranges from -25° to 25° during the observational period.

Atmospheric distortion

The distortion of the Sun's image by the Earth's atmosphere, assumed to be uniformly laminar, is not the only atmospheric distortion of the Sun. The temperature inhomogeneity of the air, primarily near the observatory, also distorts the Sun. This leads to the displacement of the time-averaged position of any stellar image and the spreading of the point image into a distorted seeing disk. We are concerned here with the time-averaged position and ellipticity of the seeing disk, the two dominant contributions to the elliptical distortion of the solar image having their origin in this local temperature inhomogeneity. They are called, respectively, the 'cylindrical lens' distortion and the 'anisotropic seeing' distortion². These are the two lowest order (dominant) terms in the distortion obtained from an expansion of the solar brightness, $I(x)$, in moments of the distorted seeing disk.

The cylindrical lens distortion is independent of the limb

Table 1 Results of least-squares fits, equation (3)

Disk	Bin	Δr	D	Δr	D
1	1	26.3	33.6	23.9	37.0
1	2	23.6	15.1	22.9	12.9
1	3	22.6	3.5	22.9	-0.8
1	4	22.5	-1.4	22.4	-4.3

3	2	19.8	7.6	18.9	10.3
3	3	13.5	2.0	17.9	1.6
3	4	17.2	4.4	21.9	1.5
3	5	16.2	9.7	18.0	3.0
3	6	12.9	19.4	7.4	12.3

distortion is proportional to the logarithmic radial derivative of the solar brightness at the edge of the occulting disk. For disks $d = 1, 2$ and 3 this is respectively for the red colour band:

$$S(d) = 1, 1.31 \text{ and } 1.84 \quad (1)$$

normalized to unity for disk number 1. For green the corresponding values are:

$$S(d) = 1, 1.28 \text{ and } 1.75 \quad (2)$$

respectively. These values are obtained from limb-darkening curves for these colours¹⁵.

For the vertical component, the atmospheric contribution to the apparent solar ellipticity is not statistically separable from the true solar oblateness, for $\cos 2P$ varies relatively little through the observing period. Another quite different difficulty with the vertical component of the data concerns the off-axis astigmatic error of the primary mirror. This cannot be determined from the mirror cycling, but it affects only the vertical component of the distortion. Because of these difficulties, the analysis discussed below is based only on the diagonal component of the ellipticity.

The contribution of the solar oblateness to the diagonal component of the solar ellipticity, $\Delta r \sin 2P$, can be determined by least squares using the known seasonal variation of $\sin 2P$. This determination of Δr can be made for each of the six solar-hour angle bins for each of the three disks and for each of the two colours by fitting

$$\Delta r \sin 2P + D \rightarrow \Delta r_d \quad (3)$$

Here $D(h, d)$ is interpreted as the seasonal mean of the local atmospheric contribution to Δr_d . To interpret Δr as the solar oblateness may be premature. There are two reasons for caution. First, there may be a fortuitous $\sin 2P$ seasonal variation in the atmospheric distortion of the Sun. Second, the excess light flux in the equatorial part of the Sun may be due, at least in part, to an excess solar brightness near the equator.

The results of the least-square fits, equation (3), to the diagonal component of the ellipticity are given in Table 1. The derived values of the Δr are plotted in Fig. 1 as a function of exposed limb for each bin. Here, and in Table 1, Δr and D are expressed in arc ms. The means of the standard errors of Δr are 3.6 and 4.0 arc ms for red and green, respectively. For D the mean errors are 1.9 and 2.0 arc ms respectively.

In the 36 fits, equation (3), 3σ deviations are much more numerous than the 6 expected with a normal distribution of errors. It is found that the 30 excess large deviations all occur

may be abnormal and that they should be eliminated from the original list of 131 days with data. With the criterion that there are 2 or more 3σ deviations present, the 6 days with day numbers 98, 99, 129, 137, 159 and 175 are eliminated from the fit, equation (3), for the results given in Table 1 and in Fig. 1.

Note that the large variation of the atmospheric distortion D (as a function of h for fixed d) is not seen in Δr . Thus, it is unlikely that the atmospheric distortion has a fortuitous $\sin 2P$ dependence on time. The question of a 'brightness signal' contribution to the signal is discussed below.

For the hour angle bins $h=1$ and 6, the Sun is fairly low in the sky and the atmospheric distortion is large. (Note the large values of $D(1, d)$ in Table 1.) The data in bins 1 and 6 may introduce both a systematic statistical bias and excess noise. In the analysis below, these bins will be dropped, but the analysis will also be carried out with these bins included.

We assume that the locally induced atmospheric distortion of the Sun, $D(h, d)$, consists of the sum of two parts, the cylindrical lens distortion, $C(h)$, and the anisotropic seeing distortion, $S(d)A(h)$, where $S(d)$ is given by equations (1) or (2). The least-square fit

$$\Delta r(d) \sin 2P + C(h) + S'(d)A(h) \rightarrow \Delta r_d \quad (4)$$

combines data from all three disks and is computed for each of the two colours. The oblateness $\Delta r(d)$ is a function of disk number to allow for the possibility of a contribution from a 'brightness signal'.

To test the atmospheric distortion model, $S'(d)$ is included with $C(h)$, $A(h)$ and Δr to be varied in the least-squares fits. The results obtained for the ratio $(S'(3)-1)/(S'(2)-1)$ are 2.77 ± 0.35 and 4.1 ± 1.1 respectively for the red and green signals and are in satisfactory agreement with the ratio 2.71 obtained from equations (1) and (2). Consequently, these equations are used when computing the corrections for atmospheric distortion, using equation (4).

The results obtained from equation (4) for red are $\Delta r(d) = 21.7 \pm 1.7$, 18.3 ± 1.7 and 16.6 ± 1.7 for $d=1, 2$ and 3, and for green, 22.0 ± 1.9 , 18.8 ± 1.9 and 19.2 ± 1.9 arc ms. Note that, independently of the colour and the disk number, the six values of Δr do not differ significantly from their mean. For $C(h)$ and $A(h)$ the results are given in Table 2. The corresponding mean

Table 2 Atmospheric distortion (arc ms)

	h	2	3	4	5
Red	$C(h)$	23.0 ± 4.1	8.8 ± 4.1	-6.3 ± 4.2	-24.9 ± 4.3
Red	$A(h)$	-8.6 ± 2.9	-3.0 ± 2.9	6.2 ± 3.0	19.3 ± 3.0
Green	$C(h)$	12.1 ± 4.9	-4.0 ± 4.9	-13.4 ± 5.0	-19.8 ± 5.1
Green	$A(h)$	-1.9 ± 3.5	3.2 ± 3.5	8.3 ± 3.6	13.2 ± 3.7

estimated post-fit errors in the data points are for red, 18.8 ms, and for green, 20.5. The number of data points (20° binned means) is 1,359.

The four (or six) bins of data for each colour and disk, corrected for local atmospheric distortion using the results in Table 2, are averaged to form sets of daily averages. Only days for which data exist for all three disks are kept, a total of 121 days for the daily means of bins $h=2$ to 4.

Brightness signal

To compute the brightness signal contribution to the apparent solar oblateness, we assume that the green brightness signals are greater than the red by a factor λ , to be determined. For excess light flux resulting from faculae, we measure $\lambda = 1.6$ and for a small change in the photospheric temperature we expect a value of 1.5.

The daily mean values of the diagonal component of the solar

parts, a shape signal S and a brightness signal λB where $\lambda = 1$ for red.

The mean value M and the semi-difference D of the green and red signals are:

$$M = S + 0.5(\lambda + 1)B \quad (5)$$

$$D = 0.5(\lambda - 1)B$$

The colour difference D provides a measure of the brightness signal for each of the three disks.

The red and green day-to-day fluctuations (noise) are mainly in the shape signals. The variances of M , computed from the residuals after removing the fitted ellipticity, are 9–30 times as great as those of D . The 3×3 covariance matrix of D apparently requires two separate brightness signals common to all three disks and a low noise level for disks 1 and 2. The brightness signal is strongest in D_1 (disk 1) which is adopted as one of the 2 signals. The second $D' = D_2 - 0.70 D_1$ is orthogonal to D_1 .

The least-squares fit

$$\Delta r \sin 2P + c_1 D_1 + c_2 D' \rightarrow M \quad (6)$$

is used to fit simultaneously for the oblateness and the two components of the brightness signal. The results are given (in arc ms) in Table 3. The last column is the estimated standard error of the daily means of the solar ellipticity, M .

Table 3 Least-squares fits for the solar oblateness and brightness

Disk	Δr	C_1	C_2	σ
1	20.9 ± 1.9	2.80 ± 0.38	1.49 ± 0.78	10.36
2	18.5 ± 2.0	1.73 ± 0.41	0.69 ± 0.84	11.16
3	18.3 ± 1.8	1.20 ± 0.36	0.22 ± 0.75	9.87

The first brightness term is statistically significant for all three disks, but it contributes very little to the apparent oblateness of the Sun. This brightness varies on a timescale of 1 day but is not apparently concentrated at the equator or pole.

In Table 3, the mean of the three values of Δr is 19.2 ± 1.4 . The deviations of the three values of Δr from the mean are not statistically significant and these deviations provide no evidence for the existence of some additional (unmodelled) brightness signal.

The factor λ in equation (5) can be evaluated as $\lambda = (c_1 + 1)/(c_1 - 1)$ from the first line of Table 3, neglecting D' . This gives the result $\lambda = 2.1 \pm 0.3$, (-0.2). If the same fit, equation (6), is made using the daily means of the solar ellipticity which include the bins 1 and 6, the results for Δr are: 23.7 ± 1.8 , 19.2 ± 1.8 and 18.7 ± 1.8 ms.

The above formal standard deviation of the mean solar oblateness, 19.2 ± 1.4 arc ms, is not a realistic measure of the error. There could be a seasonal variation in the atmospheric distortion that would add to or subtract from the apparent oblateness, perhaps 1–3 arc-ms. A much larger variation seems to be precluded by the absence of a marked $\sin 2P$ variation in the various weather parameters and in the declination of the Sun.

A more serious problem is the possible existence of another, colour-independent, brightness signal, for which $\lambda = 1$. Such a signal would escape the above analysis. There is no evidence for the existence of such a signal, for the oblateness is seen to be substantially independent of disk number. Nonetheless, a small signal of this type could exist and increase the error of the oblateness determination.

To include the effect of such a signal, we use the least-squares fit

$$\Delta r \sin 2P + BE(d) + c_1(d)D_1 + c_2(d)D' \rightarrow M \quad (7)$$

Here the second term is the new brightness signal and the third and fourth terms are those previously discussed. We assume that the colour-independent brightness signal is proportional to the exposed limb and this factor is $E(d) = 1, 0.73$ and 0.50 . The

Fig. 2 The power spectrum of the residuals of M_2 (disk 3), obtained by removing the fitted value of $\Delta r \sin 2P$, from M . The vertical lines give the frequencies of the first six harmonics of the 1966 frequency, 0.07804 per day.

It gives the results $\Delta r = 15.4 \pm 4.1$ and $B = 5.2 \pm 5.3$ arc ms. Note that the brightness signal B is not statistically significant and that the change in the oblateness is only 1 standard deviation (s.d.). Nonetheless, the inclusion of this additional brightness term increases the error of the oblateness substantially, and the oblateness could be low enough to make the solar quadrupole moment negligibly small. If the daily means of the solar ellipticity which include the bins $h=1$ and 6 are used, the results $\Delta r = 13.0 \pm 3.9$ and $B = 10.2 \pm 5.0$ are obtained.

12.38-day rotational period

As noted above, the 1966 observations of the solar ellipticity were best interpreted as the effect of a solar distortion rotating rigidly over the surface with a (sidereal) period of 12.38 days. The first three harmonics of the synodic frequency, 0.07804 ± 0.0006 per day, appeared in the power spectrum of the residuals (after subtracting the fitted oblateness term). This periodic signal is much weaker in the 1983 data, if it is present at all.

The power spectrum of the residuals of M_2 (disk 3) is shown in Fig. 2. The vertical lines give the frequencies of the first six harmonics of the 1966 frequency, 0.07804. The first two harmonics may be present in the 1983 data but these two frequencies are not the two most prominent peaks in the power spectrum. The first harmonic is also present in M for the other two disks, where the noise level is higher, and in D_1 where the amplitude is 1.0 ms, but the error is only 0.3 ms.

A least-squares fit to the above two peaks for a rigidly rotating distortion yields a rotational frequency $f = 0.0792 \pm 0.0005$ per day, in good agreement with the frequency obtained from the 1966 data³. However, the amplitudes of the first two harmonics of the fitted function are only one-fifth and one-half of those obtained from the 1966 data.

In the power spectrum, there are four strong peaks for which we have no explanation. Could some of the other peaks be aliases of these four peaks (arising from the complexities of the window function due to missed observational days)? This is unlikely, for the aliases are very weak, with powers only a few per cent of the powers of the main peaks in the spectrum.

Despite the occurrence of the harmonics of $f = 0.0792 \text{ yr}^{-1}$ in the power spectrum, we do not believe that the existence of the 12.4-day rotational period in the data has been demonstrated. A much stronger case for the existence of this rotational signal was made using the 1966 data^{4,16}.

Conclusions

Assuming that the brightness signal is colour dependent, the value of the oblateness of the Sun obtained in 1983 is 19.2 ± 1.4 arc ms, where the error is only a formal s.d. A seasonal variation of the atmospheric distortion (in the form $\sin 2P$) might occur. It could have either sign and contribute an error to the oblateness determination, perhaps as great as ± 3 ms. If there should also be a colour-independent brightness signal proportional to the exposed limb (in addition to the colour-dependent one) the value 15.4 ± 4.1 would be obtained for the oblateness, where the error is again only formal. For both of these possibilities the 1983 result for the oblateness is $\ll 42 \pm 2$ ms obtained in 1966.

Unless there is some support for the existence of a colour-independent brightness signal, it seems reasonable to adopt 19.2 ± 1.4 ms for the oblateness, with the proviso that a more believable error might be ± 4 ms. Of this oblateness, 7.8 ms results from surface rotation (a centrifugal distortion of surface layers)¹⁷. The remainder, 11.4 ms (or $\Delta r/r = 1.2 \times 10^{-5}$), is associated with a quadrupole moment $J_2 = (2/3)(\Delta r/r) = 7.8 \times 10^{-6}$ which is only one-third of the value obtained from the 1966 observations.

The 1983 results seem to be compatible with the conjecture that the Sun has an oscillating quadrupole moment, but an extended series of observations would be needed to confirm this conclusion. The implications of the solar oblateness for Einstein's theory of gravitation will be unclear until the solar quadrupole moment and its possible variation with time are measured. The implications of an oscillating solar core for the solar cycle, and for the generation of solar magnetic fields, could be profound.

The classical astronomical test of Einstein's theory derived from the excess rotation of the perihelion of Mercury's orbit requires a knowledge of J_2 and its variation with time. If variation of J_2 were periodic with the sunspot cycle, a 22-yr mean would be adequate. More recent planetary radar observations of Mercury's motion can use time averages on a decade timescale. A Mercury satellite orbiter could reduce this timescale markedly and permit an observation of the time variation of the perihelion rotation. If the time variation of J_2 were also known, this would permit an accurate test of this relativistic effect on a short timescale¹⁸.

Amino-acid sequence of the catalytic subunit of the $(\text{Na}^+ + \text{K}^+)\text{ATPase}$ deduced from a complementary DNA

Gary E. Shull*, Arnold Schwartz† & Jerry B. Lingrel*

Departments of *Microbiology and Molecular Genetics and †Pharmacology and Cell Biophysics, University of Cincinnati College of Medicine, 231 Bethesda Avenue, Cincinnati, Ohio 45267, USA

We have isolated and characterized a complementary DNA for the catalytic subunit of the sheep kidney sodium/potassium-dependent ATPase. The 1,016-amino-acid protein seems to have eight transmembrane domains. The apparent ouabain binding site is located at the extracellular junction of two transmembrane domains and is linked to the phosphorylation site by a 60-amino-acid conserved sequence that may be a major channel for energy transduction.

It is known that the sodium/potassium-dependent ATPase $[(\text{Na}^+ + \text{K}^+)\text{ATPase}]$ is an integral membrane protein that directly couples the hydrolysis of ATP to the vectorial transport of Na^+ and K^+ across the plasma membrane. This in turn produces the electrochemical gradient of Na and K which is the primary source of energy for the active transport of various nutrients¹, the action potentials of excitable tissues such as muscle and nerve² and the regulation of cell volume³. The enzyme consists of a large catalytic subunit (α), with a relative molecular mass (M_r) of 110,000, and a smaller glycoprotein subunit (β), of unknown function, with an M_r of ~55,000 (ref. 4). The ATP-binding site⁵ and the phosphorylation site⁶ are both located on the cytoplasmic side of the α -subunit and a binding site for cardiac glycosides such as digoxin and ouabain is located on the extracellular side⁷. There is much interest in the location and structure of the ouabain binding site because it is thought to be the pharmacological receptor site for the digitalis class of drugs⁷⁻¹¹.

Considerable effort has been directed at determining the molecular mechanism of active cation transport. The catalytic subunit can exist in at least two conformational states and it is apparently during the transition between these states that Na^+ and K^+ traverse the membrane^{12,13}. This conformational transition is extensive and seems to involve at least 80 amino acids which undergo a transition between α -helix and β -sheet¹⁴ during each cycle of phosphorylation and dephosphorylation. Because the binding of Na^+ and K^+ , cardiac glycosides and ATP all influence the conformational state of the enzyme¹³, there seems to be communication throughout the molecule, involving cytoplasmic, transmembrane and extracellular domains. In addition to the $(\text{Na}^+ + \text{K}^+)\text{ATPase}$ there are several other eukaryotic plasma membrane proteins involved in primary active transport. These include the Ca^{2+} -ATPase¹⁵, the $(\text{H}^+ + \text{K}^+)\text{ATPase}$ ¹⁶, and an H^+ -ATPase found in fungi¹⁷. The available data suggest similarities in their structures and enzymatic mechanisms and there is evidence that they have evolved from a common ancestor¹⁸. Structural comparisons of these transport ATPases may help to elucidate their function.

Here we describe the isolation and characterization of a complementary DNA clone containing the entire coding region of the messenger RNA for the catalytic subunit of the sheep kidney $(\text{Na}^+ + \text{K}^+)\text{ATPase}$. The complete amino-acid sequence has been deduced and a comparison with the Ca^{2+} -ATPase sequence reveals extensive regions of homology. This and some other comparisons have allowed us to identify several possible functional domains, including a conserved sequence of ~60 amino acids which is likely to be a major component of the energy transduction system. This sequence spans the membrane and is bounded at one end by the phosphorylation site and at the other by the apparent ouabain binding site.

Isolation of cDNA clones

Sixteen tryptic peptides of the sheep kidney $(\text{Na}^+ + \text{K}^+)\text{ATPase}$ α -subunit have been characterized previously¹⁹ and two of these peptides, T14 and T16, were used to derive oligonucleotide hybridization probes. T14, located at the ATP-binding site, contains the sequence Met-Lys-Gly-Ala-Pro and T16 contains the sequence Val-Phe-Gln-Ala-Asn-Gln-Asp. A 14-base probe, 5' G-G-(A,G,T,C)-G-C-(A,G,T,C)-C-C-(C,T)-T-T-C-A-T 3', which was a mix of 32 oligonucleotides, and a 20-base probe, 5'-T-C-(T,C)-T-G(A,G)-T-T(A,G,T,C)-G-C(T,C)-T-G-(A,G)-A-(A,G,T,C)-A-C3', which was a mix of 256 oligonucleotides, were derived from T14 and T16, respectively. A library of 50,000 colonies constructed with size-selected cDNA prepared from sheep kidney poly(A)⁺ RNA was screened separately with each probe. Twelve colonies gave signals with both oligonucleotides and plasmid DNA from these clones was isolated and analysed by restriction mapping and blot hybridization analysis.

The size of the cDNA inserts ranged from 2.30 to 3.65 kilobases (kb) (data not shown). Eleven of the twelve clones had a 1.85-kb *Pst*I fragment, which corresponds to the 3' end of the mRNA, and a variable *Pst*I fragment ranging in size from 0.45 to 1.8 kb, which corresponds to the 5' end of the mRNA. In each case a 0.44-kb *Bam*HI restriction fragment gave strong signals with both oligonucleotides when analysed by blot hybridization. To confirm the identity of these clones we first determined the nucleotide sequence of αNKA1 in the region containing homology to the hybridization probes (see Fig. 1a for the restriction map of αNKA1 and the sequencing strategy). The nucleotide sequences encoding T14, T16 and several other known tryptic peptides of the sheep enzyme were identified. All 16 of the known tryptic peptides have been identified in the full sequence described below.

Nucleotide and amino-acid sequences

The complete nucleotide sequence for the largest clone, αNKA1 , and the deduced amino-acid sequence are shown in Fig. 1b. It contains 254 bases of 5'-untranslated sequence, a 3,063-base open reading frame and 340 bases of 3'-untranslated sequence. An additional 10 bases of 5'-untranslated sequence were determined from clone αNKA2 and are included in Fig. 1b. The 3'-untranslated region contains the canonical polyadenylation signal²⁰ 23 bases upstream from the poly(A) tract. The position of the poly(A) tract was confirmed by sequencing the 3' end of αNKA3 , which contains a 14-residue poly(A) tract in this position rather than the three A residues seen in αNKA1 .

A striking feature of the 5'-untranslated region is the G + C-richness (72%) with an abundance of CpG dinucleotides, which are under-represented in the vertebrate genome as a

Fig. 1 Sheep kidney ($\text{Na}^+ + \text{K}^+$)ATPase α -subunit cDNA. **a**, Restriction map of clone pNKA1 and sequencing strategy. Only the restriction sites (P, *Pst*I; A, *Aua*I; Xh, *Xho*I; S, *Sall*; E, *Eco*RI; Xb, *Xba*I; B1, *Bgl*I; B, *Bam*HI; N, *Nco*I; BII, *Bgl*II) relevant to the sequencing strategy are shown. The extent and direction of sequencing are indicated by arrows (lower arrows, coding strand; upper arrows, noncoding strand). Hatched areas represent the 5'- and 3'-untranslated regions. **b**, Nucleotide sequence of clone pNKA1 and deduced amino-acid sequence. The first 10 nucleotides at the 5' end were determined from clone pNKA2 which extended slightly beyond the 5' end of pNKA1. Amino acids are numbered starting at the N-terminal Gly of the mature protein and are preceded by five amino acids occurring in the primary translation product. The eight major hydrophobic regions (H1-H8) are underlined. Brackets indicate the putative phosphorylation site (P), centred around Asp 369, and a portion of the ATP-binding site region (A), which includes Lys 501.

Methods. Poly(A)⁺RNA was isolated^{46,47} from sheep kidney. cDNA was synthesized by the procedure of Gubler and Hoffman⁴⁸, size-selected by electrophoresis in agarose and capture of the 2,100–4,500-base-pair fraction on NA45 paper (Schleicher & Schuell), tailed with dCTP and annealed⁴⁹ with G-tailed *Pst*I-cut pBR322. *E. coli* RRI cells were transformed with 60 ng of cDNA and grown on agar plates containing tetracycline. Colonies were transferred to nitrocellulose master filters which were used to prepare two replicas⁵⁰ on Zeta Bind membranes (AMF Cuno). Following additional growth on tetracycline and amplification on chloramphenicol, the filters were processed by the procedure of Geyer and Johnson⁵¹. Filters were hybridized successively with two oligonucleotide probes (see text for composition of probes) which were 5' end labelled using *T*₄ polynucleotide kinase and [γ -³²P]ATP. Conditions for hybridization, washing and autoradiography were basically as described by Boyd *et al.*⁵². DNA sequencing was performed by the chemical cleavage method of Maxam and Gilbert⁵³. Restriction fragments were labelled either at the 5' end using [γ -³²P]ATP and *T*₄ polynucleotide kinase, or at the 3' end using the Klenow fragment of DNA polymerase I and [α -³²P]dNTPs.

whole²¹. The phenomenon of CpG suppression is attributed to the effects of methylation and subsequent mutation that causes a decrease in CpG content and a corresponding increase in the number of TpG and CpA dinucleotides²¹. In the case of the ($\text{Na}^+ + \text{K}^+$)ATPase mRNA, there is no apparent CpG suppression in the 5'-untranslated region; the CpG content is 90% of the value expected based on nucleotide composition, whereas the TpG+CpA content is 87% of the expected value. However,

CpG suppression is apparent in the coding region, where the CpG content was 46% of the expected value against 135% for TpG+CpA. Recent evidence suggests that G+C-richness may be a common feature of the 5' regions of housekeeping genes^{22,23} and the present results support that view. As suggested by Bird²⁴, it may be useful to consider an evolutionary perspective when assessing the significance of these G+C-rich tracts. As these regions have escaped CpG suppression their functional role

Fig. 2 Comparison of the amino-acid homology and hydropathy plots of the sheep kidney ($\text{Na}^+ + \text{K}^+$)ATPase α -subunit and the rabbit cardiac Ca^{2+} -ATPase. **a**, Amino-acid homology between the ($\text{Na}^+ + \text{K}^+$)ATPase (NKA) and the Ca^{2+} -ATPase (CA). The sequences compared are those with $>30\%$ homology. Homologous residues are indicated by an asterisk; gaps have been included to maximize homology. **b**, Hydropathy plots of the ($\text{Na}^+ + \text{K}^+$)ATPase (top panel) and Ca^{2+} -ATPase (bottom panel). Hydrophobic regions are above the x axis and hydrophilic regions below it. The parallellograms indicate the regions of homology shown in **a** and their relative positions along the peptide chains. The phosphorylation site is indicated by P and the ATP binding site by A. The numbers indicate the eight major hydrophobic regions of the ($\text{Na}^+ + \text{K}^+$)ATPase. Homology comparisons and hydropathy analyses were performed using the International Biotechnologies sequence analysis programs. The hydropathy program is based on the procedure of Kyte and Doolittle³¹.

may have little to do with methylation (which may be of recent evolutionary origin and confined to vertebrates²⁵) but instead could be part of an evolutionarily older regulatory process which operates in both vertebrates and invertebrates.

The identification of the translation initiation site is unambiguous as it is the first AUG codon; it is preceded by 264 bases of G+C-rich sequence and lies within the consensus sequence for initiation described by Kozak²⁶. The initiation methionine is located five amino acids upstream from the known N-terminal peptide of the protein¹⁹. Thus, the primary translation product does not contain a hydrophobic N-terminal signal peptide. Only a five-amino-acid sequence, Met-Gly-Lys-Gly-Val, is removed to yield the N-terminus of the mature protein, which has 1,016 amino acids and an M_r of 112,177. The C-terminal amino acids, Thr-Tyr-Tyr-COOH, are identical to those of the dog kidney enzyme²⁷.

Several considerations lead us to conclude that the Asp that is phosphorylated during the catalytic cycle²⁸ is at position 369. The most compelling evidence is its location within an extended region of homology with the phosphorylation site region of the Ca^{2+} -ATPase²⁹ (see below). Furthermore, the surrounding sequence, Cys-Ser-Asp-Lys (Fig. 1b), is consistent with that determined by Bastide *et al.*⁶ and lies within the region predicted on the basis of experiments using proteolytic digestion (reviewed in ref. 13). Several laboratories have identified a peptide containing a Lys residue which reacts with fluorescein isothiocyanate (FITC) and which forms a part of the ATP-binding site^{5,30}. This FITC peptide corresponds to residues 496–506 (Fig. 1b). The

reactive residue, Lys 501, is located 132 amino acids away from the phosphorylation site.

There are eight major hydrophobic sequences (H1–H8), ranging in size from 17 to 29 amino acids (see Figs 1b, 2b). Based on the hydropathy values of membrane-spanning segments analysed by Kyte and Doolittle³¹, it is likely that each traverses the membrane.

Homology with Ca^{2+} -ATPase

A comparison of the amino-acid sequence and hydropathy plot of the ($\text{Na}^+ + \text{K}^+$)ATPase α -subunit with those of the Ca^{2+} -ATPase³² is shown in Fig. 2. The overall structural organization of the ($\text{Na}^+ + \text{K}^+$)ATPase is strikingly similar to that of the Ca^{2+} -ATPase. The two proteins are virtually identical in size and in the location of their phosphorylation and ATP-binding sites and each of the eight large hydrophobic domains of the ($\text{Na}^+ + \text{K}^+$)ATPase has its counterpart in the Ca^{2+} -ATPase (Fig. 2b). Except for three regions where ≥ 20 amino acids seem to have been inserted into or deleted from one or the other protein, matching structural features occur throughout the peptide chains. These proteins have clearly evolved from a common ancestor.

Several major regions of amino-acid homology (Fig. 2a) are located between H2 and H3 and between H4 and H5. Experimental evidence, both for the ($\text{Na}^+ + \text{K}^+$)ATPase³³ and for the Ca^{2+} -ATPase¹⁵, suggests that these areas are on the cytoplasmic side of the membrane. The greatest homology is near the phosphorylation site. A 10-amino-acid sequence which includes Asn

Fig. 3 Comparison of the N-terminal amino-acid sequences of the $(\text{Na}^+ + \text{K}^+)\text{ATPase}$ α -subunit of several species. Identical residues are boxed. Duck salt gland data from ref. 35; dog kidney data from ref. 34; brine shrimp data from ref. 36.

369, is identical in the two proteins. The homology ends abruptly at Met 384, where the hydropathy values become hydrophilic for the $(\text{Na}^+ + \text{K}^+)\text{ATPase}$ but are somewhat hydrophobic for the $\text{Ca}^{2+}\text{-ATPase}$. An insertion or deletion may have occurred here because the $(\text{Na}^+ + \text{K}^+)\text{ATPase}$ has 32 fewer amino acids between the phosphorylation site and the ATP-binding site. There is only a small region of homology at the ATP-binding site but several longer regions of homology occur nearer the C-terminus, including an interesting hydrophilic domain at residues 807–844. If H5 and H6 span the membrane, this sequence of the $(\text{Na}^+ + \text{K}^+)\text{ATPase}$ would be on the exterior of the cell, whereas for the $\text{Ca}^{2+}\text{-ATPase}$ it would be inside the sarcoplasmic reticulum.

There is no clear evidence regarding the location of the C-terminus for either the $(\text{Na}^+ + \text{K}^+)\text{ATPase}$ or the $\text{Ca}^{2+}\text{-ATPase}$. However, as the last 20 amino acids of the $(\text{Na}^+ + \text{K}^+)\text{ATPase}$ are fairly hydrophilic it is more likely to be located on the cytoplasmic side of the membrane. Also, a cytoplasmic location would be necessary if all four hydrophobic domains in the C-terminal half of the protein span the membrane. The hydropathy values³¹ of these segments and the corresponding segments of the $\text{Ca}^{2+}\text{-ATPase}$ suggest that this is the case.

N-terminal domains

The N-terminal region of the $(\text{Na}^+ + \text{K}^+)\text{ATPase}$ is strongly hydrophilic and does not have a homologous counterpart in the $\text{Ca}^{2+}\text{-ATPase}$. If the first major hydrophobic domains of the two proteins are aligned it seems that the $(\text{Na}^+ + \text{K}^+)\text{ATPase}$ has ~35 additional amino acids at its N-terminus (see Fig. 2b). Figure 3 shows a comparison of the N-terminal sequences of mammalian, avian and crustacean $(\text{Na}^+ + \text{K}^+)\text{ATPase}$ α -subunits. The similarity between the sheep and dog kidney

enzymes³⁴ and that of the duck nasal salt gland³⁵ was noted previously but the crustacean (brine shrimp) sequences were thought to be very different³⁶. However, we find that this is not the case. Although the first 14 amino acids in the sheep enzyme are absent from the brine shrimp enzyme, there is considerable homology beyond that point, particularly the conservation of several lysine residues. The brine shrimp isoform that most closely resembles the sheep enzyme has 9 lysines among the first 26 amino acids³⁶. Eight of these residues are present in the sheep enzyme; an Arg is present at the remaining position. This is quite striking because the evolutionary divergence of these two species occurred over 400 Myr ago.

Several lines of evidence suggest that this region influences the cation-dependent equilibrium between the E1 and E2 conformational states³³. A conformation-dependent trypsin site ~20 amino acids from the N-terminus is cleaved rapidly in 10 mM NaCl, yielding an N-terminal Ala, but is inaccessible in KCl^{27,33}. The small fragment removed contains a histidine which may be involved in the cation-effect on the E1–E2 equilibrium^{33,37}. This trypsin site could be at Lys 18, as it is followed by an Ala and preceded by a His at position 13. The brine shrimp enzyme, which is exposed to a very different salt environment from that of mammals and birds, lacks the short sequence that contains His 13. An interesting possibility is that the N-terminal hydrophilic domain, which contains many charged residues including the highly conserved Lys residues (Fig. 3), controls the passage of Na^+ and K^+ ions to and from cation-binding sites on the cytoplasmic side of the protein. This possibility is consistent with the lack of homology in this region between the $(\text{Na}^+ + \text{K}^+)\text{ATPase}$ and the $\text{Ca}^{2+}\text{-ATPase}$.

The N-terminus of the $(\text{Na}^+ + \text{K}^+)\text{ATPase}$ ³⁸, like the $\text{Ca}^{2+}\text{-ATPase}$ ³⁹, is located on the cytoplasmic side of the membrane. As the region between H2 and H3 is also cytoplasmic, H1 and H2 probably span the membrane and the hydrophilic junction between them should be located on the extracellular side of the membrane. It has been suggested that transmembrane sequences in this region form part of an ion channel³³. The presence of several acidic residues between H1 and H2, which could serve as cation-binding sites on the extracellular surface, is consistent with this possibility. Also, Ca^{2+} -ionophore activity has been demonstrated for the corresponding region of the $\text{Ca}^{2+}\text{-ATPase}$ ⁴⁰.

Energy transduction region

One of the most interesting sections of the $(\text{Na}^+ + \text{K}^+)\text{ATPase}$ is the region which contains the phosphorylation site and hydrophobic domains H3 and H4 (Fig. 2b). A proteolytic fragment

Fig. 4 Energy transduction region and ouabain binding site. **a**, Comparison of the amino-acid sequence of $(\text{Na}^+ + \text{K}^+)\text{ATPase}$ (NKA) with the corresponding sequences of the $\text{Ca}^{2+}\text{-ATPase}$ (CA) and the $\text{K}^+\text{-ATPase}$ B protein (KA) of *E. coli*¹⁸. The sequences compared extend from Ile 305 of the $(\text{Na}^+ + \text{K}^+)\text{ATPase}$, which is on the N-terminal side of H4, to Thr 375 which is six residues to the C-terminal side of Asp 369, the phosphorylation site (indicated by the asterisk). Identical residues are boxed. **b**, Comparison of the hydropathy plots for the $(\text{Na}^+ + \text{K}^+)\text{ATPase}$ (top panel) extending from Glu 280 to Thr 375, which includes H3 and H4 and the phosphorylation site, indicated by the asterisk, with those of the corresponding region for the $\text{Ca}^{2+}\text{-ATPase}$ (middle panel) and the $\text{K}^+\text{-ATPase}$ B protein of *E. coli* (bottom panel). The probable location of the ouabain binding site is indicated. The hydropathy plots are not condensed as in Fig. 2b; nine residue averages for each amino acid have been plotted³¹.

that maps to this region contains membrane-embedded sequences and includes both the phosphorylation site and a site which reacts with a ouabain photoaffinity derivative³⁸. The accessibility of trypsin and chymotrypsin sites at the N-terminal boundary of this peptide, and a trypsin site at the C-terminal boundary, are dependent on the conformation of the enzyme (reviewed in ref. 33). Possible locations of these proteolytic sites are, respectively: Arg 262, which would yield the expected N-terminal isoleucine²⁷; Phe 284, the first residue of H3; and Arg 423, which would yield the expected N-terminal Ala²⁷.

A region located between the trypsin sites was compared with similar sequences of the Ca^{2+} -ATPase and the K^{+} -ATPase B protein of *Escherichia coli*¹⁸. When the full hydropathic plot for the K^{+} -ATPase B protein was compared with that of the $(\text{Na}^{+} + \text{K}^{+})$ -ATPase (data not shown), the only major hydrophobic domains which seemed to be analogous were those next to the phosphorylation site. Furthermore, there was a region of amino-acid homology around the phosphorylation site that extended into H4. This is of interest because H4 is the only major hydrophobic domain that exhibits strong amino-acid homology between the $(\text{Na}^{+} + \text{K}^{+})$ -ATPase and the Ca^{2+} -ATPase, and because of its proximity to the phosphorylation site it would be a likely pathway for transmitting conformational changes into the intramembrane regions of the protein. The amino-acid homology for this section of all three enzymes is shown in Fig. 4a and the hydropathy plots for sequences including H3 and extending through the phosphorylation site are shown in Fig. 4b. The similarity in their hydropathy plots and the amino-acid homology between these eukaryotic and prokaryotic ATPases suggests that the sequence extending from the phosphorylation site into H4 may be an energy transduction pathway⁴¹ into the transmembrane domains involved in cation transport.

Cardiac glycoside binding site

An attractive possibility for the location of the ouabain binding site is the junction between H3 and H4. Studies with anthroyl-ouabain indicate that the binding site is relatively hydrophobic, shielded from water and is close to a Trp residue⁴². This observation prompted the development of a ouabain photoaffinity derivative which is activated by energy transfer from an excited Trp residue; this derivative was incorporated exclusively into the N-terminal half of the protein⁴³. Similar results were obtained with an alkylating-ouabain derivative⁴⁴. The ouabain binding site in this portion of the molecule seems to be localized to the H3-H4 region, but binding has also been demonstrated in the C-terminal region³⁸. It has been suggested that this additional site, which could be at the H5-H6 junction or the H7-H8 junction, is not specific for the steroid-like portion

of the molecule⁴³.

If the path of the polypeptide chain through the membrane is as suggested here, then there are just four short extracellular sequences. Only the H3-H4 junction, which includes residues 307-312 and probably some adjacent residues, seems to have all the properties predicted for the ouabain binding site. First, it is relatively hydrophobic yet should not be embedded in the membrane as it contains two glutamate residues, a Trp and a Tyr. Trp and Tyr, although hydrophobic in some respects, are infrequently buried⁴⁵. Second, the presence of a Trp is expected based on the studies described above and Trp 310 is the only such residue found in the probable extracellular regions of the protein. Third, this site is not homologous with the corresponding region of the Ca^{2+} -ATPase, which does not interact with cardiac glycosides. Fourth, given the inhibitory effects of cardiac glycosides on enzyme activity⁷, this site is ideally situated with respect to the proposed energy transduction region and phosphorylation site.

Conclusions

The probable structure of the catalytic subunit of the $(\text{Na}^{+} + \text{K}^{+})$ -ATPase, deduced from the present work and the studies discussed above, is as follows. The protein consists of 1,016 amino acids and has eight transmembrane domains. Much of the protein, including the hydrophilic N-terminal domain, the sequences between H2 and H3 and those between H4 and H5, is located on the cytoplasmic side of the membrane. The C-terminus and the region between H6 and H7 are also likely to be cytoplasmic. Very little of the protein is extracellular.

As well as the phosphorylation site and the ATP-binding site, several possible functional domains have been identified. The hydrophilic N-terminal domain might function on the cytoplasmic side as an ion-selective barrier which controls access to cation-binding sites. Hydrophobic domains H1 and H2 may form part of a cation channel and the hydrophilic junction between them is a likely candidate for extracellular cation-binding sites. A relatively hydrophobic extracellular cleft between H3 and H4 has the characteristics expected for the digitalis binding site and is connected to the phosphorylation site by a sequence which may be an important component of the energy transduction system.

We thank David MacLennan for stimulating discussions and for providing the Ca^{2+} -ATPase sequences before publication, Jeannette Greeb for technical assistance and Anil Menon for help with the computer analyses. We also thank Earl Wallick, James Ball, Lois Lane and Terry Kirley for useful suggestions and Gwen Kraft for preparing the illustrations. This work was supported by NIH grants HL 28573 and HL 22619 (mission ID).

We have cloned and sequenced complementary DNA encoding a Ca^{2+} -ATPase of rabbit muscle sarcoplasmic reticulum. We propose a model of the protein which has 3 cytoplasmic domains joined to a set of 10 transmembrane helices by a narrow, penta-helical stalk. In this model, ATP bound to one cytoplasmic domain would phosphorylate an aspartate in an adjoining cytoplasmic domain, inducing translocation of Ca^{2+} from binding sites on the stalk.

THE $\text{Ca}^{2+} + \text{Mg}^{2+}$ -dependent ATPase (Ca^{2+} -ATPase) of rabbit skeletal muscle sarcoplasmic reticulum, first isolated in 1970 (ref. 1), is a mammalian ion-transport enzyme which has been extensively investigated at the molecular level². The membrane-bound enzyme is cleaved instantly by trypsin (at site T_1) into two fragments of equal length, A and B; fragment A is cleaved more slowly (at site T_2) into unequal subfragments A_2 and A_1 (ref. 3). Functional sites have been associated with these fragments, each of which is independently anchored in the membrane². More detailed information on the topography of the enzyme and on the localization of active sites has been obtained from the amino-acid sequence of five cytoplasmic segments of the enzyme which include the amino-terminus (sequence 1), the

carboxy-terminus (sequence 5) and three long, internal segments (sequences 2–4)⁴. Hydrophobic transmembrane sequences have not been obtained, however, leaving a gap in our understanding of the structures through which Ca^{2+} ions are bound and transported across the membrane.

The need to obtain the full sequence of the Ca^{2+} transport enzyme, together with the desirability of obtaining new information about genes for homologous proteins and the expression of these genes during development, has led us to clone complementary DNA encoding two forms of the Ca^{2+} -ATPase. The characterization of one of these cDNA clones has permitted us to determine its complete primary structure and to predict its secondary and tertiary structure.

Fig. 1a. Sequencing strategy for cloned cDNA encoding a Ca^{2+} -ATPase protein of rabbit muscle sarcoplasmic reticulum. The restriction map displays six-base restriction endonuclease sites and those four-base restriction sites that were used in sequencing. The coding region is divided into three segments, A_2 , A_1 and B, which correspond to the A and B fragments generated by brief tryptic digestion of the fast twitch skeletal ATPase protein in intact sarcoplasmic reticulum³. **b.** Nucleotide and deduced amino-acid sequence of the Ca^{2+} -ATPase. The amino-acid sequence of the clone bears 84% identity with the fast skeletal ATPase⁴ and identity with a sequence of 17 amino-acid residues ((R)TSMKMFVKGAPEGVIDR beginning at residue 505) found in the Ca^{2+} -ATPase from canine cardiac sarcoplasmic reticulum (Briggs, F. N. *et al.*, in preparation). Nucleotide residues are numbered positively in the 5' to 3' orientation beginning with residue 1 of the ATG codon for the initiator methionine and ending with the last residue before the poly(dA) tail. They are numbered negatively beginning from the 5' side of residue 1 to the beginning of the poly(dG) tail (added to the 5' end of the cDNA before its incorporation into the vector pcD-X³⁶). The deduced amino-acid sequence is shown below the nucleotide sequence. Amino-acid residues are numbered beginning with the initiator methionine below the residues on the left-hand of each row. Polar segments, of sufficient length to be transmembrane, are underlined. Extensions of transmembrane segments and potential transmembrane segments (see Fig. 2) are underlined with a broken line. The major tryptic sites (T_2 and T_1), the sites of phosphorylation (P) and the site of FITC binding (F) are indicated beneath the appropriate amino acids.

Methods. Total RNA was extracted from skeletal muscle of 1–3-day-old rabbits as described previously³⁷, with the following modifications. SDS and diethyl pyrocarbonate were absent from all solutions and RNA was extracted with CHCl_3 /isoamyl alcohol (4:1) before a single step of chromatography on an oligo(dT)-Sepharose column. A series of cDNA libraries was constructed in the vector pBR322 by standard procedures involving first-strand synthesis by reverse transcription of oligo(dT)-primed mRNA, second-strand synthesis with the Klenow fragment of DNA polymerase, removal of the hairpin loop with S_1 nuclease, tailing with deoxycytidine and ligation of the double-stranded cDNA with Pst I-cleaved, oligo(dG)-tailed pBR322. The first library of 3,500 clones was probed with a group of four synthetic oligomeric deoxynucleotides of composition 5'-GC^ATACAT^GAACCA-3 based on the amino-acid sequence (W)FMYA recently determined for a hydrophobic peptide in the B fragment of the Ca^{2+} -ATPase³⁸. This screening yielded the first fast skeletal muscle ATPase clone, pFA1, containing 75 bp of coding sequence lying within a 234-bp Pvu II/ Pvu II fragment near the 3' end of the fast skeletal muscle ATPase clone (the homologous Pvu II/ Pvu II fragment is present in the clone described in Fig. 1). A fragment of 71 bp was cut from pFA1 with Sau 3a and Hae III and used to probe a second library of 50,000 clones yielding six clones of fast skeletal ATPase and two cross-hybridizing clones, pCA1 (1,900 bp) and pCA2, which contained all of the residues in pCA1 but terminated earlier in the 3'-untranslated region. These clones were sequenced and the 234-bp Pvu II/ Pvu II fragments from both groups of clones were used to probe a library of 1.6×10^6 clones in the vector pcD-X using the method of Okayama and Berg³⁹. This library yielded 3 fast skeletal muscle clones and 16 cross-hybridizing clones. The longest cross-hybridizing clone, pCA3 (3,722 bp), was restriction-mapped as illustrated above and clones pCA3 and pCA4 (3,602 bp) were used for sequence analysis. Restriction endonuclease fragments were subcloned into the vectors pEMBL8 and pEMBL9 to obtain sequences in both orientations³⁹. Sequences initiated at sites other than restriction sites were obtained from the shorter clones that terminated in regions inaccessible by suitable restriction endonuclease fragmentation. Production of single-stranded DNA suitable for DNA sequencing was induced by superinfection with the phage IR1 (ref. 20). Single-stranded DNA was sequenced by the dideoxy method of Sanger *et al.*⁴⁰

initiator Met codons in the first 128 nucleotides upstream of the ATG in our ATPase transcript suggests that this region is untranslated, consistent with our earlier observations¹¹ that the fast skeletal muscle Ca^{2+} -ATPase is synthesized without an amino-terminal signal sequence.

We do not yet know whether the 128 nucleotides upstream of the first Met codon represent all, or only part, of the 5'-untranslated region of the ATPase transcript. Northern blot analysis of neonatal rabbit muscle messenger RNAs with our cDNA probes showed a hybridizable transcript of ~3.7 kilobases, suggesting that the cDNA clones are very close to full length. The 5'-untranslated sequence contained 65 G, 44 C, 16 A and 3 T residues. Thus, the nucleotide content of this sequence resembled the 5'-untranslated region of the $(\text{Na}^+ + \text{K}^+)$ ATPase gene transcript published elsewhere in this issue¹², but was even more G+C-rich (85%).

The 3'-untranslated region terminated in a poly(dA) tail. The sequence upstream of the tail did not contain a perfect AATAAA polyadenylation signal¹³, but the sequence AATACAA terminated 21 bases before the poly(dA) tail and was followed closely by the sequence TGTGATGC, which is very similar to the consensus sequence YGTGTTY found between many polyadenylation signals and their poly(A) tails¹⁴.

A sequence beginning 51 bases downstream of the stop codon (nucleotides 3,045–3,074) contained an interesting homology with the core sequence of the murine IgG enhancer sequence, although loop-outs would be necessary in order to achieve maximal homology. Our sequence GTGCGTTTTAGCAACACACCTGCCAGCCC (nucleotides 3,045–3,074) resembled the sequence GTGGTTTGAACACTCTGTCAGCCC reported by Hayday *et al.*¹⁵ as comprising part of an enhancer sequence.

Homology between ATPases

Homology between the amino-acid sequences of the extramembranous segments of the Ca^{2+} -ATPase and the K^+ -ATPase of *Escherichia coli* has already been pointed out¹⁶. There was ~50% homology in some limited regions covering a total of ~180 residues. Note that there is little or no homology in the

transmembrane regions beyond a general hydrophobicity, but that the location of these hydrophobic sequences in the overall sequence is very similar in the two ATPases. The regions of homology with the $(\text{Na}^+ + \text{K}^+)$ ATPase¹² were more extensive and included the transmembrane segments M_4 , M_6 and M_7 (see Fig. 2). The first transmembrane segment, M_1 , is interesting in that both Ca^{2+} and $(\text{Na}^+ + \text{K}^+)$ ATPase sequences showed separate homologies with the M_1 section of the K^+ -ATPase while showing little resemblance to each other.

Secondary and tertiary structure

In the absence of a database of membrane proteins of known structure, empirical prediction of their secondary structure is unreliable¹⁷ as strongly hydrophobic segments are almost invariably predicted as β -strands. Therefore, we have identified the

Fig. 2 Polarity profile and secondary structure analysis of the Ca^{2+} -ATPase aligned with the tryptic fragments and the previously determined major sequences of the fast skeletal muscle ATPase. The top line ('fragment') represents tryptic fragments (A_2 , A_1 and B) of the fast skeletal muscle ATPase⁴. The second line ('sequence') indicates previously determined major sequences of the fast skeletal muscle ATPase⁴, showing phosphorylation and fluorescein-reactive sites. The polarity index of amino-acid triplets is shown below these two lines (only polar residues score: S, T=1; N, Q, H=2; D, E, K=3; R=4). The plot is designed to emphasize polar interruptions of potential transmembrane helices. In a small helical bundle any polar interruption of >2 residues is likely to force at least one polar residue out into the hydrophobic lipid phase. For this reason, penalty points are added to the triplet score equal to the lowest score of the two outer residues. Any run of 21 residues rising nowhere above polarity 3 is a putative transmembrane sequence. Individual polar residues within putative transmembrane stretches are shown, facilitating evaluation of their influence. Other individually noted residues are charged residues in the α -helices that link the globular domains to the membrane, and tryptophans (changes in tryptophan fluorescence have been used to monitor conformational changes in the reaction cycle). We note that 11 out of 13 residues are located in transmembrane segments). Secondary structure is identified by the template fitting procedure of Taylor and Thornton¹⁹ and applied to long extramembranous segments: $\blacksquare$, Amphipathic helix; --- , β -strand; --- , hydrophobic transmembrane helix. The nomenclature for structural domains is shown at the bottom of the figure. The transmembrane domain consists of hydrophobic helices M_1 – M_{10} ; the stalk of amphipathic connecting helices S_1 – S_5 ; the transduction domain of residues 133–238 (antiparallel β -sheet); the phosphorylation domain of residues 330–505 (parallel β -sheet); the nucleotide-binding domain of residues 506–680 (parallel β -sheet); and the α -helical sub-domain of residues 681–740.

transmembrane sequences by their hydrophobicity and applied standard methods only to the extramembraneous regions. These regions of the ATPase are mainly on the cytoplasmic side of the membrane⁴ and are separated by transmembrane hydrophobic hairpins, which we have located by the polarity plot shown in Fig. 2. This plot gives results similar to those provided by the method of Kyte and Doolittle¹⁸ but has the advantage of indicating explicitly the nature and location of polar interruptions. Combination of this information with an α -helical net facilitated analytical evaluation of potential transmembrane segments.

An earlier analysis of secondary structure⁴ detected several regions of predominant β -sheet and α -helix and one section of α/β alternation which was tentatively identified as a nucleotide-binding site⁹. Clear evaluation was prevented by the uncertain priorities when α and β were predicted simultaneously, and by the incomplete sequence. Therefore, we used the improved procedure of Taylor and Thornton¹⁹ which starts from a prediction of α -helices, β -strands and β -turns and resolves some of the ambiguities in priority of strand and helix by comparing patterns of hydrophobicity and of supersecondary structure with known structures. Our general conclusions are shown in Fig. 2 and discussed below.

Various experiments have enabled functional sites to be assigned to the three tryptic fragments of the ATPase and their constituent sequences. Fragment A₂ has been implicated in Ca²⁺ binding and translocation²⁰⁻²³. The phosphorylation site²⁴ is near the amino-terminus of sequence 3 (see Fig. 2) and the nucleotide-binding site⁹ near the amino-terminus of fragment B. We have used these three sites as a basis for naming functional domains of the tertiary structure (Figs 2, 4). We have distinguished a fourth domain, the transduction domain, based on evidence that cleavage at the second tryptic site, T₂, prevents Ca²⁺ transport without inactivation of the ATPase²⁵. A similar site has been observed in the (Na + K)⁺ATPase²⁶.

Hydrophobic segments

The first pair of transmembrane segments (M₁ and M₂) are clearly defined by the high density of charged residues on either side of the hydrophobic segments. The next hydrophobic segment, M₂' (207-238), contains a typical β -bend sequence, SGTN, and, for this and other reasons (see below), it is unlikely to be transmembrane helix. A second pair of transmembrane segments (M₃ and M₄) is again clearly defined. From this point, at the beginning of the longest extramembraneous segment, there are no more nonpolar interruptions until residue 770. In earlier folding models of the ATPase^{2,4}, a transmembrane loop was arbitrarily introduced between amino-acid sequences 3 (residues 325-622) and 4 (637-759). We show here that this was unwarranted as these sequences are separated by only 15 relatively hydrophilic amino acids. These combined sequences create a polar cytoplasmic segment 450 residues long. The segment from residue 770 to the carboxy-terminus is largely hydrophobic and is broken only by three polar intrusions, each of ~20 residues. The first of the carboxy-terminal hydrophobic segments is long enough to pass twice across the membrane, creating transmembrane segments M₅ and M₆. There are four more possible transmembrane segments (M₇, M₈, M₉ and M₁₀), but two of these are either short or contain several polar residues (Fig. 2; hatched sections). There is a maximum of six crossings of the membrane in this carboxy-terminal region, but there may be as few as four. Our assignments predict that the polar connections on the luminal face, except for the connection between M₇ and M₈, will be short.

Extramembraneous domains

Before the first membrane hairpin (residues 1-59) there are three α -helices, the third of which (S₁) contains five aligned Glu residues and runs straight from the cytoplasm into the membrane (M₁) without any obvious bend (Fig. 3). The next cytoplasmic domain (residues 109-262) contains the second tryptic site (T₂). The central region (122-230) contains seven β -strands, seven

Fig. 3 Structure of the connecting stalk and attached transmembrane helices. This includes the probable Ca²⁺-binding domain region of the ATPase and part of the transmembrane channel. Note that the first three helices of the stalk are markedly amphipathic, with one highly charged face. There are 9 charges (5+, 4-) in this section of the transmembrane region, which increases to 21 (7+ and 14-) if the polar head-group regions are included. It is likely that the two high-affinity sites for Ca²⁺ are on the cytoplasmic face near the polar head groups, whereas the low-affinity sites involve a distinct set of Glu residues in the luminal head-group region.

ated by short loops, so that it is likely to fold to give an antiparallel β -sandwich²⁷. It is connected to the membrane by amino- and carboxy-terminal α -helices (S₂ and S₃), each of ~20 residues. If the segment M₂ were transmembranous it would deplete the domain of two β -strands, which would diminish its structural plausibility. It would also invert the topology of succeeding loops unless a further transmembrane segment were postulated (for example, by including the hydrophobic section of S₄). The homologous region of the (Na⁺ + K⁺) ATPase is more polar and seems not to have transmembrane sequence at this point¹². Therefore, we conclude that M₂' is part of the cytoplasmic domain.

The long cytoplasmic segment (residues 308-758) contains both the phosphorylation site and the nucleotide-binding site, separated by the tryptic cleavage site T₁. Most of this region (337-680) is predicted to consist of alternating β -strands and α -helices, which would fold to give parallel β -sheets²⁷. Both its size and the central tryptic cleavage site suggest that this region folds into two separate domains, the first of which is phosphorylated by a molecule of ATP bound to the second. In this respect, as well as in secondary structure, these domains resemble those of phosphoglycerate kinase and hexokinase²⁸. There is a further resemblance in that the second domain is followed by a short (60-residue) section of α -helices. In these proteins and in alcohol dehydrogenase such a helical addendum rejoins the first domain, giving a second interdomain link and establishing the hinge between the domains²⁸. These two parallel β -domains are typical of their class in that most of the β -strands are hydrophobic on both faces; this is particularly marked in the nucleotide domain. However, they lack the amino-terminal GXGXXG sequence characteristic of the nucleotide domain of many dehydrogenases and protein kinases²⁹.

Stalk region

The segments that connect the globular domains to the membrane are of particular interest as they are likely to include the Ca²⁺-binding region and to transmit movements from the phosphorylation and nucleotide domains that bring about ion translocation. There are five of these connecting segments if we

include the amino-terminus as a small additional domain. Because the connecting segments will form the narrow neck of the ATPase molecule, which can be seen in electron micrographs of negatively stained vesicles³⁰, we refer to them as stalk segments (S_1 – S_5). All but S_4 are strongly predicted to be helices of length ~ 3 nm. When the residues are written on an α -helical net (Fig. 4) the helices are clearly amphipathic, having a high density of charged residues on one face. The highly conserved segment S_4 , which connects M_4 to the phosphorylation site, is different in having a hydrophobic amino-terminus which gives priority to β -strand over α -helix. Nevertheless, a helix is likely to be favoured because of close association of the section with the other four helices of the stalk. Helices S_1 , S_2 and S_3 are notable for their 16 aligned Glu residues (Fig. 3) which must contribute to the Ca^{2+} -binding sites. With one aspartate, they are the only negatively charged groups adjoining the membrane in the A_2 fragment. There is no sequence there or elsewhere in the molecule which resembles the DXDXDX loop characteristic of the EF hand of Ca^{2+} regulatory proteins³¹. Five or six of these Glu residues will be in the lipid polar head group region on the cytoplasmic surface of the membrane, and four of these will be in the bend regions between the S and M helices (Fig. 3). On the luminal side of the M_1 – M_2 loop there is another cluster of four Glu residues (EEGEE), which is a strong candidate for the low-affinity sites from which Ca^{2+} is released into the lumen. We suggest that the low-affinity Ca^{2+} -binding sites on the luminal face are constituted from a completely different set of residues than the high-affinity sites.

Topography of ATPase domains

An outline of the structure of the Ca^{2+} -ATPase can be deduced from electron micrographs showing a globule attached to the membrane by a narrow stalk³⁰. The transmembrane helices are observed on freeze fracture as intramembranous particles³². In our planar diagram (Fig. 4) we suggest that the three extramembranous globular domains form a headpiece which lies on top of a stalk comprised of five helices which are, in turn, adjoined to five transmembrane helices. These transmembrane helices together with five additional helices at the carboxy-terminal end of the molecule, form the intramembranous basepiece.

Our knowledge of domain function, derived from extensive kinetic and labelling studies³³, suggests that all three extramembranous domains are highly interactive. The nucleotide domain is relatively independent of the rest of the molecule in that it can be blocked by FITC without preventing either phosphorylation from inorganic phosphate or Ca^{2+} transport energized by acetyl phosphate³⁴. Nevertheless, it is probably folded beside the other two globular domains, as it has to transfer the γ -phosphate of ATP to the phosphorylation site on the phosphorylation domain. There is also some interaction of this domain

Fig. 4 Assembly of ATPase domains. The predicted arrays of helices and the three major domains are laid out in a planar diagram. In the ATPase molecule the helices would form tight clusters. The ATP-binding domain would be folded beside the other two major domains, permitting interaction among all three and accounting for the approximately triangular molecular profile derived from electron micrographs of ordered arrays by optical diffraction⁴¹ and for the molecular shape deduced from hydrodynamic measurements³⁵ and electron microscopy³⁰.

with the Ca^{2+} -binding site as, for example, bound ATP accelerates the binding of Ca^{2+} , as well as influencing other stages of the reaction cycle³³. The planar diagram, while speculative, represents an advanced model for the secondary and tertiary structure of the Ca^{2+} -ATPase on which refinements and prediction of mechanism may eventually be based.

We thank Ms Stella de Leon for technical assistance; Mr Michael Shales and Mr P. B. Gillett for assistance in computer use; Drs M. Powers, P. Hwang and R. Fletterick for the gift of a cDNA library; Dr H. Okayama for assistance in the preparation of a full-length cDNA library; Dr J. Nilson for teaching us basic recombinant DNA technology; Drs M. Michalak, C. C. Liew and V. Watt for advice and aid in cloning and sequencing; Dr C. J. Ingles for his interest in this project; Dr W. R. Taylor for advice and assistance in analysis of secondary structure; Dr Gary Shull for information on the sequence of the $(\text{Na}^+ + \text{K}^+)\text{ATPase}$ before publication. † Laboratory of Chemoprevention, National Cancer Institute, Bethesda, Maryland 20205, USA

The partial amino-acid sequence of purified human transforming growth factor- β (TGF- β) was used to identify a series of cDNA clones encoding the protein. The cDNA sequence indicates that the 112-amino acid monomeric form of the natural TGF- β homodimer is derived proteolytically from a much longer precursor polypeptide which may be secreted. TGF- β messenger RNA is synthesized in various normal and transformed cells.

Two different peptides which can induce the reversible phenotypic transformation of mammalian cells in culture are termed transforming growth factor (TGF) α and β . TGF- α is synthesized by various transformed cell lines^{2,3} and competes with epidermal growth factor (EGF) for binding to the same cell-surface receptor². A 50-amino-acid-long TGF- α species has been purified and shown to share sequence homology with EGF⁴. This TGF- α is initially synthesized as part of a 160-amino-acid-long precursor molecule which undergoes NH₂- and C-terminal proteolytic processing to yield the mature peptide^{5,6}.

TGF- β has been isolated from tumour and normal cells and tissues⁷, including kidney⁸, placenta⁹ and blood platelets^{10,11}. The relatively high levels of TGF- β present in platelets, which also contain platelet-derived growth factor (PDGF), have led to the suggestion that TGF- β plays a role in wound healing¹². It is a homodimer of relative molecular mass (M_r) ~25,000 (ref. 11) which recognizes a cell surface receptor distinct from the EGF receptor^{13,14}. Treatment of NRK fibroblasts with TGF- β does, however, result in an increase in the number of membrane receptors for EGF¹⁵, which may explain the ability of TGF- β to greatly potentiate transforming activity of EGF and TGF- α on these cells⁷. Moreover, TGF- β alone can induce AKR-2B fibroblasts to form colonies in soft agar¹⁶. In addition to stimulating cell proliferation, TGF- β has recently been demonstrated to inhibit the anchorage-dependent growth of a variety of human cancer cell lines¹⁷. TGF- β may be identical or very similar to a growth inhibitor isolated from African green monkey (BSC-1) cells¹⁸ and has many properties in common with the tumour inhibitory factor TIF-1 (ref. 19). Whether TGF- β acts to stimulate or inhibit the growth of a particular cell type seems to depend on many variables, such as the physiological condition of the cell and the presence of additional growth factors.

Here we report the amino-acid sequence of human TGF- β determined from direct protein sequencing and cDNA cloning. The nucleotide sequence of the TGF- β cDNA reveals that the 112-amino-acid-long TGF- β monomer is initially synthesized as part of a precursor polypeptide. Northern hybridization analysis demonstrates that the TGF- β mRNA is present in normal cells and in many types of tumour cells.

Purification and sequence analysis

A purification scheme has been developed by Assoian *et al.*¹¹ which yields TGF- β from human blood platelets, a major site of TGF- β storage. This procedure was modified and used to obtain human TGF- β with a purity of >95% for subsequent sequence analysis (Fig. 1 legend). In agreement with previous work¹¹ the non-reduced TGF- β migrated as an M_r 25,000 protein in a SDS polyacrylamide gel, whereas reduction with β -mercaptoethanol converted it into an M_r 12,500 species. This

chains linked by intermolecular disulphide bridges. The purified TGF- β was reduced, alkylated and subjected to amino-terminal sequence analysis. The amino-acid sequences of several peptides obtained after clostripain digestion of TGF- β were also determined. These analyses yielded a 60-residue long contiguous sequence starting from the amino terminus (Fig. 1a) as well as several shorter peptide sequences (data not shown). The NH₂-terminus of the human TGF- β is identical to the previously determined NH₂-terminal sequence of bovine TGF- β ⁸. The fact that no heterogeneity was seen during the NH₂-terminal sequence analysis, and that all TGF- β sequences obtained could be accounted for by an M_r 12,500 polypeptide, provide additional evidence for the homodimeric nature of this protein.

Isolation of TGF- β cDNAs

The approach we followed for the identification of the nucleotide sequence encoding TGF- β was similar to the strategy used previously for TGF- α ³. Long oligonucleotides designed on the basis of the partial protein sequence were used as hybridization probes for the identification of a TGF- β exon in a human genomic DNA library, which was then used as a probe for the isolation of TGF- β cDNAs.

Two 44-mer deoxyoligonucleotides, β LP1 and β LP2, complementary to sequences encoding amino acids 3-17 and 30-44, respectively, were chemically synthesized (Fig. 1a). The choice of these nucleotide sequences was based on previously described considerations⁵. In addition, 16 14-mers were synthesized which are complementary to all possible codons for amino acids 13-16 (Fig. 1a). A human genomic DNA library²⁰ was screened under low stringency hybridization conditions using ³²P-labelled β LP1 as probe. One of the 58 hybridizing phage, β λ58, also hybridized with the 44-mer β LP2 and with the pool of 14-mers. Nucleotide sequence analysis of this clone revealed the presence of a TGF- β exon encoding amino acids 10-60 of TGF- β . Only about half of the sequence corresponding to the β BP1 oligonucleotide is present. Nevertheless, the probe hybridized because of the correct assignment of 23 of the 24 nucleotides in the portion of the probe corresponding to the exon sequence (data not shown).

To obtain the entire TGF- β coding sequence, this exon was used as a probe to screen a λ gt10-based cDNA library derived from human term placenta mRNA. The screening of ~750,000 oligo(dT) primed cDNA clones resulted in the isolation of one TGF- β cDNA (λ BC1) of ~1,050 base pairs (bp). The previously determined partial TGF- β sequence established the reading frame and revealed the sequence encoding the complete TGF- β polypeptide, followed by a stop codon 20 bp from the 3' end of the cDNA.

Northern hybridization^{21,22} using the λ BC1 cDNA insert as probe showed that TGF- β mRNA of ~2.5 kilobases (kb) is

lines. Extensive screening of cDNA libraries prepared from both these cell lines and of an additional placenta cDNA library yielded many different TGF- β cDNAs. Most of these seemed to contain sequence inversions generated during cDNA preparation ('Belgian' clones²³). In addition, single base deletions and substitutions were found in some of the cDNAs. Because of the high incidence of cDNA artifacts, presumably resulting from specific features in the mRNA or cDNA structure, all parts of the sequence were confirmed by sequencing at least two different cDNAs. Alignment of different cDNA sequences (Fig. 1b) enabled us to establish 2 kb of sequence preceding the TGF- β termination codon (Fig. 1c).

None of the 70 TGF- β cDNAs isolated from different oligo(dT)-primed cDNA libraries contained more than a few nucleotides of 3' untranslated sequences. As introns are rarely found in 3' noncoding regions, the 3' untranslated sequence was determined using cloned genomic DNA. DNA sequence analysis of phage β 58 revealed the presence of an exon encoding the carboxy-terminal part of TGF- β , followed by the stop codon and the 3' untranslated region (Fig. 1c). An AATAAA hexanucleotide sequence²⁴ was encountered 500 bp downstream from the termination codon, thus permitting an assignment of the putative polyadenylation site. The calculated size of TGF- β mRNA is in close agreement with the 2.5 kb length determined from the Northern hybridization experiments (Fig. 2).

Carboxy-terminus of TGF- β

The cDNA sequence establishes that TGF- β is synthesized as the C-terminal segment of a precursor polypeptide. As several proteins undergo post-translational removal of C-terminal sequences, we determined the actual C-terminal amino-acid sequence of TGF- β . The cDNA sequence predicted the presence of a single methionine near the C-terminus in TGF- β . The protein was reduced, alkylated and cleaved with cyanogen bromide (CNBr). Sequence analysis of the mixture of peptides resulting from the CNBr digestion revealed the C-terminal sequence predicted from the cDNA (data not shown), although it cannot be excluded that a fraction of the molecule had undergone C-terminal proteolysis.

Unmodified TGF- β was also treated with CNBr. Cleavage at the methionine residue resulted in the complete loss of biological activity, showing that at least part of this C-terminal octapeptide is needed for biological activity (data not shown).

mRNA in different cell types

The availability of a TGF- β cDNA allowed us to screen various cells for TGF- β mRNA (Fig. 2). TGF- β mRNA was detectable in all human tumour cell lines including Wilms Tumour, A172 (glioblastoma) and the carcinoma cell lines T24 (bladder carcinoma), A431 (Squamous epidermoid carcinoma), MCF-7 (mammary carcinoma) and KB (nasopharyngeal carcinoma). HT1080, a fibrosarcoma-derived cell line, which we had chosen as a source of mRNA for the cDNA cloning, contained relatively high levels of TGF- β mRNA. TGF- β mRNA was not only present in cell lines derived from solid tumours of meso-, endo- and ectoblastic origin, but was also detectable in tumour cell lines of hematopoietic origin, for example Daudi (Burkitt lymphoma B lymphoblast), Raji (Burkitt lymphoma B lymphoblast) and Molt-4 (T-cell leukaemia). The presence of TGF- β mRNA is not restricted to tumour cells, as it is clearly detectable in placenta and peripheral blood lymphocyte (PBL) mRNA. Strikingly, the level of TGF- β mRNA is significantly elevated after mitogenic stimulation of PBLs. TGF- β mRNA was not detectable in human liver, yet was present in the HEP-G2 hepatoma cell line. In all cases, the TGF- β mRNA migrated as a species with an apparent length of ~2.5 kb.

Discussion

Analysis of several overlapping cDNAs and gene fragments has led to the determination of a continuous sequence of 2,439 bp corresponding to the TGF- β precursor mRNA. An initiator ATG is located 842 nucleotides from the 5' end and establishes

Fig. 2 Northern hybridization of mRNA from different sources with a TGF- β cDNA as probe. The cell source of the polyadenylated RNA is shown above each lane. The following cell lines were used: the hepatoma HEP-G2, Wilms tumour TuWi, glioblastoma A172, bladder carcinoma T24, squamous epidermoid carcinoma A431, mammary carcinoma MCF-7, nasopharyngeal carcinoma KB, fibrosarcoma HT1080, Burkitt lymphoma B lymphoblasts Daudi and Raji and T lymphoblast Molt-4. The cells growing in the monolayer were collected at confluency. The peripheral blood lymphocytes were prepared and mitogen-induced with staphylococcal enterotoxin B and phorbol myristate as described previously⁵⁴. RNA was prepared 24 h after induction. Comparison with the position of the 28S and 18S ribosomal RNA on the gel suggests a length of ~2.5 kb for the TGF- β mRNA. 4 μ g of polyadenylated mRNA was electrophoresed into a formaldehyde 1.2% agarose gel²¹ and blotted onto nitrocellulose filters²². The ³²P-labelled⁵⁶ EcoRI cDNA insert of λ BC1 was used as a probe under high stringency conditions (see Fig. 1 legend).

a coding sequence of 1,173 nucleotides, thus encoding a 391 amino-acid long polypeptide (Fig. 1b, c). Several areas in the cDNA sequence have an exceptionally high G-C content. In particular, the first 450 bp at the 5'-terminus has regions with >80% G-C content. The location of these G-C rich regions coincides with the areas in which the many cDNA cloning artifacts occurred and where partial length cDNAs were obtained. It is likely that the first ATG triplet located at position 842 (Fig. 1c) is the initiation codon as it is preceded in the same reading frame by several stop codons and it could initiate translation into a continuous sequence of a large polypeptide which comprises the TGF- β monomer. However, the sequence context at this ATG is not in good agreement with the proposed initiation codon consensus sequence G/ACCATGG²⁵. Furthermore, this ATG is localized in a very G-C rich area. A second ATG, found in the same reading frame at position 954, is in much better agreement with the initiation codon consensus sequence and is localized within a 40-nucleotide region of relatively low G-C content (~50%). This ATG may be more accessible to the ribosome, especially as it is localized within a large G-C region. Although it is more likely that translation starts at the first ATG, it is conceivable that the second ATG could also be used to initiate translation of a smaller TGF- β precursor.

The 5' untranslated region of the TGF- β mRNA is at least 841 nucleotides long and contains a 61-nucleotide-long sequence (positions 192-252) consisting almost exclusively of purines. The biological relevance of the exceptionally long 5' untranslated region of high G-C content is unknown, but it is similar to the structural organization of the mRNAs for *c-myc*²⁶ and insulin-like growth factor-2 (ref. 27). However, there is no striking sequence homology between these sequences. The first 120 bp of the TGF- β cDNA can theoretically be folded into hairpin loop structures with a calculated stability of -92 kcal (data not shown). It is tempting to suggest that the long 5' untranslated sequence and these hairpin loop structures could play a role in mRNA stability or in the regulation of transcription.

The stop codon at residue 2,016 is immediately followed by a remarkable, G-C-rich sequence of 75 nucleotides (Fig. 1c). This sequence consists of multiple repeats of CCGCC and ends with GGGGGC. The peculiar nature of this sequence is probably responsible for the fact that the 3' untranslated end of the mRNA could not be cloned as a cDNA sequence, perhaps because of the inability of the *Escherichia coli* DNA polymerase I to use this sequence as a template for the second strand cDNA synthesis. Similar repeat sequences have been found in the promoter regions of the genes for human dihydrofolate reductase²⁸, human adenosine deaminase²⁹ and Herpesvirus thymidine kinase³⁰. In the latter case, McKnight *et al.*³⁰ have shown that these structural elements are important in transcription efficiency. In addition, it has been shown that the promoter specific transcriptional factor Sp1 binds to such sequences in the simian virus 40 early promoter region and in a related monkey promoter³¹. In all these cases the G-C rich repeats are followed closely by the Goldberg-Hogness TATA sequence. In the case of TGF- β , however, these sequences are located in the 3' untranslated region of the gene, but, interestingly, are also followed by a TATA-like sequence. The hexanucleotide AATAAA, ~500 nucleotides downstream from the stop codon, probably functions as the TGF- β polyadenylation signal as this would agree with the size of TGF- β mRNA estimated from Northern hybridizations. Benoist *et al.*³² have proposed a consensus sequence TTCCTGCG which immediately precedes the poly(A) tail. A similar sequence, TTCAGGCC, follows the AATAAA sequence in the TGF- β mRNA, providing further support for the assignment of the polyadenylation site at position 2,539 (Fig. 1c).

The TGF- β cDNA encodes a polypeptide of 391 amino acids, assuming that the first ATG is used for translational initiation. Comparison with the experimentally determined NH₂-terminus of TGF- β shows that the C-terminal 112 amino acids constitute the TGF- β sequence. The TGF- β monomer is cleaved from the precursor at the Arg-Arg dipeptide immediately preceding the TGF- β NH₂-terminus. Similar proteolytic cleavage sites have been found in several other polypeptide precursor sequences^{33,34}. Determination of the hydrophobicity profile³⁵ predicts that this Arg-Arg sequence is located within a hydrophilic region which would make it accessible to a trypsin-like protease. Whereas cleavage of the precursor gives rise to the mature TGF- β monomer, it is not known if other biologically active peptides are also released. The TGF- β precursor contains several pairs of basic residues (Fig. 1c) which could also undergo post-translational cleavage and give rise to separate polypeptide entities. However, the TGF- β polypeptide itself contains two Arg-Lys dipeptides which apparently are not cleaved. The TGF- β precursor contains three potential N-glycosylation sites³⁶, none of which are localized within the TGF- β polypeptide (Fig. 1c).

The 112 amino-acid sequence of TGF- β contains nine cysteines, whereas the rest of the precursor contains only three (positions 33, 224 and 226; Fig. 1c). There are no data either on the location of the disulphide bridges or on which cysteines are involved in the interchain disulphide linkage of the TGF- β dimer. Previous studies have shown that reduction of the TGF- β dimer of *M*_r 25,000 generates a single band of *M*_r 12,500 on denaturing polyacrylamide gel¹¹. Sequence analysis of the TGF- β amino-terminus and of the TGF- β peptides obtained after clostripain digestion strongly suggest that the TGF- β dimer consists of two identical polypeptides. This homodimeric nature is also supported by the presence of only a single hybridizing DNA fragment on Southern hybridization of human genomic DNA with a TGF- β exon probe (data not shown). Chou-Fasman analysis of the secondary structure shows³⁷ that the TGF- β polypeptide contains extensive β -sheet with little α -helicity. The region immediately preceding the basic dipeptide cleavage site is probably α -helical.

TGF- β is stored in relatively large quantities in platelets and is also found in association with mammalian cells. It is also released into the culture medium of these cells and, therefore,

is probably a secreted protein. The deduced polypeptide sequence of the 391-amino-acid-long TGF- β precursor shows a contiguous sequence of 16 hydrophobic residues (positions 8-23, Fig. 1c). This sequence may constitute the hydrophobic core³⁸ of an NH₂-terminal signal peptide involved in protein secretion. It is not known at which residue this cleavage by the signal peptidase could occur, but comparison with other known signal peptides shows an average signal peptide length of 20-30 amino acids³⁸. The mature TGF- β would subsequently be released from the precursor as a result of the cleavage by a dibasic peptidase, localized at the external side of the membrane³⁹. Translational initiation at the second ATG (position 954) would result in a 354-amino-acid-long precursor devoid of the putative signal peptide.

Most growth factors seem to be made only by specific cell types. PDGF is present in or released by platelets, endothelial cells, smooth muscle cells and various tumour cells. TGF- α is made by tumour cells of non-haematopoietic origin but has not been demonstrated to be synthesized by any normal adult cells. Previous studies have shown that TGF- β can be found in kidney⁸, placenta⁹ and platelets^{10,11} and is released by several 'normal' and transformed fibroblast cell lines. We examined several types of normal and transformed cells from different embryonic origin for the synthesis of TGF- β mRNA. Our results show that all cell types except adult liver examined contain TGF- β mRNA. The amount of TGF- β mRNA seems to correlate with the degree of mitotic activity, which may explain our inability to detect TGF- β mRNA in adult liver tissue. Furthermore, TGF- β mRNA levels are higher in mitogen-induced lymphocytes than in unstimulated lymphocytes. This correlation also seems to hold for the higher levels of TGF- β expression in transformed cells compared with their non-transformed counterparts⁴⁰.

It is clear that much additional work is needed to elucidate the role of TGF- β during cell division and propagation and in the establishment and maintenance of the malignant phenotype. The knowledge of the structure of TGF- β and its precursor and the use of TGF- β cDNAs as molecular probes will certainly contribute to this understanding.

We thank Drs G. Nedwin, A. Ullrich, P. Seeburg and D. Capon for providing us with some cDNA libraries and mRNA samples, L. Rhee for help in DNA sequencing, L. Dart, N. Roche, D. Smith and J. Smith for assistance in the preparation of TGF- β and the Genentech DNA synthesis group for preparation of oligonucleotides. We also thank J. Arch for preparation of the manuscript.

Evidence for H α emission associated with the HI bridge connecting the Small and Large Magellanic Clouds

Michel Marcelin, Jacques Boulesteix & Yvon Georgelin

Observatoire de Marseille, 2 place Le Verrier,
13248 Marseille Cedex 04, France

The bridge of matter connecting the Small Magellanic Cloud (SMC) with the Large Magellanic Cloud (LMC) was first detected thanks to radio observations, and detailed maps of this HI bridge are now available¹. Observations of the Magellanic system at H α wavelength reported by Johnson *et al.*² in 1982 seem to show a diffuse H α emission associated with the HI bridge. As they suggested, it is necessary to confirm this association by obtaining H α profiles in the direction of this bridge. We did this in February 1984 with the help of a scanning Perot-Fabry interferometer and a photon-counting system at the 1.5-m European Space Observatory (ESO) telescope. The choice of the area to be observed was based on recent observations³ with the Very Wide Field Camera (VWFC) on board Spacelab 1 (November 1983) showing an extension of the SMC towards the LMC at wavelengths of 1,930 and 1,650 Å. Detection of H α emission would check that the ultraviolet emission was emanating from the bridge connecting the two galaxies by showing that the cloud of hot stars giving rise to this ultraviolet emission was ionizing part of the HI bridge.

The patchy diffuse area detected by Courtès *et al.* with the VWFC³ is $\sim 1^\circ \times 2^\circ$ in size. Courtès suggested that we should obtain profiles of the H α emission line where ultraviolet maxima had been found ($\alpha = 1$ h 50 min, $\delta = -74^\circ 17'$ and $\alpha = 2$ h 10 min, $\delta = -74^\circ 34'$).

The instrument used for our observations has been described elsewhere⁴. We used a simpler version of the CIGALE experiment at the 1.5-m ESO telescope. The focal reducer was a smaller one, which was operated manually and which reduced the f :15 aperture ratio of the telescope to f :2.7.

The field of view is ~ 7 arc min in diameter and a 5-cm diameter filter was used (this filter was centred at 6,567 Å with a full width at half maximum FWHM of 10 Å). The centre of the first selected field is at $\alpha = 1$ h 50 min and $\delta = -74^\circ 17'$ and falls on chart 58 V of the Hodge and Wright⁵ photographic atlas of the SMC, approximately between reference points WG 5 and L114. The scanning Perot-Fabry interferometer used interference order 798 (at H α), giving 8.2 Å, or 376 km s⁻¹ for the free spectral range. The observed field has been scanned with 21 steps (each step, or channel, corresponding to a given spacing of the plates of the interferometer) ensuring complete coverage of the free spectral range. Figure 1 shows the real-time display of this observation on a TV monitor. Four channels are selected

(number 1, 6, 11 and 16, clockwise from the upper left corner) and displayed on a 256 times 256 pixel screen while the full data (photon addresses in a 512 times 512 pixel grid for each of the 21 successive channels) are recorded on a magnetic tape. Each channel was exposed for 20 s in each scanning cycle of 21×20 s = 420 s. Then the cycle was repeated 25 times. Thus the total exposure time was 500 s for each of the 21 channels, with the seeing conditions fairly well averaged for each channel over the total exposure by the scanning mode used. The analysis of the data shows that the brighter interference rings on Fig. 1 are due to geo-coronal H α emission (the innermost one on channel 1 of Fig. 1) and OH night-sky line at 6569 Å (the precise wavelength⁶ of which is $6,568.72 \pm 0.02$ Å). The faintest ring (the one closest to the centre in channel 11 of Fig. 1) is due to faint H α emission by the object observed in the ultraviolet by the VWFC on board Spacelab 1. The possibility that it is produced by any night-sky emission line has been ruled out because it was not detected on the second field which was observed during the same night ($\alpha = 2$ h 10 min, $\delta = -74^\circ 34'$) despite an exposure time three longer (but only unscanned this time). The H α emission line profile that has been detected is broader and fainter than those of the night-sky emissions. The width of the line is as much as 60 km s⁻¹ compared with ~ 20 km s⁻¹ for the geo-coronal H α and for OH (the resolution imposed by the Finesse of the Perot-Fabry interferometer). The detected emission is fairly uniform over all the observed field and we may estimate its intensity by comparison with the geo-coronal H α emission line. Comparing interference rings of same diameter for the two lines, we calculated the ratio of the number of counts and applied a small correction ($\sim 15\%$) to take into account the fact that each line is transmitted through the interference filter with a slightly different transmission factor, because of its narrow bandpass. As a result we found an average intensity ratio H α (object)/geo-coronal H α = 0.4 ± 0.1 . Similarly, we found OH(6,569 Å)/geo-coronal H α = 0.8 ± 0.1 . The problem with the intensity of the night-sky lines is that they are highly variable, depending on parameters such as the geographical location, date, the time of night, zenith angle, the phase of the solar cycle and so on. Noting the values given by Chamberlain⁷, (5-20 Rayleighs for the geo-coronal H α emission at the zenith) and if we consider 10 Rayleighs as a typical value, we conclude that the detected object had an intrinsic emission around 4 Rayleighs. Converting into more usual units this gives an intrinsic monochromatic brightness around 10^{-6} erg cm⁻² s⁻¹, sr⁻¹ or 10^{-9} J m⁻² s⁻¹ sr⁻¹. This result is in very good agreement with the Johnson *et al.*² observation of the SMC-LMC bridge; they found a maximum H α brightness around $2-5 \times 10^{-9}$ J m⁻¹ s⁻¹ sr⁻¹ in the bridge between the two clouds.

However, the most interesting result is the radial velocity measured from the Doppler shift of the H α emission of this object. Comparing the diameters of the observed interference rings with calibration rings produced by a H α lamp we first

Fig. 1 Real-time display of four scanning channels on a TV monitor (geometric distortions making the rings non circular are due to the monitor itself). Each channel has been exposed 500 s. 21 channels insured a complete coverage of the field (clockwise from upper left are channel 1, 6, 11 and 16). The brighter interference rings are due to geo-coronal H α emission (the innermost one on channel 1) and OH 6,569 Å night-sky line (the second one from centre on channel 1). The H α emission of the SMC-LMC bridge appears as a faint ring surrounding to two bright rings of airglow on channel 1. Then one can see the diameter of the interference rings increasing while the interferometer is scanning from channel 1 to 21. The H α emission of the bridge appears as a large faint ring together with a small central spot on channel 6, a small central ring on channel 11, and the second ring on channel 16 (where OH is the central ring). The bright circular edge on each image is due to the less selective transmission on the edge of the interference filter.

checked the wavelengths of the geo-coronal H α emission and the OH night-sky line. The wavelength accuracy found for both lines is better than 0.05 Å (2 km s⁻¹ in radial velocity). The precision, indicated by the dispersion of the measured points, is about the same. The diameters of the H α interference rings from the object indicate an heliocentric radial velocity of 160 km s⁻¹ ± 5 km s⁻¹ all over the observed field (note that the rough value given by us in Courtès *et al.*³ was underestimated). Our final result is in very good agreement with the average H I velocities found by McGee and Newton⁸ and by Mathewson (personal communication)⁹ in the same area. Furthermore, they generally found several components (3–4) with velocities ranging from 140 to 200 km s⁻¹ and halfwidths around 20 km s⁻¹, which is consistent with the broadening observed for the H α emission. In some cases, our profile also appears to contain multiple velocity components but the signal-to-noise ratio remains too low to allow individual ones to be distinguished with certainty for their separations are near our spectral resolution.

It is clear, from the Doppler shift, that we are observing H α emission associated with the H I bridge between the SMC and LMC and that the large cloud of hotstars observed in ultraviolet light by the VWFC on board Spacelab 1 ionizes this bridge.

We thank our engineer André Fort for helpful assistance during the observations, and our technician Patrice Joulié who designed the focal reducer.

The Sun's motion perpendicular to the galactic plane

John N. Bahcall* & Safi Bahcall†

* Institute for Advanced Study, and † Princeton High School, Princeton, New Jersey 08540, USA

The period and amplitude of the Sun's motion perpendicular to the galactic plane are important parameters in some explanations of the terrestrial mass extinctions and cratering records^{1–5}. Here we have calculated the range of periods and vertical excursions that are consistent with the distributions of tracer stars in the Galaxy and have also evaluated the probable phase jitter in the solar period. We find acceptable half-periods for the vertical oscillation that range from 26 to 37 Myr (including the range of periods that have been inferred from the terrestrial records on mass extinctions and on cratering), maximum heights above the plane from 49 to 93 pc, and an average phase jitter per half-period of the order of 6–9%. The largest uncertainty in all these calculations is caused by the unknown distribution of the unseen mass that must be postulated to explain the distribution of observed stars^{6–7}. For all the models we consider, the most recent passage of the Sun through the galactic plane occurred in the past 3 Myr provided only that the present position of the Sun is between 0 and 20 pc above the plane. We extend the argument of Thaddeus and Chanan⁸ to show that the apparent periodicity in the mass extinction and cratering records cannot be caused by a population of objects (observed or unobserved) that contributes a major fraction of the total mass density at the solar vicinity.

We have calculated the time, t , that it takes the Sun to reach a height, z , above the galactic plane from the formula:

$$t = \int_0^z \frac{dx}{2(E - \varphi(x))^{1/2}} \quad (1)$$

where E is the total energy per unit mass of the Sun's vertical

motion and ϕ is the potential energy per unit mass. The major uncertainty in evaluating equation (1) arises from the distribution of the unseen matter that is inferred to exist at the solar vicinity^{6,7}. We have bracketed the allowed solar motion by using the potential ϕ calculated for two extreme Galaxy models, labelled here as the ISM and the all-disk models. In the ISM model, the unseen material is squashed towards the galactic plane to the maximum extent allowed by the analysis of the distribution of F dwarfs and of K giants; the postulated distribution is similar to that observed for ordinary interstellar material (hence the name). In the all-disk model, the unseen material has the largest exponential scale height (0.7 kpc) above the plane that is consistent with the observed rotation velocity of the galaxy near the solar position. In the all disk model, all of the unobserved material near the Sun is by construction in a flattened disk; there is no appreciable amount of unobserved material in a spherical halo. We also consider a more conventional model, the proportional model, in which the distribution of unseen material with a given velocity dispersion is proportional to the distribution of observed material, with the same velocity dispersion, the constant of proportionality being independent of velocity dispersion. The proportional model has approximately equal amounts of unobserved and observed material. The particular parameters we use for these models are given in Table 5 of ref. 7, rows 1 (proportional model), 10 (ISM model), and 12 (all disk model). For all three models, the potential was derived by solving self-consistently the Poisson and the Vlasov equations with realistic models for the Galaxy (typically 15 observed components).

Table 1 shows our results for the calculated half-periods and maximum heights above the plane of the solar vertical motion. For each of the models, we also list the time since the Sun last passed through the galactic plane. The characteristics of the calculated solar motion depend on the vertical velocity, v_{present} , and height above the plane, z_{present} . We give results for the range of values that are consistent with the available observational results⁹⁻¹¹, that is $v_{\text{present}} = 6-8 \text{ km s}^{-1}$ and $z_{\text{present}} = 0-30 \text{ pc}$. The most likely values are considered to be 7 km s^{-1} and 4 pc , respectively, although some determinations^{12,13} suggest that the Sun is 20-30 pc above the plane. The Sun's position with respect to the galactic plane could be determined more accurately using modern surveys of H I and CO.

The half-periods we calculate are: $31.5 \pm 1 \text{ Myr}$ (proportional

Fig. 1 The potential divided by $2\pi G\rho(0)z^2$ shown for the three numerical models.

model), $26.5 \pm 1 \text{ Myr}$ (ISM model), and $36 \pm 1 \text{ Myr}$ (all-disk model). The uncertainty due to the assumed current velocity and height above the plane is small compared with the difference between the values calculated with different distributions of the unseen material. For the most likely current parameters of the solar motion, the maximum height above the plane reached by the Sun, z_{max} , is: 70 pc (proportional model), 58 pc (ISM model), and 81 pc (all-disk model). The time since the last passage through the galactic plane is $< 3 \text{ Myr}$ in all the cases considered, provided that the Sun's current position is between 0 and 20 pc above the plane. The potential energy is currently much less than the kinetic energy for the solar vertical motion, so that the time since last passage is approximately the present height above the plane divided by the current velocity.

The problem of the solar vertical motion has usually been treated analytically by assuming^{8,14} that the potential for the vertical motion is quadratic in the height above the plane. In this approximation, the vertical motion is described by the equation for a simple harmonic oscillator. We show in Fig. 1 the potential, divided by $2\pi G\rho(0)z^2$, that was computed numerically for each of the galactic models we have discussed. Significant departures from the harmonic approximation are present beyond about 40 pc. Innanen *et al.*¹⁵ have evaluated numerically the solar motion in a simple galaxy model that includes departures from harmonicity.

How much of an error does the conventional assumption of a harmonic oscillator potential cause? The harmonic oscillator period differs from the exact half-period by 15% (4 Myr) for the ISM model, by 9% (3 Myr) for the proportional model, and by 6% (2 Myr) for the all-disk model. The error in the maximum height above the plane implied by the harmonic oscillator potential is, for the same three cases, 11, 6 and 4%.

The harmonic oscillator approximation can be used with relatively small errors in the computation of the fractional amount of time the Sun spends in any specified height range, once the period and maximum height above the plane have been calculated from the exact potential. We have evaluated numerically the fraction of time that the Sun spends in various height intervals using the potentials shown in Fig. 1 for the three illustrative galaxy models and have compared the results with the analytical formula¹⁴ that applies in the case of a harmonic oscillator. Adopting the exact values of the half-period, $P_{1/2}$, and of z_{max} , we find that the curve of elapsed times is described to an accuracy of 3% by the harmonic oscillator relation: $t(z)/P_{1/2} = \frac{1}{\pi} \arcsin(z/z_{\text{max}})$.

Some explanations⁵ attribute the apparent periodicities in the extinction data to phenomena occurring at the apex of the solar vertical motion. These explanations are unlikely to be correct because they would require an extinction event that lasts a time ΔT to occur all within $7 \text{ pc} \times (\Delta T/\text{Myr})$ of z_{max} .

How much phase jitter would one expect in the times at which the Sun crosses the galactic plane? We model the (unspecified) process that causes stars to have velocity dispersions that

increase with age by calculating simulated orbits in which a model star receives a vertical kick in velocity, δv , of random sign every half period. Solar type stars have¹⁶ a z -velocity dispersion of the order of 20 km s^{-1} after 5,000 Myr (the solar age), indicating that the Sun currently has an unusually small velocity perpendicular to the plane for a star of its age. To model what happens to typical solar-type stars, we adopt $\delta v \approx 20 \text{ km s}^{-1}/(\text{solar age}/P_{1/2})^{1/2} \approx 1.6 \text{ km s}^{-1}$. For anharmonic potentials like those shown in Fig. 1, the phase jitter per half-period, $\Delta\phi$, can be estimated analytically to be of the order of

$$\Delta\phi \approx \frac{0.2\delta v P_{1/2} n^{1/2}}{z_{\text{anh}}} \quad (2)$$

where z_{anh} represents approximately the anharmonicity of the potential in the relation $\phi(z) \propto z^2/[1+(z/z_{\text{anh}})]$ and n is the number of elapsed half-periods. In deriving equation (3), we have assumed that $z_{\text{max}} \ll z_{\text{anh}}$ and $\delta v \ll v_{\text{present}}$. For an elapsed time of 250 Myr, $\Delta\phi \approx 0.8 \text{ kms}^{-1} P_{1/2}/z_{\text{anh}}$. Values for z_{anh} can be estimated from Fig. 1; the half-periods, $P_{1/2}$, are listed in Table 1. For a harmonic potential, the phase jitter per half-period is zero if the velocity kick always occurs when the Sun crosses the galactic plane; the jitter decreases like $1/n^{1/2}$ if the kicks occur with equal probability between 0 and 40 pc.

We have carried out a series of Monte-Carlo simulations of the solar vertical motion including random kicks that are given with either a uniform probability between 0 and 40 pc or always in the plane. The results are shown in Table 2. The Monte-Carlo

Table 2 Expected phase jitter for solar period from vertical kicks in velocity

Model	Location of kick (pc)	$\Delta\phi$ (median)	Quartiles
Proportional	0.0	0.035	± 0.02
	0-40	0.045	± 0.03
ISM	0.0	0.07	± 0.035
	0-40	0.07	± 0.04
All disk	0.0	0.02	± 0.01
	0-40	0.03	± 0.02

simulations are in good agreement with the analytical estimate given in equation (3). The typical phase jitter after 250 Myr is in the range 0.03–0.07 per half-period, depending on the Galaxy potential that is adopted.

The vertical oscillation period is also changed by the epicyclic motion of the Sun in the plane of the galaxy. Let the half-amplitude of the epicyclic motion be X_{max} and let h be the exponential scale length of the disk density in the plane. The average period is only slightly affected by the epicyclic motion,

$$\text{Period}(X_{\text{max}}) \approx \text{Period}(X_{\text{max}}=0) \times \left[1 + \frac{X_{\text{max}}^2}{12 h^2} \right] \quad (3)$$

The average correction due to the epicyclic motion is $<1\%$ for typical values^{11,17} of $h(3.5 \text{ kpc})$ and $X_{\text{max}}(0.5 \text{ kpc})$. However, for times short compared with the period ($\approx 160 \text{ Myr}$) of the solar epicyclic motion in the plane of the Galaxy, there is also a sinusoidal correction to the vertical oscillation period of amplitude $X_{\text{max}}/2h$. This correction could, in principle, be taken into account in making comparisons with observational data provided that the phase of the Sun in its epicyclic motion is not changed drastically during the time under consideration. On the other hand, the simplest (and most conservative) procedure is to ignore, when comparing with observations, the dependence of the period on the solar position in the galactic plane and to compute the total expected phase jitter by combining quadratically the previously computed jitter in the vertical motion (see Table 2) with an apparent phase jitter from the epicyclic motion in the plane. In this case, the expected r.m.s. phase jitter arising from the motion in the plane is $X_{\text{max}}/2^{3/2}h \approx 5\%$, comparable with the phase jitter caused by vertical kicks in velocity

The combined calculated phase jitter per vertical half-period is in the range 6–9% for all the models we have considered. This calculated phase jitter is smaller than the observed jitter in the biological and cratering data.

Finally, we note that interactions with the unseen material cannot have induced the approximately periodic features that are inferred^{1–4} from the extinction and cratering data. This conclusion follows from the work of Thaddeus and Chanan⁸, who showed that molecular clouds are not sufficiently concentrated towards the plane of the Galaxy to cause a strong preference for interactions at small heights. The unseen material cannot be more concentrated towards the plane than are molecular clouds. The maximum concentration of the unseen material towards the galactic plane that is consistent with the observations of F dwarfs and K giants is represented by the ISM model^{6–7}, in which the unseen material has an exponential scale height which is like that of the molecular clouds (corresponding to a velocity dispersion of 4 km s^{-1}). Even in this extreme model, the maximum height above the plane reached by the Sun (49 pc) is about equal to the height (45 pc) at which the density of unseen material drops to e^{-1} of its value in the plane. The Sun encounters unseen material everywhere in its orbit, with only a moderate preference for interactions in the galactic plane.

All the observed components of the Galaxy that constitute major fractions of the mass density in the solar vicinity have scale heights that are comparable with or larger than the maximum heights, z_{max} , for the Sun listed in Table 1. If something associated with passages through the galactic plane is causing periodic mass extinctions and cratering, then whatever it is cannot constitute a large fraction of the mass density, either observed or unobserved.

Increased concentration and vertical distribution of carbon dioxide in the stratosphere

W. Bischof*, R. Borchers†, P. Fabian† & B. C. Krüger†

* Department of Meteorology, University of Stockholm, S-10691 Stockholm, Sweden

† Max-Planck-Institut für Aeronomie, D-3411 Katlenburg-Lindau, FRG

Although many measurements of the abundance of CO_2 in the troposphere have been made, knowledge of its stratospheric abundances and variability is sparse. Here we report mid-latitude vertical profiles of CO_2 , up to 35 km, measured in 1979, 1982 and 1984 by analysing cryogenically collected balloon samples supplemented by air samples taken aboard aircraft. CO_2 mixing ratios are not constant with altitude but rather decrease by $\sim 7 \text{ p.p.m.v.}$ (parts per 10^6 by volume) from the tropopause to the mid-stratosphere.

The growth rate of the atmospheric CO_2 abundance caused by anthropogenic emission, which varies between 1.0 and 1.5 p.p.m.v. yr^{-1} at ground level¹, is also observed at all stratospheric heights up to 35 km. The shape of the profiles suggests that excess CO_2 above 20 km enters the stratosphere through tropical upwelling rather than mid-latitude diffusion. The time lag of this height region with respect to the tropospheric CO_2 level is ~ 5 yr.

Cryogenic sampling provides a reliable technique for collecting large stratospheric whole air samples. With the Max-Planck Institut für Aeronomie (MPAE) balloon-borne cryogenic samplers using liquefied neon as a refrigerant, samples of 30 l STP can be collected in 500 cm^3 tubes, at 8 and 15 different heights, respectively. Subsequent gas-chromatography analyses allow for simultaneously determining the concentration of 23 stable source gases, such as H_2 , CH_4 , N_2O , CO and various halocarbons. Vertical profiles of these trace constituents, up to 35 km in altitude, have already been determined in this way²⁻⁴.

For CO_2 , the infrared absorption gas analysis provides a more precise analytical technique than gas chromatography; flask samples can be analysed with a total error of $\sim \pm 0.2$ p.p.m.v. (ref. 1). This method was applied to samples collected during 1977-79 balloon flights. The profiles obtained⁵ show CO_2 volume mixing ratios decreasing from a tropopause level to a mid-stratospheric level above 20 km, by ~ 7 p.p.m.v. this decrease taking place almost entirely within the 15-20 km altitude range.

It was found, however, that these first measurements, in particular those related to 1977 and 1978 balloon samples, had suffered from contamination problems because the sample aliquots had been stored for >1 yr. Moreover, the pressure of most samples was <5 bar; for such low pressures, repetitive analyses had shown that CO_2 concentrations can drift considerably. Thus, CO_2 data analysed from most 1977/78 samples had to be discarded. Samples from two flights in June and November 1979 were analysed with a delay of four months, but still several sample aliquots had a pressure <5 bar resulting in some scatter of the data. Figure 1 shows those of the 1979 CO_2 data analysed from stratospheric samples of >5 bar. Supplementary tropospheric CO_2 data analysed from samples collected aboard commercial airliners during June and November 1979 at mid-latitudes are also shown.

On 20 September 1982, 14 stratospheric samples were recovered from a balloon flight of the MPAE 15-tube sampler, at Aire-sur-l'Adour, France (44°N). Supplementary samples were collected on 23 September aboard Concorde between Paris and New York and aboard a Boeing 747 during the return flight on 25 September. Two years later, on 1 October 1984, a tandem flight of the 8-tube and the 15-tube cryogenic samplers, at Aire-sur-l'Adour, yielded 22 samples almost equally spaced between 10 and 35 km in altitude. Supplementary aircraft samples were collected on 20 September between Stockholm and Kiruna and on 4 October between Stockholm and Frankfurt.

All analyses of the 1982 and 1984 balloon samples were made without aliquoting, that is, the original sample air was transferred directly to the gas analyser. The absolute calibration was achieved with the aid of standard gases belonging to the Stockholm calibration gas system. These gases, consisting of mixtures of CO_2 in air and frequently being compared with the calibration system at Scripps Institution of Oceanography (SIO), are related to the '1974 adjusted index' calibration scale⁶. Corrections are needed for the carrier gas effect (SIO used CO_2 in N_2 mixtures) as well as for non-linearity and drift in the SIO calibration system. Because of uncertainties that still exist in the interpretation of calibration results we present our data in the 1974-adjusted index scale. We realize that true concentrations, within the range of CO_2 values reported here, are higher by $\sim 4.0 \pm 0.3$ p.p.m.v. With sample sizes ranging between 20 and 30 l STP, the CO_2 analyses were made within two months after the flights, when sample pressures ranged between 40 and 60 bar. Repetitive analyses made two months later showed no changes of the concentrations that exceeded the error limits of ± 0.2 p.p.m.v. The 1982 and 1984 stratospheric profiles of CO_2 displayed in

Fig. 1 Vertical distribution of CO_2 between the ground- and 35-km altitude as analysed by infrared absorption of whole air samples collected aboard balloon and aircraft platforms, for 1979, 1982 and 1984. The height range of the balloon samples is shown by the symbols. The modelled profile (solid line) computed by means of a one-dimensional time-dependent model corresponds to 1980 conditions.

holds for the aircraft samples analysed immediately after the flights.

The 1982 and 1984 CO_2 profiles confirm, in general, the existence of a decreasing CO_2 content with elevation. Even more important, they confirm that this decrease is confined to the height region between 15 and 20-22 km. The stratospheric CO_2 decrease begins ~ 5 km above the tropopause which, according to aerological soundings at nearby Bordeaux meteorological station, was located at 10, 11 and 12 km during the 1979, 1982 and 1984 balloon flights, respectively. Above 20-22 km, the CO_2 mixing ratio is almost constant with altitude; the 1984 profile even shows an indication of a slight increase above 30 km.

A striking feature of the CO_2 profiles presented here is the overall similarity of the stratospheric portions above 20 km. Obviously, the general increase of the tropospheric abundance of CO_2 resulting from the burning of fossil fuel is reflected by a stratospheric increase at a corresponding rate. Mid-stratospheric mixing ratios, as averaged over the height range above 22 km, are 325.4 ± 0.5 , 329.6 ± 0.2 , and 331.6 ± 0.3 p.p.m.v., for 1979, 1982 and 1984, respectively. Annual increase rates thus amount to 1.4 p.p.m.v. yr^{-1} between 1979 and 1982 and 1.0 p.p.m.v. yr^{-1} between 1982 and 1984 or an average of 1.2 p.p.m.v. yr^{-1} over the whole time range discussed here. These rates are comparable with those observed at tropospheric levels^{1,7}.

Annual means of tropospheric CO_2 as obtained from the Stockholm project, for the years discussed here, were found to be in excess of 6.8 ± 0.9 p.p.m.v. over the stratospheric mixing ratios reported here corresponding to a time lag of 5.2 ± 0.8 yrs. The tropospheric CO_2 profiles shown in Fig. 1 are representative of late summer/autumn conditions, when the cumulative uptake of CO_2 by the vegetation reaches its maximum, thus in the annual cycle a minimum is obtained in August/September. In late winter/spring, when CO_2 is returned to the atmosphere, a maximum occurs in April/May. This seasonal variation, having a total amplitude of ~ 7 p.p.m. in the northern upper troposphere, is almost undetectable within the lower stratosphere¹.

the annual mean occurs in September. Thus, the results obtained from the lower stratosphere during autumn as shown in Fig. 1 may represent maximum rather than average conditions.

Compared with the fairly regular behaviour of mid-stratospheric profiles, the transition region below, between ~22 km and the tropopause, seems to reflect more complex features. The 1982 balloon profile, for instance, reveals exceptionally high CO₂ mixing ratios between 12 and 17 km that are comparable with or even higher than the corresponding 1984 data. As shown by the laminar structure of observed ozone profiles, transport in the lower stratosphere is largely achieved by large-scale quasi-horizontal advection. Near the tropopause, direct tropospheric/stratospheric mixing, often in connection with tropopause folding, may also be important. Either of these processes may be responsible for the high CO₂ values observed in 1982. Although some deviations between balloon and aircraft sample results exist, which are likely to result from different sampling locations, the CO₂ content below 16 km, in each of the 1982 and 1984 vertical distributions is nearly unchanged within this lower part of the stratosphere. There is a distinct change of the CO₂ mixing ratio from this layer towards the upper troposphere. This shift, as well as the rather uniform vertical distribution of CO₂ within the lower stratosphere, agrees with previous results of the Stockholm project⁸.

Our results show that stratospheric CO₂ concentrations increase with time at about the same rate as tropospheric abundances. The shape of the profiles, however, suggests that excess CO₂ from anthropogenic sources which are concentrated at northern mid-latitudes, does not simply propagate upwards there. A theoretical CO₂ profile computed for 1980 conditions by means of a time-dependent one-dimensional model, simulating vertical diffusion and following the observed growth of CO₂ at ground level³, clearly demonstrates that the observed profiles

cannot be reproduced by vertical diffusion alone. The fact that the mixing ratio gradient is confined to the height region between ~15 and 20 km and that CO₂ above that height is rather constant with altitude indicates that excess CO₂ must have entered the mid-stratosphere in a different way. We suggest that tropical upwelling is the mechanism by which the required vertical transport is probably achieved. It may carry CO₂ from the tropical troposphere to the middle and high tropical stratosphere, from where it spreads polewards. At all levels between 22 and 35 km, excess CO₂ obviously arrives with the same delay of ~5 yr with respect to the troposphere. The slight CO₂ increase above 30 km indicated by the 1984 profile suggests that the delay time for this upper region may even be shorter.

In this respect, measurements of stratospheric CO₂ profiles at tropical latitudes would be of great importance. Note that the existence of a shaped CO₂ profile as shown by our data may be relevant for satellite sounders that use the assumption of well-mixed CO₂ in the stratosphere to retrieve temperatures from infrared spectral features.

Mount Erebus is the principal source of volcanic emanations to the atmosphere in Antarctica. The rate of emission of SO₂ from Mt Erebus was determined to be 230 ± 90 tonnes day⁻¹ during an 11-day period in December 1983. This is a more accurate and much higher estimate than previous ones. Because of the very constant character of the volcano's activity from the earliest observations until September 1984, the emission rate is possibly representative of the past 20 yr. The new data are important for accurate assessment of volcanic input to the clean Antarctic atmosphere, and are a useful baseline for the changes in emission rates which will be measured now, after Erebus has begun a new energetic eruptive period.

Mt Erebus is the only active and the largest of three volcanoes which form the bulk of Ross Island, in the Ross Sea (77.55° S, 167.17° E). It is made up chiefly of anorthoclase phonolite lavas and has sustained an active lava lake, at least since 1972, and possibly for more than a century. Most of the observations of Erebus cite a persistent volcanic plume which emanates from its summit crater¹. Beginning in September 1984, Erebus has begun to exhibit much more explosive and prolific activity. The December 1983 period represents the low-level activity which

prevailed before 1984, and, therefore, represents a kind of baseline against which later observations, made during the more prolific activity, can be compared. Previously published estimates of the rate of emission of SO₂ by the Erebus plume have been 3 tonnes day⁻¹ in 1978 (ref. 2), and 35 tonnes day⁻¹ in 1980 (ref. 3). Interest in measurements of SO₂ and particle fluxes comes not only from volcanologists wishing to use such measurements to interpret the behaviour of the volcano, but also, particularly in the case of Erebus, from those trying to establish the sources of sulphate aerosol accumulations in the remote Antarctic environment⁴. Our objective was to make simultaneous and accurate airborne measurements of the gas and particle fluxes in the Mt Erebus plume. This is a report on the SO₂ measurements; we will discuss the particle data elsewhere.

To make measurements of the SO₂ fluxes, a correlation spectrometer (Barringer COSPEC-V) and an aircraft (C-130) survey method⁵ were used. The instrument is directed upwards and measures absorption of ultraviolet (290-300 nm) skylight, as the plane traverses under the plume, perpendicular to its dispersal axis. Such measurements give excellent estimates of the cross-section of the SO₂ burden, which must be multiplied by the wind speed to give the emission rate. On board the C-130 we were aided by continuous inertial navigation system readings of wind speeds (usually ~50 readings per traverse). Thus the largest source of error in such measurements was controlled very well compared with similar studies. Because of this, we believe our SO₂ flux estimates are of the highest quality. The previous estimates^{2,3} used much less direct methods and are more error-prone. Because the COSPEC measures only SO₂, the estimates obtained by this method are less than the total S flux of the volcano, because S is also produced as H₂S and as liquid and solid aerosol particles in volcanic plumes.

The general atmospheric conditions for sampling and measuring the plume on all four dates (9, 14, 17 and 19 December) were good, with clear visibility and light to moderate winds. Results of the individual SO₂ flux measurements and the measurement conditions of each of the traverses we made are

Table 1 SO₂ flux determinations, Erebus volcano, December 1983

Traverse	Distance downwind (km)	Plume width (km)	Mean SO ₂ concentration (p.p.m.v.)	SO ₂ (tonnes per day)
a, 9 December 1983. Plume thickness, 300 m; winds SE at 5–7 knots

7	3	4.2	0.24	206
1–7		$\mu \pm \sigma$		195 ± 48

listed in Table 1. The wind conditions were variable and the geometry of the plume varied considerably throughout the period 9–19 December. Concentrations of SO₂ within the plume, based on the burden measurements and width and thickness data for the plumes, were in the range 0.07–0.30 p.p.m.v. (parts per 10⁶ by volume).

On the 9 December survey a fortunate event occurred. The plume, which from a distance had appeared white and billowy was momentarily darker in colour as we approached the volcano, 20 min before the survey. This darkening of the plume was probably due to a brief (1–2 min) strombolian explosion within the crater. Similar events have been described by Kyle *et al.*¹. Considering the timing of this brief explosion, the wind speed and the times of our COSPEC traverses, it is likely that the higher fluxes of traverses 2–4 (Table 1a) are due to this

explosion. It is also probable that this event affected our particle-size distributions, which were determined at a greater distance from the volcano after the COSPEC survey. The frequency of small explosions can be estimated from seismic disturbances which are correlated with them (J. Kienle, personal communication; based on reading the seismic records of the Erebus network at Scott Base) and seems to be about 1–3 per day. Because such explosions are infrequent, and probably last only a few minutes, we suggest that they do not increase the daily flux of SO₂ by more than a few per cent, even though the rate is several times higher while the explosions occur.

Table 2 summarizes the 4 days of SO₂ flux determinations at Erebus and demonstrates the overall average of 230 ± 90 tonnes day⁻¹. Considering our knowledge of the typical behaviour of Erebus, we believe this is a good estimate of the steady-state SO₂ emission of the volcano. Because we were fortunate to make measurements during one strombolian eruption, we can show that the occasional occurrence of such events does not affect the average flux significantly. The 1983 rate of emission for Erebus is lower than most volcanoes in an active eruptive state, which frequently have been estimated to emit >1,000 tonnes day⁻¹ (refs 6, 7).

Using the SO₂ emission rate it is possible to calculate the volume of the degassing magma chamber, by the approach of Rose *et al.*⁸. Electron microprobe analyses of glass inclusions in anorthoclase phenocrysts indicate a pre-eruptive sulphur content in the phonolitic magma of 440 p.p.m. (P.R.K., unpublished data). The sulphur content of whole rock samples ejected from the lava lake averages 260 p.p.m. (P.R.K., unpublished data). Assuming a magma density of 2.7 g cm⁻³ and 20 yr of degassing, a minimum magma volume of 1.7 km³ would account for the observed SO₂ emission rate. For 80 yr of degassing the volume of magma is 6.9 km³. Although Mt Erebus has been characterized by a large vapour plume throughout this century¹, the observations before the 1960s are particularly sparse and the calculated volume of 6.9 km³ appears to be unrealistically high. We prefer the 20-yr degassing volume of 1.7 km³. This is consistent with observations which indicate no significant change in the degassing and volcanic activity of Mt Erebus since the 1960s. Also, an aerial photograph taken in November 1963 indicates the existence of a small lava lake similar to that which existed from 1972 to 1982 (ref. 1).

The sulphur content of 440 p.p.m. in the Mt Erebus anorthoclase phonolite magma is low compared with reported concentrations of 800–2,800 p.p.m. S in basaltic and andesitic glass inclusions^{9–11}. The release of the sulphur from the magma, either in the form of H₂S and/or SO₂, will be a function of several variables, including oxygen fugacity¹². Estimates of sulphur and oxygen fugacity in the phonolite of log $F_{S_2} = -2.7$ and log $f_{O_2} = -12.2$ at 1,000 °C have been made of phonolite samples using the composition of pyrrhotite and other mineral phases¹³. In such conditions the fugacity of H₂S is likely to be high¹². One would therefore predict significant emission of H₂S in the Erebus plume. Analyses of gases within the phonolite glasses show a SO₂/H₂S ratio of ~2 (E. Bigelow and P.R.K., unpublished data). Very few accurate measurements of H₂S have been made in volcanic plumes⁷ and the rate of H₂S oxidation ultimately to sulphate particles is unknown for the Antarctic environment. However, H₂S must not be ignored when assessing the contribution of Mt Erebus to the atmospheric sulphur budget

Table 2 Summary of Table 1

Date (December)	Distance (km)	Width (km)	Concentration (p.p.m.v.)	Tonnes per day (means ± σ)	Winds (knots)	No. of traverses
9	3–6	6–14	0.18–0.30	290 ± 140	5–7, SE	6

19	3	3.9–7.5	0.11–0.27	200 ± 50	8–12, WNW	7
	Overall $\mu \pm \sigma$			230 ± 90		27

for Antarctica. We are unable to quantify this contribution at present.

Our 1983 estimate of SO_2 emission from Mt Erebus is substantially higher than previous measurements. It is probable that Mt Erebus contributes significant amounts of sulphur to the Antarctic atmospheric sulphur budget. Radke³ suggested that Erebus contributed 32% of the sulphate to the budget. Delmas⁴, however, suggested that the effect of Erebus was small. Our measured SO_2 emission, excluding the possible contribution of H_2S , represents ~10% of the total Antarctic sulphur budget as estimated by Delmas⁴. Erebus is unlikely to influence the atmosphere over all of Antarctica, but its local effect may be significant. Because of the prevailing winds much of the sulphur is probably removed as aerosol over the Ross Sea, to the north of Erebus. However, as Delmas⁴ pointed out, the sulphur may be transported over large distances. Ultimately, it could circulate over the West and East Antarctic ice sheets. In addition, Erebus may contribute to the Antarctic stratosphere, especially during the winter months when the tropopause is significantly lower. A careful examination of the Antarctic sulphur budget, bearing in mind the Erebus contribution, is needed.

Because the activity of Erebus has been remarkably invariable in the period of human observations¹, we expect that the SO_2 emission rate we measured may represent a modern pre-1984 average for that volcano, which may be applied to the 1972–83

period and possibly for longer. We hesitate to conclude that the lower estimates of SO_2 flux in 1978 (ref. 2) and 1980 (ref. 3) show that the SO_2 emissions were increasing in late 1983 as a precursor of the increased activity, because the earlier estimates were made by very different methods. But the possibility that this does represent a precursive increase in SO_2 is consistent with experience at other volcanoes^{5,6}. We expect to continue SO_2 emission measurements throughout the current renewed activity to record the pattern and quantity of SO_2 release there.

‡ Department of Electrical Engineering, Kyoto Institute of Technology, Matsugasaki, Kyoto 606, Japan

§ Geophysical Institute, Kyoto University, Kitashirakawa, Kyoto 606, Japan

Microwave meteorological Doppler radars are the most efficient tool for understanding the dynamical properties of precipitating systems in the troposphere¹. However, these radars do not directly observe ambient air motion, but rather the velocity of precipitation particles within a particular region. We have recently completed very high frequency (VHF) Doppler radar at Shigaraki, Japan (34.85° N, 136.10° E) which has enabled the three-dimensional motion of both air and precipitation particles to be observed simultaneously. In particular, it enables vertical air motion as well as precipitation fall speed to be directly observed. Doppler broadening of the precipitation echo reveals features which, when above the melting layer, are characteristic of snowflakes and, when below this layer, are characteristic of raindrops. Sensitive VHF (and, most likely, ultrahigh frequency, UHF) Doppler radars equipped with fast-beam steerability open new possibilities for the investigation of the dynamical properties of precipitation particles in close combination with ambient air motion.

MST (mesosphere-stratosphere-troposphere) radars are sensitive, high-power VHF/UHF Doppler radars that can detect clear-air (refractive-index) fluctuations or turbulence in the middle atmosphere (altitude range of 10–100 km^{2,3}). Received echoes are Doppler shifted because of radial motion of the clear air turbulence (CAT). The mean Doppler shifts acquired in three different directions provide three-dimensional velocity of CAT. This velocity is shown to be equal to the ambient air motion by comparison with measurements obtained by conven-

tion^{2,4}. MST radars have rarely been used for the observation of tropospheric meteorological phenomena, with the exception of a few short-term studies of frontal zones⁵ and thunderstorms⁶.

Radar reflectivity of the inertia subrange turbulence in clear-air regions is dependent on the power law of $\lambda^{-1/3}$ (where λ is the radar wavelength). The reflectivity in the VHF band is observed to be within the range of 10^{-18} – 10^{-15} cm⁻¹ in the troposphere and lower stratosphere⁷. The power law yields a reflectivity of 5×10^{-18} – 5×10^{-15} cm⁻¹ in the microwave frequency band.

On the other hand, an estimate of the radar reflectivity for raindrops in the VHF band, for example, at 50 MHz, gives 10^{-19} – 10^{-16} cm⁻¹ for a precipitation rate of 3×10^{-1} – 3×10 mm h⁻¹, assuming the Marshall–Palmer drop-size distribution function (T. Yokoyama, personal communication). The reflectivity of the melting layer (or bright band) is ~50 times larger than that of raindrops. Thus, the reflectivity of precipitation particles at 50 MHz is within the range of 10^{-19} – 5×10^{-15} cm⁻¹, which is essentially the same range as that of CAT. This value is nine orders in magnitude smaller than that of microwave radars.

Because the reflectivities of both CAT and precipitation particles at 50 MHz are in the same range, sensitive 50-MHz MST radars are expected to detect simultaneously both types of echoes from precipitating air. This contrasts with the situation found in microwave radars, where precipitation echo is much more dominant than CAT echo. This is because the microwave reflectivity of precipitation particles is 4–12 order of magnitude larger than that of CAT.

The middle and upper atmosphere radar (MU radar) located at Shigaraki, Japan is a 46.5-MHz radar using an active-phased array system⁸. It is composed of 475 Yagi antennas and an equivalent number of solid-state power amplifiers (transmitter-receiver (TR) modules)⁹. Each Yagi antenna is driven by a TR-module with peak output power of 2.4 kW. The nominal peak and average radiation powers of the whole system are 1,000 and 50 kW, respectively. This system makes it possible to steer the antenna beam up to 30° from the zenith in each interpulse period.

Recently, we have observed precipitating air in the troposphere, using the fast beam steerability of the MU radar. We present the preliminary results of a short-term study which was successfully conducted on 22 August 1984. The full capabilities of the MU radar system were only partially employed. A nominal beam width of 4.0° and peak transmitted power of 760 kW were

Fig. 1 Doppler velocity spectra plotted against altitude obtained in the vertical direction by the MU radar, Shigaraki, Japan. The observational periods are: *a*, 0845–0851 JST (Japan Standard Time) and *b*, 0750–0756 JST on 22 August 1984. The ordinate is relative power in decibels with an arbitrary reference level. The abscissa is represented in terms of radial (vertical) Doppler velocity (Note that the sign is given in the reverse direction.) The positive and negative speeds correspond to departure from and approach to the MU radar, respectively. This usage is the opposite of the meteorological convention. *c*, *d*, Same as *a*, except *c* is northward and *d* is the eastward beam direction. The spectra are plotted against radial Doppler velocity.

resolution of 150 m. Echoes were sampled above 2.4 km from ground level (375 m above sea level) to obtain the delay required to protect the TR modules. The beam was steered during each interpulse period of 400 μ s sequentially to three different directions: zenith and 15° away from the zenith to the north and east. At an altitude of 5 km, the distance separating the off-vertical beams from the vertical beam was 1.3 km.

The bipolar video signal from each beam was sampled at 64 points spaced in the region from 2.4 to ~ 12 km aloft at 150-m intervals. 128 point complex fast Fourier transforms were calculated in real time to obtain Doppler velocity spectra for each 7.7-s period. The resulting power spectra were averaged for ~ 1 min before being written on magnetic tape.

Figure 1*a, b* shows typical altitude variations of the Doppler velocity spectra obtained in the vertical direction during periods (*a*) with and (*b*) without perceivable precipitation on the surface. Each spectrum is the average of a 6-min period. The surface rainfall rates during these periods were 1 and 0 mm h^{-1} , respectively, as observed by the Japan Meteorological Agency at their

facility in Kinose, 6.9 km north of the MU radar. The rainfall is classified as being of the weak stratiform type.

Of the spectral components illustrated in Fig. 1, the minor one with comparably large negative (downward) Doppler shift exists only when precipitation is observed (Fig. 1*a*), whereas the major one with near zero Doppler shift appears persistently irrespective of precipitation.

Figure 1*c, d* clearly illustrates the correspondence of these spectral components to those obtained in the northward and eastward beam directions. For the major spectral component, horizontal velocity is calculated by assuming the presence of a uniform velocity field within the region illuminated by the three beams (Fig. 2). The result is compared with the horizontal wind velocity measured by rawinsondes launched from Shionomisaki, ~ 150 km south of Shigaraki, and from Wajima, 250 km north. The radar-deduced horizontal velocity is consistent with the meteorological wind field, the difference between the three locations is in accord with that usually observed below 12 km (ref. 9). The vertical velocity shown in Fig. 2 is directly measured by the vertical beam.

Fig. 2 Altitude variation of vertical and horizontal components of air motion estimated from the major spectral component present in Fig. 1*a, c, d* (solid line). Positive vertical speed indicates updraft of air. Horizontal velocity is given in terms of wind speed and direction following the meteorological convention. The beams in the northward and eastward directions that are tilted 15° off from the zenith sample echoes at a range 100–300 m lower in altitude than that of the vertical beam. This altitude difference is taken into consideration when determining three-dimensional velocities by interpolating the vertical speed at the corresponding altitudes with a spline function. Comparisons are made with horizontal winds measured by rawinsondes launched from Shionomisaki, 150 km to the south of

Fig. 3 Mean vertical (fall) speed and horizontal velocity of precipitation particles plotted against altitude estimated from the minor spectral component in Fig. 1a, c, d. Positive vertical speed indicates updraft. The ambient atmospheric wind velocity shown in Fig. 2 is also given by dashed lines for comparison. Precipitation particle motion is not given above 8.69 km, because the spectral component due to precipitation particles merges with that of ambient air origin above this altitude.

Below 5 km, the vertical speed of the minor spectral component is $\sim 7 \text{ m s}^{-1}$, whereas it is $< 2 \text{ m s}^{-1}$ above 6 km (Fig. 3). This change in the altitude range of 5–6 km is quite certain, because the minor spectral component clearly separates from the major one $\approx 8.5 \text{ km}$. It merges with the major component $\approx 9 \text{ km}$.

During periods when rainfall was perceived at the surface level, the melting layer was detected at 5.4 km by a dual frequency (C/Ku band) microwave radar located next to the MU radar¹⁰. Both spectral components of the 46.5-MHz radar echo are also enhanced at this altitude; the enhancement of CAT echo presumably results from a signature in the vertical temperature gradient in the melting layer.

The spectral width of the minor spectral component varies by more than three times near 5–6 km, ranging from 0.8 m s^{-1} above and 2.7 m s^{-1} below the melting layer. It is roughly constant elsewhere.

The above features concerned with vertical speed and spectral width are consistent with those of precipitation particles observed with meteorological Doppler radars^{1,11}. This would indicate that the minor spectral component of the MU radar echo originates from precipitation particles, that is, snowflakes above and raindrops below the melting layer. Note that, by using Doppler velocity spectra obtained by the vertical beam of the MU radar, drop-size distribution functions can be directly determined, obviating the need to make assumptions concerning vertical air motion. By and large, this type of direct measurement is not feasible using conventional meteorological radars.

Mean horizontal speed of precipitation particles is inferred in the same way as that of air (Fig. 3). The precipitation particles of the weak stratiform rain in the present example generally follow the ambient air motion. However, a detailed investigation of the differential motion would certainly be of interest.

In the present observation of a weak stratiform rain, vertical beam and two off-vertical beams with 15° off-zenith angles were used. This assumes that the wind field is uniform over the area containing the three beams, a region $\sim 2 \text{ km}$ at an altitude of 5 km. The assumption of wind field uniformity is necessary in monostatic wind vector measurements. However, it may be a source of error in convective storm environments. Depending on spatial scales of meteorological phenomena observed, a combination of three (or more) beams can be arbitrarily selected from the 1,657 directions within 30° off-zenith angle to which the MU radar can steer its beam. To provide significant three-dimensional motion, minimum beam separation can be reduced to beam width, or 350 m at an altitude of 5 km. This spatial resolution is sufficient to enable the observation of precipitating systems of a moderate size and larger.

Although the MU radar is capable of observing a substantial part of the deep and strong updrafts associated with frontal passages or convective storms which generally extend above an altitude of 10 km, it cannot provide the information concerning activities in the planetary boundary layer. Therefore, simul-

and/or other conventional instruments (such as the rawinsonde) will have an important supporting role in future investigations of the tropospheric meteorological phenomena which employ the MU radar.

We thank Professor T. Matsuno of the University of Tokyo and to Dr. H. Tanaka of Nagoya University for constructive suggestions.

Indirect electrochemical degradation and dissolution of coal by means of persulphate

G. Kreysa & W. Kochanek

Dechema-Institute, Theodor-Heuss-Allee 25,
D-6000 Frankfurt/M. 97, FRG

The idea of electrochemical coal conversion has recently been revived^{1–7}. The mechanism of anodic coal oxidation has been shown to be indirect and that the electron transfer is mediated by $\text{Fe}^{3+}/\text{Fe}^{2+}$ leached out of the coal. Although the application of various mediator systems has been discussed in detail, all these systems suffer from either comparatively low reaction rates or high CO_2 current efficiencies. Caro's acid (H_2SO_5), obtained as a hydrolysis product during anodic persulphate formation is a powerful redox mediator system for the degradation of the macromolecular coal structure in mild conditions, providing a nearly complete dissolution of coal in sulphuric acid. We propose here that the high current efficiencies accompanied by low CO_2 evolution might open a route of potential interest for the electrochemical production of aromatic carboxylic acids from coal.

This redox mediator system has not previously been described, although there seems to be a similarity between Caro's acid and TFA (trifluoroperacetic acid) the application of which is described elsewhere^{8,9}. However, there are two significant differences. First, TFA destroys aromatic structures to such an extent that Deno proposed TFA-oxidation as a suitable tool for estimating the aliphatic carbon content in coal. The second

Fig. 1 Mechanism of oxidative coal cleavage by Baeyer-Villiger/Oxidation and consecutive saponification. R and R' represent the rest of the coal structure.

trifluoroacetic acid in conditions which are suitable for industrial application.

The special chemical and electrochemical features of the oxidant persulphuric acid have been described as follows: (1) Despite the high redox potential ($E^\circ = 2.05$ V), persulphate itself reacts, in general, very slowly. (2) In strongly acid solution, $H_2S_2O_8$ is hydrolysed depending on the reaction conditions in accordance with the following scheme

(3) The efficiency of anodic $S_2O_8^{2-}$ formation depends on the concentration of H_2SO_5 since the latter can depolarize the anode with formation of O_2 and H_2SO_4 (ref. 13). (4) Caro's acid (H_2SO_5) is a very strong and highly reactive redox mediator and oxidizes carbonyl groups giving rise to esters and lactones. The mechanism of this 'Baeyer-Villiger-oxidation' reaction, is given in Fig. 1. (All examples of the Baeyer-Villiger-oxidation up to 1953 are reviewed in ref. 14. Many of the compounds mentioned may serve as model substances for coal.)

Coal has a macromolecular structure containing condensed aromatic systems linked together by aliphatic bridges, the most abundant of which are methylene bridges. These units may be easily oxidized to carbonyl groups in the presence of $S_2O_8^{2-}$, SO_3^{2-} or H_2O_2 . A consecutive Baeyer-Villiger-reaction would result in the formation of esters which are supposed to undergo saponification in the strong acid media. By this sequence of reactions, C-C bonds connecting aromatic units in coal should be cleaved giving rise to the formation of low-molecular aromatic carboxylic acids. Because Caro's acid is consumed thereby, the current efficiency for anodic persulphate formation should be improved in the presence of coal according to point (3) above. These assumptions are confirmed by the experimental results which have been obtained in the system $S_2O_8^{2-}/H_2SO_4$ both with and without electrochemical regeneration of the oxidant.

If a given amount of coal (Westerholt-Kohle, West Germany; 2.4 g; <500 μm) is suspended in 300 cm^3 91 wt% sulphuric acid and stirred at 37 °C for 1 h no significant degradation of the coal takes place. If this experiment is repeated in the presence of $Na_2S_2O_8$, the electrolyte quickly turns brown and the coal quantity recoverable by filtration is decreased. This is shown in Fig. 2 for various amounts of $Na_2S_2O_8$ consecutively added to the suspension (curve a). The gas evolved during the reaction (curve c) is mainly O_2 formed by a parallel decomposition of Caro's acid. This gas contains only small amounts of CO_2 . The

Fig. 2 Coal degradation as function of $Na_2S_2O_8$ consumption. a, Coal recoverable by filtration; b, precipitable acids; c, gas evolution.

losses of $Na_2S_2O_8$ due to gas formation were found to be <25% even at high degrees of coal oxidation.

The detached electrolytes from the experiments given in Fig. 2 were diluted with water in the ratio of 1:6. A deep-brown precipitate of carboxylic acids was collected, the amount of which is shown by curve b. The decrease of the precipitate yield at $Na_2S_2O_8$ consumption >24 g has to be attributed to consecutive oxidation of these intermediates. Thereby, a further breakdown can be achieved which finally results in the formation of low-molecular acids which are soluble and cannot be precipitated by dilution. Oxidative coal degradation follows the common sequence¹⁵:

But it is also known¹⁶⁻¹⁸ that the first step in this sequence is rate determining and cannot be obtained by mild oxidants such as H_2O_2 . Therefore, we were mainly interested in the formation of these intermediates, sometimes termed 'regenerated humic acids', because their consecutive conversion do not need the high redox potential of the persulphate system. In contrast with other oxidants, such as MnO_4^- , O_3 or HNO_3 a complete dissolution of coal can be achieved within a few hours using Caro's acid. Table 1 shows that there is a drastic change in the O/C-ratio between the intermediate acids and the native coal whereas, in spite of the reaction medium used, the sulphur content remains unchanged.

Infrared and nuclear magnetic resonance (NMR) spectral analysis data show that the aromatic basic structure of the coal is preserved within these acids. About 4-6 carboxylic groups per molecular unit were found whereas only a few aliphatic protons can be detected.

The experiments reported here were conducted at 37 °C with a H_2SO_4 concentration of 91 wt%. These conditions were found to be optimum with respect to reaction rate and $Na_2S_2O_8$ losses through gas evolution. At elevated temperatures in sulphuric acid of low concentration, the reaction mixture is decomposed to yield O_2 and O_3 with no significant dissolution of coal, whereas at higher H_2SO_4 concentrations and higher temperatures (~100 °C) parallel SO_2 evolution was observed.

Kinetic investigations have shown that the reaction rate is strongly influenced by H_2SO_4 concentration and that in 3 M sulphuric acid no conversion of coal can be achieved. The same trend was found in $HClO_4$. This fact is in accordance with the proposed reaction mechanism in which the real oxidizing agent is not the persulphate itself but Caro's acid the equilibrium concentration of which depends on the proton concentration¹¹.

Investigations^{13,19} have shown that a high current efficiency for electrochemical formation of persulphate can only be achieved in the following conditions: high current density of ~0.5-1 A cm^{-2} ; low temperature in the range of ~10-15 °C; high SO_4^{2-} concentration; in conditions where the accumulation of H_2SO_5 in the electrolyte is avoided.

This situation is shown in Fig. 3a, where a current efficiency

Fig. 3 Differential current efficiency of anodic persulphate formation with and without coal: a, no coal; b, with 7.36 g coal; c, with 14.72 g coal. $\text{H}_2\text{SO}_4 = 65\%$; temperature 10°C ; current 0.75 A ; area of electrode 1 cm^2 ; volume of reactor, 460 cm^3 .

decreases with increasing accumulation of Caro's acid in the electrolyte. Three main effects are observed when the same experiment is repeated in the presence of coal.

First, neither the ash content nor the coal itself or its oxidation products reduce the current efficiency of the electrolysis. Second, no significant differences with respect to coal dissolution is found if electrochemically-regenerated persulphate were used. This can be shown by a further experiment. A total charge of $44,500\text{ C}$ has been applied corresponding to the formation of $0.134\text{ mol S}_2\text{O}_8^{2-}$ with an integral current efficiency of 58.1% determined by measuring the amount of oxygen produced. This electrochemically-formed $\text{S}_2\text{O}_8^{2-}$ dissolved 0.881 g of the 8.16 g of coal used in this experiment, corresponding to a relative coal dissolution of 10.8% . This means a relative persulphate consumption of $0.152\text{ mol S}_2\text{O}_8^{2-}\text{ g}^{-1}$ dissolved coal. For the chemical coal dissolution experiment (Fig. 2) at the same relative degree of coal conversion a persulphate consumption of $0.150\text{ mol S}_2\text{O}_8^{2-}\text{ g}^{-1}$ dissolved coal can be inferred which is in close agreement with the electrochemical experiment. Third, the decrease of current efficiency with time is not as steep as in pure H_2SO_4 , and depends on coal concentration.

The third observations were predicted on the basis of the reaction scheme outlined above, whereas the other observations could not be taken for granted.

The fact that there is still a decrease in current efficiency with increasing charge consumption, even in the presence of coal, has to be attributed to the low reaction rate caused by the low temperature needed in the electrochemical cell. Therefore, an outer cell process seems to be more appropriate where a coal slurry of high concentration is passing the electrochemical cell at low temperature levels and is oxidized in a chemical reactor at about $30\text{--}35^\circ\text{C}$. From the data given in Fig. 3 and from present investigations, a high constant current efficiency can be realized²⁰.

Noble gases from oceanic island basalts do not require an undepleted mantle source

David E. Fisher

University of Miami, Rosentiel School of Marine and Atmospheric Science, Miami, Florida 33149-1098, USA

Several lines of evidence based on relative rare earth abundances and on strontium, lead and neodymium isotopic geochemistry have led to the suggestion that the Earth's mantle may be divided roughly into a region depleted in volatile components, feeding the mid-ocean ridge basalts (MORB's), and a less depleted ('undepleted') region which feeds hotspots and thus oceanic island basalts (OIB's) such as Iceland and Hawaii. Models of mantle degassing and atmospheric evolution have been based on differences in argon and xenon isotope ratios measured in samples which supposedly trap rare gases from these two reservoirs¹⁻⁷. However, the ultra-mafic Ar and Xe that were first suggested as samples of the undepleted mantle were subject to air contamination and diffusion loss, so that the experimental results are not definitive⁸. New heavy rare gas data on volcanic glasses from Hawaii and Iceland are more directly comparable with the MORB glass data, and supposedly show the isotope pattern expected from the undepleted mantle^{2,5}. As I report here, however, absolute abundances and elemental ratios corrected for mass fractionation effects indicate that partial loss of the depleted mantle component plus addition of an atmospheric Ar and Xe component provide a better rationale for the isotopic differences in these heavy gases than does the postulated undepleted mantle component.

Table 1a summarizes the evidence cited. The trapped component seen in all oceanic glasses (Table 1a) has a $^3\text{He}/^4\text{He}$ ratio higher than atmospheric; as the source is shielded from any extraterrestrial influx, this must indicate a primordial component; the argument continues that the higher ratio seen in the supposedly undepleted glasses then indicates a more primitive source, that is, a more undepleted source.

This difference in ratios between the two mantle components could not have been quantitatively predicted *a priori*, because the undepleted mantle must contain not only higher abundances of the primordial gas (with respect to the depleted mantle), but also more uranium and therefore more radiogenic ^4He . The balance between the primordial ^3He and ^4He and the radiogenic ^4He is impossible to calculate because we do not know the fractionation factor between He and U in mantle processes, the fraction of the original mantle depleted in both the depleted and undepleted (actually merely less depleted) regions, or the time interval since the depletion process or processes occurred.

The $^{40}\text{Ar}/^{36}\text{Ar}$ ratio in the atmosphere is 295.5. The high ratio seen in the depleted samples results from potassium decay in the mantle and therefore is a firm fingerprint for a non-atmospheric origin. The nearly-atmospheric ratio in the undepleted samples has been interpreted as resulting from K-decay in a mantle region where the $\text{K}/^{36}\text{Ar}$ ratio is similar to that which has fed the atmosphere, and is much lower than that of the depleted mantle region because of a much higher primordial ^{36}Ar content⁷. However, the nearly-atmospheric $^{40}\text{Ar}/^{36}\text{Ar}$ ratio seen in the undepleted samples (Table 1a) could also be due to incomplete trapping of mantle Ar with unknown (perhaps depleted-type) isotopic ratios plus atmospheric contamination.

The higher than atmospheric $^{129}\text{Xe}/^{130}\text{Xe}$ ratios reported for (depleted) MORB glasses were interpreted as caused by the radioactive decay of ^{129}I after a significant fraction of the primordial Xe had been removed, implying that the depletion of the mantle took place early in the history of the Earth^{4,5}. This interpretation has been contested on various grounds (ref. 9 and R. Hart, personal communication), however, and conflicts with previous data from Hawaiian ultramafic nodules, where a slight anomaly was found in both the supposedly undepleted and

Table 1 Summary of rare gas ratios (a) and abundances (b) in oceanic glasses

Atmosphere			1.15	295.5	648						

depleted samples^{6,10,11}. The atmospheric Xe ratios in the OIBs may be evidence of a greater primordial/radiogenic ratio or, alternatively, of a greater atmospheric component.

I propose two arguments to the effect that the observed differences between the two groups of samples result from diffusion loss of mantle gases from and incorporation of atmospheric-type rare gases into the undepleted mantle samples, masking any possible Ar and Xe mantle signatures. First, consider the absolute abundance data for these samples shown in Table 1b. The undepleted mantle should have higher concentrations of all the rare gases than has the depleted system, yet the depleted samples show higher abundances of ³He, ⁴He, ⁴⁰Ar, and fissionogenic ¹³⁶Xe (¹³⁶Xe_f). (A very few MORBs have lower trapped rare gas abundances; the vast majority lie within the limits shown.) If the OIBs really represent undepleted mantle, it follows that they trapped the mantle gases less efficiently than did most MORBs. They were emplaced under shallower water depths, which may certainly explain the observed abundances; nevertheless, without arguing for any particular mechanism, the fact of lesser trapping efficiencies for the OIBs is inescapable if they are to be thought of as arising from the undepleted mantle. And yet these undepleted samples have generally higher abundances of ³⁶Ar, which is precisely the isotope most affected by atmospheric contamination. Thus, the absolute abundances indicate both incomplete trapping and atmospheric contamination, rather than support for the depleted/undepleted mantle concept.

This interpretation is supported by the second argument, which relies on elemental abundance ratios. Such values are notoriously unreliable as model foundations because they are easily influenced by mass fractionating mechanisms; however, some of the data sets have a built-in mass fractionation monitor, the ⁴He/¹³⁶Xe_f ratio¹². ⁴He is the radiogenic daughter of U and Th and their daughters, while ¹³⁶Xe is the fissionogenic daughter of ²³⁸U. (Allègre *et al.*⁵ erroneously claim ²⁴⁴Pu as the fissionogenic nuclide parent; see ref. 9 for a clarification of this point.) The ratio is constant over long periods of geological time, and other evidence indicates that accumulation of the radiogenic rare gases in these samples has indeed proceeded for time periods of the order of hundreds of millions of years⁹. Possible variations in the Th/U ratio introduce only a small variation. Thus, if the ratio found in a sample which has trapped mantle gases is higher than the production ratio of 4.2×10^8 (±10%) (see ref. 12), it reveals the operation of positive mass fractionation (enrichment of the lighter gas), presumably during the mantle/crust emplacement process, while values lower than the production ratio indicate loss of the lighter gas (presumably through diffusion during or after eruption). If this radiogenic/fissionogenic ratio in a particular sample has been thus altered by mass fractionation, the comparable primordial ratio ³He/¹³⁰Xe must necessarily have been identically altered. Therefore, if a suite of samples has trapped rare gases from mantle source regions of identical He/Xe ratios, the measured ⁴He/¹³⁶Xe_f ratios will be proportional to the measured ³He/¹³⁰Xe ratios, regardless of whether any mass fractionation process has been operating on them:

$${}^3\text{He}/{}^{130}\text{Xe} = k_1 ({}^4\text{He}/{}^{136}\text{Xe}_f) \quad (1)$$

where k_1 is a constant. This is borne out by the MORB data of Table 2 (which includes all data sets for which the Xe isotope data are measured sufficiently precisely to allow an estimate of the fissionogenic component of ¹³⁶Xe): with a variation in

⁴He/¹³⁶Xe_f of a factor of 25 and more than an order of magnitude in absolute He and Xe abundances, k_1 remains constant to within ±50%. The surprise is that k_1 for the undepleted samples of Table 1b is identical. (The value for KK-29-10 is only an upper limit because only an upper limit to the ¹³⁶Xe_f can be calculated from the data.) This requires explanation. The ratio of trapped, mass-fractionated gases found in MORBs or elsewhere is related to that of the mantle source region by

$$({}^i\text{He}/{}^j\text{Xe})_{T,\alpha} = k({}^i\text{He}/{}^j\text{Xe})_\alpha \quad (2)$$

where i and j are mass numbers, k is a constant related to the i - j mass difference, α identifies the source region and T,α indicates the trapped component arising from source region α . Then, for a sample trapping rare gases from an undepleted source region ($\alpha = 0$),

$$({}^3\text{He}/{}^{130}\text{Xe})_{T,0} = k({}^3\text{He}/{}^{130}\text{Xe})_0 \quad (3)$$

$$({}^4\text{He}/{}^{136}\text{Xe}_f)_{T,0} = k({}^4\text{He}/{}^{136}\text{Xe}_f)_0 \quad (4)$$

leading to equation (1) where $k_1 = ({}^3\text{He}/{}^{130}\text{Xe})_0 / ({}^4\text{He}/{}^{136}\text{Xe}_f)_0$. The depleted mantle source region of the MORB will have lost more He than Xe in the depletion process (as is evidenced by MORBs showing ⁴He/¹³⁶Xe_f ratios higher than the production ratio), but the $({}^4\text{He}/{}^{136}\text{Xe}_f)_0$ ratio will soon be re-established through continued radiogenic production; the $({}^3\text{He}/{}^{130}\text{Xe})_0$ ratio, on the other hand, is permanently reduced. Therefore

$$({}^3\text{He}/{}^{130}\text{Xe})_{T,D} = k_1' ({}^4\text{He}/{}^{136}\text{Xe}_f)_{T,D} \quad (5)$$

where D indicates the depleted mantle, and

$$\begin{aligned} k_1' &= ({}^3\text{He}/{}^{130}\text{Xe})_D / ({}^4\text{He}/{}^{136}\text{Xe}_f)_D \\ &= ({}^3\text{He}/{}^{130}\text{Xe})_D / ({}^4\text{He}/{}^{136}\text{Xe}_f)_0 \\ &= k_1 ({}^3\text{He}/{}^{130}\text{Xe})_D / ({}^3\text{He}/{}^{130}\text{Xe})_0 \neq k_1 \end{aligned} \quad (6)$$

The ratio $({}^3\text{He}/{}^{130}\text{Xe})_D / ({}^3\text{He}/{}^{130}\text{Xe})_0$ is not unity because of mass fractionation during the depletion process, and therefore $k_1' \neq k_1$. The value of the ratio can be estimated from the data shown here and in previous work. The reasoning is as follows.

Table 2 Rare gas elemental fractionation ratios

Either the argon in the OIBs contains an atmospheric component or it does not. If it does, its isotopic composition is not representative of the undepleted mantle; it is only a lower limit to that composition, the exact value being dependent on the relative amounts of trapped mantle and atmospheric argon. If the argon in the OIBs contains no atmospheric component, we may use the measured argon concentrations in OIB and MORB samples as an estimate of the relative degassing that has taken place between the depleted and undepleted mantle, and therefore of the mass fractionation that must have occurred.

^{36}Ar in MORBs has been shown to be a mix of trapped mantle argon and atmospheric contamination^{9,13,14}; limits of trapped mantle ^{36}Ar are $\leq 1.5 \times 10^{-10} \text{ cm}^3 \text{ g}^{-1}$, STP. The highest ^{36}Ar content of OIBs is 12×10^{-10} (Table 1b). We assume for the moment that this represents argon trapped from the undepleted mantle rather than atmospheric contamination; it is a lower limit (compared with the MORB data), as it is clear from the He data that the OIBs have retained less of their mantle-inherited rare gases than have the MORBs. Then the basalts from the depleted mantle have trapped less than 10% of the argon trapped in basalts from the undepleted mantle, although their trapping efficiency is greater; the depletion factor must therefore be greater than an order of magnitude. Given that the mass fractionation occurring during the depletion is proportional to the square roots of the masses, it follows that the ratio $(^{3}\text{He}/^{130}\text{Xe})_{\text{D}}/(^{3}\text{He}/^{130}\text{Xe})_0$ remaining in the two mantles today must be less than 0.017 and therefore $k_1 \leq 0.017 k_i$. However, the data of Table 1b cannot be reconciled with this result; the single value of k_i for both MORBs and OIBs flatly contradicts the expectation based on the concept of depleted and undepleted mantle regions outlined above. I suggest that the large enrichment of k_1 actually observed in the supposedly undepleted samples is a result of the $(^{3}\text{He}/^{130}\text{Xe})_0$ ratio in these samples being lessened by both loss of mantle ^3He and addition of atmospheric ^{130}Xe . This addition of atmospheric Xe is also responsible for the roughly atmospheric $^{129}\text{Xe}/^{130}\text{Xe}$ ratios in these samples.

The analysis can be extended to the Ar/Xe ratio:

$$^{36}\text{Ar}/^{130}\text{Xe} = k_2(^4\text{He}/^{136}\text{Xe}_t) \quad (7)$$

This time a distinct difference is seen between the two groups of samples (Table 2); the constant k_2 is much greater for the undepleted group, indicating either too much ^{36}Ar or too little ^{130}Xe . Since k_1 is identical for both groups, the simplest conclusion is that the samples interpreted as undepleted have an excess of ^{36}Ar . This excess of ^{36}Ar is the outstanding characteristic of samples which have undergone atmospheric contamination, as our atmosphere has a low $^3\text{He}/^{36}\text{Ar}$ ratio and a high $^{36}\text{Ar}/^{130}\text{Xe}$ ratio relative to the planetary primordial component.

The mode of incorporation of the atmospheric gases is unclear. The temperature release patterns of ref. 5 suggest that it is actually dissolved in the glass. If this is so, it may represent an atmospheric component injected into the magma source region rather than what is generally called 'atmospheric contamination'—surface adsorption following emplacement of the magma on the Earth's surface.

To conclude, the rare gas isotope ratio patterns of Table 1a, which have been offered as evidence of gases trapped from the undepleted mantle, are not convincing; two of the three (the $^{40}\text{Ar}/^{36}\text{Ar}$ and $^{129}\text{Xe}/^{130}\text{Xe}$ ratios) could equally well be explained by an atmospheric rather than an undepleted component. The data of Tables 1b and 2 cannot be explained by an undepleted mantle component but are perfectly explicable in terms of incomplete trapping and atmospheric admixture. The one data set that seems to indicate the existence of the undepleted mantle, the $^3\text{He}/^4\text{He}$ ratio, is also the one that would be least affected by the presence of an atmospheric component. It follows that modelling of mantle evolutionary histories and atmospheric formation which are based on Ar and Xe isotope differences between the depleted and undepleted mantle are not supported by such data as are now available.

The radiogenic Th isotopes (^{234}Th , ^{230}Th and ^{228}Th) are produced *in situ* in the ocean from their dissolved progenitors (^{238}U , ^{234}U and ^{228}Ra , respectively). These parent-daughter pairs have extensively been used to study the rate and mechanism of chemical scavenging, a process that is believed to be important in controlling the distributions and concentrations of many trace metals, such as Be, Al, Cr, Mn, Fe, Co, Cu, Pb and the rare earths^{1–12}. However, it is difficult to make useful direct comparisons between the distributions of the radiogenic Th tracers and those of trace metals, because their input pathways to the ocean are very different. To provide a link, one needs to determine the water-column distribution of the dominant isotope ^{232}Th , which is non-radiogenic and is thus delivered to the ocean by the same fluvial and aeolian pathways as most trace metals. However, with the exception of the near-bottom measurements recently reported by Nozaki and Horibe¹³, little is known of the concentration level of ^{232}Th or its distribution pattern in the ocean. We report here the first profile showing the complete distribution of ^{232}Th in an oceanic water column from the Venezuelan Basin. The data were obtained by a sensitive neutron activation analysis method newly developed for this project. The profile shows relatively high concentrations in the upper 200 m with a maximum of $87 \text{ d.p.m.}/10^6 \text{ kg}$ near the base of the mixed layer. Average concentrations in deeper water ($2.7 \text{ d.p.m.}/10^6 \text{ kg}$) are uniform and atypically low compared with open-ocean deep waters, perhaps because of unusually rapid scavenging in the restricted basin. The source of the ^{232}Th in the surface waters is not known, but rivers appear to be more likely candidates than the atmosphere.

The samples were collected at $14^\circ 31' \text{ N}$, $66^\circ 8' \text{ W}$ during R/V *Knorr* Cruise 99–2 in November 1982. The seawater was filtered ($1 \mu\text{m}$ pore-size Nuclepore filters) and drained into 10-l acid-cleaned jerryjugs directly from the PVC Niskin samplers. Following collection, 12.5 cm^3 double quartz-distilled 8M HCl was added to each sample to bring the pH to ~ 2 . A full description of the clean sampling and filtration procedures used at sea is given elsewhere¹⁴.

Analysis in the shore-based laboratory began with additions of purified Fe^{3+} carrier and ^{230}Th spike to the acidified water. After several days for equilibration, ammonium hydroxide (ULTREX) was added to effect $\text{Fe}(\text{OH})_3$ precipitation. The

precipitates were collected by centrifugation and then dissolved in HCl. Separation and purification of Th-isotopes were done by anion and cation exchange and solvent extraction according to the method of C.-A.H.¹⁵ with minor modifications. The final source (in thenoyltrifluoroacetone/benzene) was mounted onto a high-purity (Puratronic) Al foil (2.5 cm diameter, 0.025 mm thickness). The Th recovery, based on ²³⁰Th, was determined with a proportional counter.

The sample foils, together with standard and blank foils, were packed in a polyethylene vial and irradiated with a thermal neutron flux of 5×10^{13} neutron $\text{cm}^{-2} \text{s}^{-1}$ for 6 h at the MIT Nuclear Reactor Laboratory. After removal from the reactor, the samples were allowed to cool for four days before the post-irradiation extraction of ²³³Pa (induced from ²³²Th).

The irradiated Al foils were dissolved in concentrated HCl and spiked with ²³¹Pa. The procedure for Pa (²³¹Pa and ²³³Pa) extraction was the same as that given in ref. 15, and the final source was made on a stainless steel disk. The Pa yield was determined by α -counting ²³¹Pa in a proportional counter. The ²³³Pa was determined by β -counting ²³³Pa in the same proportional counter. The purity of the Pa source was confirmed by the distinct 312-keV γ -radiation observed in a γ -spectrometer and by the decrease of β -activity being consistent with the half-life (27 days) of ²³³Pa. A complete description of the analytical procedures is given elsewhere¹⁶.

In dealing with the extremely low ²³²Th activities in the samples, we were aware of the potential for sample contamination and the importance of blank correction. Four sample blanks (reagents + Al foil) and three foil blanks (Al foil only) were prepared along with the samples and standards. Figure 1 shows, for these blanks, the relationship between the activity of ²³³Pa detected and the recovery of Pa in the post-irradiation chemical procedure. Two straight regression lines, one drawn for the sample blanks (SB1-4) and one for the foil blanks (FB1-3), are shown in Fig. 1. The offset of these two lines (that is, sample blank above foil blank) is a measure of the reagent blank, which turns out to be small compared with the foil blank. The good fit of the lines to the points indicates that ²³²Th on the Puratronic Al foil, although it exists at an easily detectable level, is evenly distributed in the material. The regression line for the sample blanks was used in making blank corrections for the samples and standards.

Fig. 1 The ²³³Pa/Pa yield relationship for the sample blanks (□) and Al-foil blanks (○). The slight offset of the two regression lines indicates that the foil blank dominates over the reagent blank.

Four ²³²Th standards, ranging from 0.01 d.p.m. to 2 d.p.m. (disintegrations per minute), were prepared from high purity ThO₂ (Lindsay Code 116, >99.9% purity) and run through the same procedures with the samples. A linear response resulted, as expected (Fig. 2); the regression coefficient is 1.24×10^6 (counts per minute, c.p.m. ²³³Pa/d.p.m. ²³²Th). The activities of ²³²Th in the samples were then calculated using the equation:

$$^{232}\text{Th (d.p.m. kg}^{-1}) = \frac{(\text{c.p.m. } ^{233}\text{Pa})_{\text{measured}} - (\text{c.p.m. } ^{233}\text{Pa})_{\text{blank}}}{(\% \text{ Th yield}/100)(\% \text{ Pa yield}/100) 1.24 \times 10^6 (\text{c.p.m.}/\text{d.p.m. sample wt (kg)})}$$

The results (Table 1) show that the sample blanks (reagents + foil) contribute 25–98% of the signals detected, resulting in uncertainties (by standard propagation of errors) of 2–80% for the final ²³²Th data.

The ²³²Th profile (Fig. 3) shows increasing concentrations with depth down to a maximum at 70 m, which coincides approximately with the base of the mixed layer defined by the temperature and salinity profiles. A weak suggestion of a

minimum is found at ~600–900 m. From 1,200 m to the bottom, the water column is very weakly stratified and there is no systematic trend of the ^{232}Th concentration with depth.

Many of the earlier reports of the ^{232}Th concentration in seawater acknowledged large uncertainties caused by the possibility of sample contamination and the large blank corrections that were necessary. Because all of our analyses of deeper samples (>200 m) showed consistently low concentrations (Table 1), we are confident that the much higher values we report for the upper 200 m accurately represent the concentrations in those samples. Our 10-m value is close to the upper limit of 17 d.p.m./ 10^6 kg for surface seawater set by Kaufman¹⁷ and later confirmed by Knauss *et al.*¹⁸. It is also within the range of 10–20 d.p.m./ 10^6 kg recently measured by Moore¹⁹ in surface seawater samples from the eastern Pacific. The one previously reported²⁰ value for surface Caribbean water (160 d.p.m./ 10^6 kg) is almost certainly too high.

The concentrations of ^{232}Th measured in the subsurface maximum are considerably higher than the upper limit for surface seawater given in earlier work. Whether these high concentrations are due to vertical particulate transport of ^{232}Th and its release at the depth of the maximum, or whether they are due to advective transport from a remote source, cannot be decided without additional data. During an earlier occupation of the same station, a ^{210}Pb maximum was found at nearly the same depth²¹.

Our deep-water values are considerably lower than most all others previously reported^{13,18–20,22,23}. The 14 samples from 397 to 4,782 m gave a mean concentration of 2.7 d.p.m./ 10^6 kg and a standard deviation of 1.4 d.p.m./ 10^6 kg. The results were close to our detection limit and could not be determined with very good precision. Improvement of precision at these very low concentrations would require larger samples or a reduction of the Al foil blank. The only value of comparably low magnitude that has been reported is the <2 d.p.m./ 10^6 kg determined by Anderson *et al.*²⁴ on a single sample from the deep North Pacific obtained with a moored adsorber. Recently, Nozaki and Horibe¹³, also using moored adsorbers, reported values ranging from 6.6 to 33.0 d.p.m./ 10^6 kg in the bottom 2,000 m at a 5,800-m station in the western North Pacific. Their values showed a regular decreasing trend with height above the bottom, suggesting a bottom source of ^{232}Th . We have not observed evidence for this in the Caribbean, where the deep water is well mixed.

Fig. 3 Water-column ^{232}Th profile at the Caribbean Sea station (14°31' N, 66°8' W). Also shown are the profiles of potential temperature (θ), salinity (S), and dissolved O_2 .

Although some of the earlier reported ^{232}Th data may be erroneously high because of contamination, it would be premature to reject them before further measurements are made. It may well be that ^{232}Th concentrations in the deep Caribbean are anomalously low by comparison with other regions. The overall pattern of the ^{232}Th distribution, with high concentrations near the surface and low concentrations at depth, is strongly suggestive of control by chemical scavenging in the deep water, and there is evidence that scavenging in the Venezuelan Basin is unusually rapid because of the enclosed nature of the basin and the proportionately large effect of uptake at the boundaries. The residence time of ^{210}Pb in the deep Venezuelan Basin was found to be only 20 yr (ref. 25), compared with values of ~50–200 yr more typical of open-ocean areas^{25,26}. Our unpublished ^{230}Th data obtained by large volume, *in situ* samplers, indicate a Th residence time of ~10 yr in the Venezuelan Basin, compared with open-ocean values of ~20–30 yr (refs 23, 27). Intense scavenging could maintain anomalously low concentrations of ^{232}Th .

The ^{232}Th concentration reported here for filtered seawater samples represents only a small fraction of the total. Our unpublished large volume results for the particulate matter gave an average of 22 d.p.m. $^{232}\text{Th}/10^6$ kg for nine samples collected below 200 m at the same station, or about 90% of the total ^{232}Th . This is in contrast to ^{230}Th , which is generated by decay of dissolved ^{234}U in the water column. Only ~30% of the total ^{230}Th occurs in the particulate form.

The new data reported here, showing the relatively high surface concentrations, raise the question of how dissolved ^{232}Th is supplied to the surface ocean—whether by leaching of dust delivered from the atmosphere or by river input. As discussed by Measures *et al.*²⁸, the question is a generally difficult one for trace metals, and with our limited data we can only advance a few tentative statements regarding the magnitude of the supply that is necessary. From our data, the inventory of dissolved ^{232}Th in the upper 200 m is 6.5 d.p.m. m^{-2} , and from studies of ^{228}Th , it is known that the residence time of dissolved Th in the upper ocean averages ~0.7 yr (ref. 29). Thus a supply rate of 9.3 d.p.m. $\text{m}^{-2} \text{yr}^{-1}$ is required to maintain the inventory of ^{232}Th that we observe. Buat-Menard and Chesselet³⁰ estimated the flux of ^{232}Th in the form of atmospheric dust over the tropical North Atlantic to be 2.2 d.p.m. $\text{m}^{-2} \text{yr}^{-1}$. Because only a small fraction of that flux would be leached on contact with surface seawater, this does not appear to be an adequate source. Moore³¹ reported a value of 0.024 d.p.m. $^{232}\text{Th} \text{kg}^{-1}$ in centrifuged Amazon River water. Taking that value and the river flux to the Atlantic of 250 $\text{kg} \text{m}^{-2} \text{yr}^{-1}$ yields a ^{232}Th flux of 6 d.p.m. $\text{m}^{-2} \text{yr}^{-1}$, not much lower than the required supply rate estimated above. Considering that the Caribbean is probably more affected

by river input than the average Atlantic surface water, river input may be an adequate source of ^{232}Th , although nothing is known about the estuarine behaviour of Th.

We thank Dr Hein DeBaar for collecting the samples on R/V *Knorr*. This work was supported by the NSF (grant OCE83-14706). Contribution no. 5923 from the Woods Hole Oceanographic Institution.

Regressive events in the postnatal development of association projections in the visual cortex

David J. Price & Colin Blakemore

Laboratory of Physiology, University of Oxford,
Parks Road, Oxford OX1 3PT, UK

In newborn kittens, neurones in area 17 of the visual cortex projecting to area 18 are distributed in bands of uniform density across the superficial layers (laminae II, III and the upper part of IV) and the deep layers (V and VI). During weeks 2 and 3 postnatal, the cells of origin of this association pathway become mainly restricted to discrete, dense clusters, ~600 μm from centre to centre, in the upper layers, with intervening zones free of association cells^{1,2}, as in the adult cat^{3,4}. We have used retrogradely transported, long-lasting neuronal markers to investigate this developmental refinement of the pattern of cortico-cortical connections. The results, reported here, indicate that axonal retraction plays a significant part in the maturation of the clustered organization of superficial layer neurones projecting to area 18, but that cell death may also be a factor in the elimination of the inappropriate projection from the deep laminae.

Recent research has demonstrated that certain neurones in the mammalian cerebral cortex, early in development, have axonal connections to targets that would be inappropriate in the adult animal. For the long interhemispheric and cortico-spinal pathways, the postnatal elimination of these initially 'exuberant' projections seems to be achieved by axon retraction without death of the cells of origin^{5,6}. Neuronal death certainly occurs in many parts of the developing nervous system⁶, including during the early stages of formation of the cerebral cortex⁷, but it has not yet been shown to be involved in the elimination

Fig. 1 Analysis of LGN cells retrogradely labelled following an injection of WGA-HRP into area 18 in a 4-day-old kitten. *a*, Dark-field illuminated coronal section through the thalamus, showing labelled cells lying in a central position in the LGN, as well as in the medial interlaminar nucleus (MIN). The lateral and ventral borders of the LGN are indicated by the broken line. Scale bar, 1 mm. *b*, Histogram of cross-sectional areas of a sample of cells from the middle of the region of uptake. Solid blocks represent labelled cells; mean values (in μm^2) are indicated for total (open arrow) and labelled (solid arrow) samples. Injections that produced labelling of relatively large, centrally placed cells in the LGN were considered to be confined to area 18.

of exuberant cortical projections. In the present study we examined the factors involved in development of the relatively short cortico-cortical projections from area 17 to area 18 in kittens.

Kittens were anaesthetized with halothane, fixed in a stereotaxic holder⁸ and axonally transported tracers were injected into area 18 of the visual cortex. Three animals, two aged 2 days and the third aged 2 months, were given a single 500 nl injection of a 2% solution of the fluorescent tracer fast blue (FB) via a pulsatile pressure system through a glass micropipette (tip diameter ~50 μm) into area 18 on the left side of the brain. These kittens then survived for 4 weeks before perfusion with a 4% solution of paraformaldehyde. In one of these animals the initial injection of FB at 2 days was followed at 1 month old, 24 h before perfusion, by a second injection of diamidino yellow (DY; see ref. 9) into area 18 close to the original FB injection site, using identical methods. In a further four kittens (aged 1, 4, 10 and 20 days) area 18 was injected iontophoretically (repetitive positive current pulses of 3 μA for 2 h) with a 10% solution of horseradish peroxidase conjugated with wheat-germ agglutinin (WGA-HRP) dissolved in a solution of Tris(hydroxymethyl)methylamine; these animals were perfused either 8 or 24 h later with 1.25% glutaraldehyde and 1% paraformaldehyde.

Coronal sections 50 μm thick were cut through the visual cortex and lateral geniculate nucleus (LGN) on the side of the injection; material containing WGA-HRP was reacted using tetramethylbenzidine as the chromogen¹⁰ and counterstained with neutral red. Sections were examined using light or fluorescence microscopy and drawings were made of the positions of all labelled, or, where appropriate, double-labelled cells, within the cortex and LGN. For each animal a series of sections through the visual cortical areas was counterstained with cresyl violet and another was reacted to reveal cytochrome oxidase activity¹¹. We made high-power drawings of the outlines of all labelled cells (in which the nucleus and nucleolus were visible) within an area in the centre of retrograde labelling in the LGN, and the cross-sectional areas of these cells were calculated using a graphics tablet linked to a computer. The sizes of these labelled cells were compared with those of a sample of intermingled unlabelled Nissl-stained LGN neurones from within the same area.

The injection sites of FB and DY in area 18 were all ~1 mm wide but covered the entire depth of the cortex so as to expose axon terminals in all laminae to the tracer. Haloes of staining around the deposits of WGA-HRP were slightly larger and more variable in size (up to 2 mm wide), although the effective uptake sites of WGA-HRP¹⁰, estimated from the pattern of label in the

Fig. 2 Photomicrographs of area 17, showing labelling of neurones with FB or WGA-HRP after injections into area 18. *a*, At 8 h after injection of a 4-day-old kitten with WGA-HRP, showing labelled cells lying in continuous bands in the superficial and deep layers; *b*, 24 h after injection of a 20-day-old kitten with WGA-HRP in which labelled cells lie in patches mainly in the upper layers; *c*, 4 weeks after injection of a 2-day-old kitten with FB, showing persistent continuous bands of labelled cells that are much denser in superficial than in deep layers; *d*, 4 weeks after injection of a 2-month-old kitten with FB, showing clusters of labelled cells mainly in the superficial layers, with few in the deep layers. *a*, *b*, Dark-field-illuminated; *c*, *d*, fluorescence photomicrographs. Artefactual label is seen along the pial surface in *a* and *b*, and white arrowheads in *b* indicate radial blood vessels. Scale bar, 1 mm.

LGN, were probably less than 2 mm across. The positions of injection sites relative to the borders of area 18 were determined not only by direct examination of the cytoarchitectonics¹² and cytochrome oxidase activity¹³ of the surrounding cortex, but also by inspection of the distribution and size of labelled cells in the LGN. In all animals the group of labelled cells lay in the centre of the LGN (Fig. 1*a*) in the coronal plane, not extending to either the medial or lateral edges of the nucleus, and the average cross-sectional area of these neurones was considerably larger than the mean size of cells sampled from the total population in the same region of the nucleus (Fig. 1*b*), indicating that, in every case, a central portion of the width of area 18 had been successfully injected without involvement of area 17 or 19 (ref. 14).

Tracers were transported to the cell bodies of association neurones in a topographically corresponding part of area 17, in

Fig. 3 Camera lucida drawing of a single coronal section through areas 17 and 18 of a 30-day-old kitten that had been injected with FB on day 2 and with DY on day 29. The FB injection site (cross-hatched) overlaps with the DY injection site (unshaded). FB-labelled cells in area 17 are found in two continuous bands (cross-hatched) in the superficial layers and, with lower density, in the deep layers, but DY-labelled cells lie in distinct clusters (dotted), mainly in superficial layers. Where these patches overlap with the band of FB-labelled cells, a number of the DY-labelled cells also contained FB. Areal boundaries were defined on the basis of Nissl- and cytochrome oxidase-stained material; cortical lamination is also indicated.

the same coronal plane as the injection site (Fig. 3); the position of this region of labelling provided yet more evidence that the injections had been placed in the body of area 18. The fact that a region of cortex between the injection and uptake sites contained no labelled cells (Fig. 3) indicated that tracer had not spread directly through the cortex to label neurones in area 17. Invasion of the white matter by diffused tracer around each injection site was slight and, in any case, the pattern of uptake in area 17 was different from that observed when white matter is deliberately injected².

In the kitten that was injected with FB at 2 months old and allowed to survive for 4 weeks, and in the 3-week kitten injected with WGA-HRP and perfused after 24 h (Fig. 2*d*, *b*), tracer was transported into dense clusters of cells in area 17 of ~300 μ m diameter, separated by virtually label-free zones ~300 μ m wide (Table 1 shows average cell densities in the middle of clusters in sections 50- μ m thick). Just as in adult cats, most of the labelled neurones were in the upper cortical layers, with small numbers (one-fifth or less of the density of cells in the upper layers) lying in radially aligned sparse clusters in the lower layers (Table 1). The similarity in the patterns of labelling in area 17 in these two animals suggests that FB was not substantially metabolized and hence lost from cells during the weeks after an injection, nor did it spread widely to label distant cells. Previous workers have demonstrated that FB can remain for long periods within the cytoplasm of a neurone without obvious signs of damage or leakage across the cell membrane: even after several weeks, uptake by neighbouring cells (usually glial cells) is slight^{5,15}. We also saw occasional, very faintly stained cells near neurones that were heavily labelled with FB, but they were small in number, easily distinguished and were not included in our counts of labelled cells.

In younger kittens, aged 1, 4 and 10 days, that had been injected with WGA-HRP and perfused soon afterwards (8 h), the picture was quite different (Fig. 2*a*): there were two continuous bands of labelled cells of uniform density in area 17 in the 1- and 4-day animals, and in most sections from the 10-day

Table 1 Average densities of labelled cells (mm^{-2} , in sections $50\ \mu\text{m}$ thick) in superficial and deep layers of area 17 after injections of tracers into area 18

	Injections followed by short (8 or 24 h) survival					Injections followed by long survival		
	Age at injection (days)					Age at injection		
Cell density in superficial layers	1	4	10	20	29	2 days	2 days	2 months
	170 (21)	462 (43)	239 (14)	363* (27)	390† (23)	331 (18)	375 (25)	382* (23)
Cell density in deep layers	209 (25)	210 (28)	191 (14)	52* (16)	55† (12)	81 (12)	69 (19)	74* (11)
Ratios of densities (superficial/deep)	0.8	2.2	1.3	7.0	7.1	4.1	5.4	5.2

Values are means (with s.e.m. in parentheses). In each of the animals in which labelled cells were distributed in non-patchy bands (that is, kittens injected at 1, 2, 4 and 10 days), 10 consecutive sections ($50\ \mu\text{m}$ thick) through the centre of the area of uptake were selected and the cell density calculated in the upper and lower layers between two lines, 1–1.5 mm apart, drawn parallel to the radial palisades of cortical cells at the point where the density of labelled cells began obviously to decline towards the edge of the area of uptake. In those kittens in which a patchy distribution was seen, densities were measured within a number (* $n=15$; † $n=10$) of corresponding clusters in both superficial and deep layers from several sections covering the centre of the region of uptake. The ratios of the density in superficial layers to the density in deep layers are shown, and lie between 0.8 and 2.2 for all animals aged ≤ 10 days but are much higher in all kittens older than this at the time of perfusion, regardless of the age of injection.

animal. One band lay in superficial layers and the other band, of similar density, in deep layers (densities are shown in Table 1). In the youngest animals, the density of labelled cells was quite constant along each band and labelled cells were not scattered outside the area topographically related in position to the injection site. These facts argue strongly against the possibility that uptake of tracer by axons of passage in the cortex or the white matter had led to the aberrant pattern of labelling in area 17 in young kittens. In some sections from the 10-day-old animal there was evidence of patchiness in the distribution of labelled cells within the superficial and deep layers as the characteristic clustering of the association cells began to appear^{1,2}.

In the two 30-day-old animals that had been injected with FB on postnatal day 2, there was a non-patchy distribution of labelled cells in both superficial and deep layers in area 17 (Fig. 2c), although the density of labelled cells was markedly reduced in the deep layers (Table 1).

Thus, when a long-lasting tracer is injected into area 18 soon after birth, the pattern of label persisting in both superficial and deep layers of area 17 at a much later age remains non-patchy, as in the newborn kitten, despite the fact that the association projection has by this stage actually matured to its typical adult-like patchy form. When DY was injected into area 18 24 h before perfusion in a 29-day-old animal that had previously been injected with FB on day 2, a patchy pattern of DY-labelled cells was seen in addition to the continuous band of FB-labelled neurones in area 17 (Fig. 3). The centre of the DY injection was slightly closer to the 17/18 border than that of the FB injection, and the two stains only partly overlapped each other in area 18. The patches of DY-labelled cells in area 17 were correspondingly displaced towards the 17/18 boundary, compared with the band of FB-labelled neurones. Where the DY patches were superimposed on the continuous FB bands, about one-third of the labelled cells were clearly double-labelled.

As distinct, segregated patches of labelled cells in area 17 were still clearly visible 4 weeks after an injection of FB into a 2-month-old kitten, and since the density of label in 30-day-old animals injected with FB on day 2 was not uniform throughout the depth of the cortex but was virtually absent from the lower half of layer IV (Fig. 2), it is most unlikely that leakage and widespread diffusion of FB had obscured the appearance of patches in the latter animals.

We conclude that many of the cells in the superficial layers of area 17 (as well as some of those in the deep layers) of the neonatal kitten that initially send association projections survive, even though they lose their connections with area 18 by the third week postnatal, to leave the typical patchy distribution of cortico-cortical cells. Our results (Table 1) provide no evidence

for a net postnatal change in the density of association cells within regions of the upper layers of area 17 that remain connected to area 18, and indicate that wholesale death of association cells probably does not occur within the superficial layers. On the other hand, the density of labelled cells in the deep layers of area 17 was much reduced in older kittens and was very similar whether the injection into area 18 had been made on day 2, with long survival, or after 20 days of age. Thus, the loss of the aberrant early projection from the infra-granular layers may partly result from cell death. The marked reduction in cell density in deep layers relative to superficial layers (Table 1) cannot be explained by differential growth of the cortex. First, these observations were all made on the relatively flat portion of area 17, in the medial bank of the lateral gyrus, where areal expansion should stretch all layers roughly equally: in any case, direct measurement of the dimensions of the medial bank of the lateral gyrus suggests that this part of area 17 expands in surface area by only ~15% between days 10 and 20, during which period there is a fourfold or greater fall in the density of labelled cells in the lower layers (Table 1). Measurement of cortical layers II, III and upper IV shows that they actually increase in thickness (by 38% on average) more than do layers V and VI (by 25%) over the first 4 weeks postnatal. Wholesale migration of association neurones from deep to superficial layers is not excluded but is unlikely as very few labelled cells were ever seen in lower layer IV. On balance, our results are most parsimoniously explained by the death of aberrant association neurones in the deep layers.

The cortico-cortical projection from area 17 to area 18 is present and topographically arranged at birth, before the onset of visual stimulation, and is highly exuberant, much of it originating from aberrant populations of cortical neurones. Axonal retraction and cell death both appear to have major roles in the postnatal refinement of this projection, the former leading to the typical clusters of association cells in the upper layers, the latter contributing to the substantial reduction of the projection from the lower layers.

We thank Karen Wenk-Salamone for help with the histology, and the MRC for support; D.J.P. is an MRC Training Fellow and the experiments were funded from MRC programme grants (G979/49 and G7900491) to C.B.

Ultrastructural localization of choline acetyltransferase in vascular endothelial cells in rat brain

J. G. Parnavelas, W. Kelly & G. Burnstock

Department of Anatomy and Embryology and Centre for Neuroscience, University College London, Gower Street, London WC1E 6BT, UK

Furchgott and Zawadzki¹ have shown that acetylcholine (ACh) does not act directly on the smooth muscle of blood vessel walls, but rather via receptors on the endothelial cells lining the lumen, to release an endothelium-derived relaxing factor (EDRF). As it is very unlikely that neurotransmitter released from the periaxillary nerves, which are confined to the adventitial-medial border, diffuses all the way through the medial muscle coat before acting on endothelial cells to release EDRF to produce vasodilatation, this discovery has been regarded as an indication of a pathophysiological mechanism, rather than a physiological one (see refs 2, 3). ACh is rapidly degraded in the blood by acetylcholinesterase, so that ACh must be released locally to be effective on endothelial cells. Here we demonstrate the immunocytochemical localization of choline acetyltransferase in endothelial cells of small brain vessels, which is consistent with the view that the ACh originates from endothelial cells that can synthesize and store it. We suggest that release of ACh following damage to endothelial cells during ischaemia contributes to a pathophysiological mechanism of vasodilatation which protects that segment of vessel from further damage as well as brain cells from hypoxia.

The source of local ACh that might be involved in pathophysiological vasodilatation via endothelial cells is problematical, and it is this aspect that has been examined in the present

investigation of vessels of the brain, where potent ACh-induced vasodilatation has been shown to be dependent on the presence of intact endothelial cells⁴.

Eight adult Wistar rats were anaesthetized with ether and perfused via a cannula tied into the ascending aorta with 200 ml of fixative containing 4% paraformaldehyde, 0.1% glutaraldehyde, 0.1 M lysine-HCl and 0.01 M sodium periodate in 0.1 M phosphate buffer, pH 7.3. This was immediately followed by 500 ml of the same fixative without glutaraldehyde. The brains were removed and placed in fixative for 2 h, then transferred to 0.1 M phosphate buffer and stored overnight at 4 °C. Coronal sections through the visual cortex were cut at 50 µm using a Vibratome and collected in 0.1 M Tris buffer. Sections were processed for immunocytochemical staining of choline acetyltransferase (ChAT) using a recently derived rat monoclonal antibody against ChAT prepared and tested for specificity as described previously^{5,6}. Following treatment with 3,3'-diaminobenzidine and hydrogen peroxide, sections were transferred to 1% OsO₄ for 30 min, stained with 1% aqueous uranyl acetate, dehydrated through an ethanol series and embedded in Araldite. Preincubation of the antiserum with purified ChAT has been shown to abolish cortical staining⁷. In sections from two control rats the primary antibody or the rabbit anti-rat IgG were omitted, resulting in elimination of positive staining in the peroxidase-antiperoxidase procedure.

Examination of the sections under the light microscope and of numerous ultrathin sections from all experimental animals with the electron microscope showed that a small percentage (~10%) of endothelial cells of cortical capillaries and small blood vessels contained ChAT immunoreactivity (Fig. 1). This immunoreactivity was confined to the cytoplasm. Because of the dark nature of the reaction product, organelles present in the cytoplasm could not be discerned, except for mitochondria which appeared to be clustered near the nucleus (Fig. 1c). The relatively small number of labelled endothelial cells may indicate that the levels of ChAT are too low to be detected in some cells and/or that a small proportion of cells containing ACh is sufficient to activate neighbouring cells to release EDRF. ChAT immunoreactivity was also localized in nonpyramidal neurones primarily of the bipolar variety, in agreement with previous findings^{8,9}. Occasionally the dendrites of these neurones, as well as ChAT-stained axons, appeared to be in close association with blood vessels.

The finding that ChAT is localized in vascular endothelial cells in the brain prompts the speculation that choline is taken

Fig. 1 *a*, Longitudinal section through part of a capillary in the upper layers of the rat visual cortex. The wall of the capillary comprises a ChAT-labelled endothelial cell (*) and a process (arrows) of an unlabelled endothelial cell from the same capillary. *b*, Unlabelled endothelial cell from the same capillary. *c*, The labelled cell shows a clear nucleus (Nuc) and thin perinuclear cytoplasm containing a few organelles and a cluster of mitochondria. *a*, *b*, $\times 5,830$; *c*, $\times 15,770$.

up by endothelial cells and converted in the presence of ChAT to be stored as ACh; any local damage to these cells would result in release of ACh and vasodilatation resulting from relaxation of the smooth muscle and/or endothelial cell processes (see ref. 10). Such local vasodilatation mediated by ACh released from damaged endothelial cells would provide protection from further damage in this region of the vascular bed and would protect brain cells from hypoxia.

The number of endothelial cells that contain ChAT in different vascular beds and vessels, and within particular vessels in any one bed, is currently being studied. Preliminary studies have revealed ChAT immunoreactivity in endothelial cells of mesenteric arteries of the rat, but it will be necessary to study ChAT localization in some larger vessels, such as the rabbit thoracic aorta, the tissue that Furchgott used when making the original observations, before it can be claimed that local synthesis, storage and release of ACh from endothelial cells is the universal

mechanism for ACh endothelial cell-mediated vasodilatation. It will also be important to determine how far the ACh released from endothelial cells is conveyed to other parts of the vasculature before being inactivated.

We thank Eva Franke for technical assistance. This work was supported by MRC Project Grant G8312953N. We thank Dr F. Eckenstein for making available the anti-ChAT antibody.

The joining together of neurites to form fascicles and the growth of axons along glial surfaces^{1,2} during early development suggest that neurone-neurone and neurone-glial adhesion interactions are of considerable importance for defining nerve tracts. *In vitro* studies have indicated that adhesion between neurones³⁻⁵ involves a glycoprotein that has been independently studied under the names of N-CAM (for neural cell adhesion molecule⁶⁻⁸), D2-CAM⁹ and BSP-2 (refs 10, 11). As N-CAM/D2-CAM appears to be a homophilic ligand¹² that binds to N-CAM/D2-CAM polypeptide on adjacent cells, this glycoprotein is potentially important in adhesion interactions between any two N-CAM/D2-CAM-expressing cells. While it has been suggested that neurone-glial adhesion involves molecules other than N-CAM/D2-CAM¹³⁻¹⁵, it is known that N-CAM/D2-CAM antigenic determinants are expressed by glial cells *in vivo*^{16,17} and that injection of anti-N-CAM antibodies into the eye-cup of chick embryos disrupts normal patterns of neuritic apposition to glial endfeet in the developing optic stalk¹⁷. Do the molecules expressed by glia share restricted antigenic determinants, or binding domains, with N-CAM/D2-CAM, or are N-CAM/D2-CAM polypeptides expressed by glia? Here we present immunocytochemical evidence which suggests that all classes of macroglia express N-CAM/D2-CAM antigenic determinants on their surfaces and immunochemical analyses which indicate that the molecules expressed by purified astrocytes are closely similar, or identical, to at least some forms of N-CAM/D2-CAM obtained from whole brain or purified neurones. However, our results also suggest that different N-CAM/D2-CAM polypeptides may be separately expressed by neurones and astrocytes.

Expression of N-CAM/D2-CAM antigenic determinants was examined in cultures of all classes of central nervous system (CNS) macroglia that can be identified with cell-type specific antibodies and on Schwann cells, the glial cells of the peripheral

Fig. 1 *a*, Comparison of the anti-D2-CAM (lane 2), anti-N-CAM (lane 3) and anti-BSP-2 (lane 1) antisera in terms of the antigens immunoprecipitated by each from rat brain membranes indicates that all three antisera extract the same three polypeptides from brain. Bars represent the positions of standard markers of M_r : 200,000, 100,000, 69,000, 46,000 and 31,000. *b*, Antibody specificities were compared by crossed immunoelectrophoresis with intermediate gel. The intermediate gel contained no antiserum (left), anti-BSP-2 antiserum (middle) and anti-N-CAM antiserum (right).

Methods. *a*, Anti-D2-CAM antiserum is described in ref. 30 and anti-BSP-2 in ref. 27; anti-N-CAM antiserum was produced by injecting a rabbit with three intraperitoneal injections of 50 μ g of purified mouse N-CAM (purified by affinity chromatography using a monoclonal antibody specific for N-CAM carbohydrate structures²⁵) in Freund's complete adjuvant at 3-week intervals (M.W. and U.R., unpublished). Membranes (from 25-day-old animals) were labelled with ¹²⁵I by the chloramine-T method⁴⁵. Iodinated membranes were solubilized in Tris-barbitol buffer (0.07 M Tris, pH 8.6) containing 4% Triton X-100, 0.2 mM phenylmethylsulphonyl fluoride and 100 U ml⁻¹ aprotinin for 60 min on ice. After centrifugation at 10,000g for 15 min, the supernatants were submitted to crossed electrophoresis⁴⁶ with anti-BSP-2 (lane 1), anti-D2-CAM (lane 2) or anti-N-CAM (lane 3) antibody in the second-dimension gel. Immunoprecipitates were solubilized by boiling for 5 min in buffer containing 2% w/v SDS and 5% v/v 2-mercaptoethanol and analysed by SDS-polyacrylamide gel electrophoresis on 4-20% gradient gels⁴⁷. Gels were dried and fixed for autoradiography on Kodak X-Omat film at -70 °C. *b*, For crossed immunoelectrophoresis⁴⁸, Triton X-100 solubilized rat brain membranes were submitted to crossed immunoelectrophoresis against anti-D2-CAM antiserum. An intermediate gel was included containing the following antisera: (left) no antiserum, (middle) anti-BSP-2 antiserum, and (right) anti-N-CAM antiserum. After electrophoresis the plates were stained for protein with Coomassie stain. Anti-BSP-2 and anti-N-CAM antibodies retracted the D2-CAM immunoprecipitates into the intermediate gel, demonstrating that they recognize the D2-CAM antigen(s).

Fig. 2 N-CAM/D2-CAM antigenic determinants are expressed by astrocytes and Schwann cells. *a-c*, Living cultures of purified type 1 astrocytes^{18,19} grown on poly-L-lysine-coated glass coverslips were incubated first with H28 monoclonal antibody (hybridoma supernatant, undiluted), and then with biotin-conjugated goat anti-rat immunoglobulin (Amersham, 1:100), and fluorescein-conjugated streptavidin (Amersham, 1:100). Cultures were then fixed with methanol (-20°C , 10 min) and stained with rabbit anti-glial fibrillary acidic protein (GFAP) antiserum⁴⁹ (1:2,000), followed by rhodamine-conjugated goat anti-rabbit immunoglobulin (R1g-Rd). Identical staining patterns for N-CAM/D2-CAM were obtained by staining the mouse cultures, or similar rat astrocyte cultures, with rabbit anti-N-CAM, anti-D2-CAM or anti-BSP-2 antisera, followed by labelling with goat anti-R1g-Rd. *a*, Phase contrast; *b*, anti-GFAP; *c*, H28 anti-N-CAM. *d-f*, Control staining for *a-c*. H28 antibody was not included in the antibody incubations. *g-i*, Schwann cells from the sciatic nerves of neonatal mice were examined with H28 antibody and with rabbit anti-N-CAM, D2-CAM or BSP-2 antisera. Cultures were labelled as for *a-f*, except that rabbit anti-P₀ antiserum was used in place of rabbit anti-GFAP. N-CAM/D2-CAM antigenic determinants were expressed by many Schwann cells; however, most Schwann cells which had expressed the myelin protein P₀ did not co-express N-CAM/D2-CAM. *g*, Phase contrast; *h*, anti-P₀; *i*, H28. Labelling conditions and analysis of cultures as in refs 18–20. Serum from nonimmune rabbits did not label the surface of astrocytes or Schwann cells, and none of the conjugates used reacted with antibodies from inappropriate species or labelled cells in the absence of anti-N-CAM/D2-CAM or cell-type-specific antibodies.

nervous system. Purified astrocytes from rat and mouse cerebral cortex were prepared according to published procedures^{18,19}. These cultures contained 95–98% type 1 astrocytes²⁴—that is, 95–98% of the cells were labelled with antiserum against glial fibrillary acidic protein (GFAP), a cell-type specific marker of astrocytes²¹, but did not label with the monoclonal antibody A2B5 (ref. 22). These cultures contained no other classes of macroglia, and no neurones (see refs 18, 19). The small proportion of contaminating cells were fibroblast-like cells that expressed cell-surface fibronectin, but did not express GFAP. All immunolabelling and immunochemical experiments were carried out on astrocyte cultures of this kind. In addition, experiments involving biosynthetic labelling or immunochemical quantification were repeated on astrocyte cultures that were prepared by other methods²³ and grown for 3–4 weeks in Dulbecco's modified Eagle's medium containing 10% v/v heat-inactivated horse serum. The two types of astrocyte cultures produced identical results in these experiments. Expression of N-CAM/D2-CAM determinants by other CNS glia was examined in cultures of optic nerves from embryonic chicks and neonatal rats and mice, and expression of these determinants by Schwann cells was examined in enriched Schwann cell cultures prepared from sciatic nerves of neonatal mice (as in ref. 24).

Cultures were examined with three separate rabbit antisera (anti-N-CAM, anti-D2-CAM and anti-BSP-2, see Fig. 1) against the N-CAM/D2-CAM polypeptides, with a monoclonal antibody directed against chick N-CAM²⁵ and the H28 monoclonal antibody directed against mouse N-CAM^{11,26}. N-CAM/D2-CAM is expressed in multiple forms that differ in their carbohydrate composition^{6–8,10} and the size of their cytoplasmic domains²⁷, but that are thought to be otherwise identical^{27,28}. In post-embryonic brain the three dominant forms of this molecule have relative molecular masses (M_r) of 120,000, 140,000 and 180,000 (or 200,000, depending on the gel system used)^{26,29,30}. The three rabbit antisera used in our studies immunoprecipitate all three of these polypeptides from rat brain extract (Fig. 1*a*), both anti-N-CAM and anti-BSP-2 antisera react with the D2-CAM antigens (Fig. 1*b*), and all reactivity of N-CAM/D2-CAM antigen(s) with anti-D2-CAM antisera could be removed from extracts of rat brain by preabsorption with anti-N-CAM or anti-BSP-2 antisera (not shown). Thus, it appears that these three antisera are all directed against identical N-CAM/D2-CAM polypeptides. Both monoclonal antibodies have been previously characterized as recognizing protein determinants specific for the N-CAM/D2-CAM polypeptides^{25,31}.

Using immunofluorescence microscopy, all classes of glia examined were found to express N-CAM/D2-CAM determinants. In cultures of purified type 1 astrocytes from rat cerebral cortex, all of the GFAP⁺ astrocytes were labelled by all three rabbit antisera; purified type 1 astrocytes from mice were similarly labelled, and were also labelled by the H28 monoclonal anti-N-CAM antibody (Fig. 2). In cultures of optic nerve from neonatal rats, examined 1 and 3 days after preparation of the cultures, the rabbit antisera labelled cells possessing the antigenic and morphological phenotypes of oligodendrocytes, type 2 astrocytes, oligodendrocyte-type 2 astrocyte (O-2A) progenitors^{20,32} and type 1 astrocytes (not shown). Cells in cultures of mouse optic nerve were similarly labelled and were labelled by the H28 monoclonal anti-N-CAM antibody (not shown). In cultures of chick optic nerve, the majority of cells were labelled with monoclonal anti-chick-N-CAM antibody (not shown). As optic nerve cultures contain no neurones³², these results suggest that N-CAM/D2-CAM determinants are expressed by all of the major classes of CNS macroglia which can be identified by cell-type specific antibodies, and that these determinants are either expressed *in vivo* or are expressed within 24 h of growth *in vitro*. In addition, in cultures of enriched mouse Schwann cells from sciatic nerves of 3–7-day-old mice (prepared as in ref. 24), we found labelling of some, but not all, cells with the morphology typical of Schwann cells (Fig. 2). In double-labelling experiments using rabbit antiserum against the myelin protein P₀, which labels Schwann cells that have been induced to synthesize myelin-specific proteins³³, many of the P₀⁺ Schwann cells were not labelled by any of the rabbit anti-N-CAM/D2-CAM antisera, or by the H28 monoclonal antibody. Some double-positive cells were present in the cultures, but the majority of N-CAM/D2-CAM⁺ cells with Schwann-cell like morphologies were P₀[−]. Loss of expression of N-CAM/D2-CAM antigenic determinants by myelinating Schwann cells has been seen *in vivo*³⁴, and a comparable loss of N-CAM/D2-CAM expression by older oligodendrocytes has also occasionally been seen *in vitro* (M.N. and I. Sommer, independent unpublished observations). In cultures of sciatic nerve that had not been treated to enrich for Schwann cells, a small proportion (<20%) of cells with fibroblastic morphology were lightly labelled by the H28 monoclonal anti-N-CAM/D2-CAM antibody, but most fibroblast-like cells in these cultures were N-CAM/D2-CAM[−].

Immunofluorescence analyses further support the view that the determinants recognized by indirect immunofluorescence, at least on Type 1 astrocytes, represent N-CAM/D2-CAM. (1) Immunoblots of astrocyte extracts with both anti-N-CAM and

Fig. 3 *a*, SDS-gel electrophoresis of 7-day neonatal mouse brain (1), rat retina (2) or cultured astrocytes (3–5) followed by immunoblotting with anti-N-CAM (1–3), anti-D2-CAM (4) or nonimmune (5) antisera. *b*, Immunoprecipitation of N-CAM/D2-CAM polypeptides from astrocytes and neurones radiolabelled *in vitro* with ^{35}S -methionine. Lane 1, astrocyte cultures; lane 2, cerebellar neurone cultures. *a*, Purified astrocytes were scraped off the surface of Falcon flasks (no. 3024) on ice and centrifuged at 500g for 10 min at 4°C. The cell pellet, or brain tissue, was solubilized in an equal volume of extraction buffer containing 2% SDS and 5% 2-mercaptoethanol, subjected to electrophoresis in 7.5% acrylamide gels, and transferred to nitrocellulose sheets³⁰. N-CAM/D2-CAM was visualized by reaction with the appropriate antiserum followed by horseradish peroxidase-conjugated goat anti-rabbit IgG and staining by treatment with 4-chloro-1-naphthol³¹. M_r s in SDS are based on the migration of myosin, phosphorylase *b*, bovine serum albumin and ovalbumin. Staining is seen of material of M_r 140,000, with very light staining of material of M_r 120,000. *b*, Cultures were labelled with 500 μCi of ^{35}S -methionine (NEN) for a 30-min labelling period, followed by a 30-min chase. Cells were collected, solubilized with Triton X-100 and N-CAM/D2-CAM antigens were immuno-isolated by immunoelectrophoresis against anti-D2-CAM antiserum³⁸. Cultures of cerebellar neurones were established from 8-day-old rats as described by Meier and Schousboe⁵², except that the medium contained 10% v/v horse serum instead of fetal calf serum. After 2 weeks the cultures were labelled with ^{35}S -methionine as described for astrocyte cultures, except that both labelling and chase periods were of 60 min duration. Cells were collected and D2-CAM immuno-isolated as above. Immunoprecipitates were further analysed by SDS-polyacrylamide gel electrophoresis as described in Fig. 1a.

anti-D2-CAM antisera recognized a predominant band of M_r 140,000 that migrated in the same position as the 140,000- M_r band from brain. A weak staining was also observed at M_r 120,000, but this did not reproduce well in the photography (Fig. 3a). (2) In a second protocol, astrocytes and purified neurones³⁵ were separately labelled *in vitro* with ^{35}S -methionine, anti-D2-CAM antiserum was used to immunoprecipitate radio-labelled antigens³⁵, and precipitates were analysed on SDS-polyacrylamide gels (Fig. 3b). This procedure yielded two predominant astrocytic polypeptides, one band of M_r ~140,000, which migrated identically with one of the N-CAM/D2-CAM bands isolated from neuronal cultures, and a second band of M_r ~120,000. A faint band of higher relative molecular mass, which in the gel system used in these particular experiments was of M_r ~200,000, was occasionally observed in extracts prepared from purified astrocytes. N-CAM/D2-CAM immuno-isolated from purified neurones in culture (Fig. 3b, see also ref. 35) also consisted of two bands, but these were of M_r 140,000 and 200,000; no band of M_r 120,000 was detected in neuronal extracts. The polypeptide of M_r 200,000 seen in neuronal extracts is the same polypeptide which in other gel systems, such as that used in Fig. 3a, has a M_r of ~180,000. Thus, in most experiments we were only able to identify the three N-CAM/D2-CAM polypeptides typical of whole brain (M_r = 120,000, 140,000 and 180,000–200,000^{26,29,30}) by considering the bands obtained from astrocytes and neurones in combination. The apparent lack of neuronal synthesis of the 200,000- M_r band

of N-CAM/D2-CAM has also been seen in recent *in vivo* studies in which chick retinal ganglion neurones have been found to transport N-CAM/D2-CAM polypeptides of M_r 140,000 and 180,000, but not of M_r 120,000, along the optic nerve (J. A. Gardner, M.W. and U.R., manuscript in preparation). There is evidence to suggest that different bands of N-CAM/D2-CAM might be transcribed from different messenger RNAs³⁶; it will now be of interest to compare the details of N-CAM/D2-CAM structure, synthesis and processing in neurones and astrocytes.

From the present studies we conclude that glial cells express N-CAM/D2-CAM antigenic determinants on their surfaces, and that purified type 1 astrocytes grown *in vitro* synthesize N-CAM/D2-CAM-like polypeptides. The astroglial molecules we have examined appear to be closely related to N-CAM/D2-CAM polypeptides characterized in extracts of whole brain, and are probably not related to two other putative cell adhesion molecules from the central nervous system, Ng-CAM^{13,14} and L1 (ref. 37), which are thought to be expressed by neurones but not by CNS glia. The three N-CAM/D2-CAM polypeptides isolated from whole brain are thought to differ primarily in the length of their cytoplasmic domains²⁷, and have previously been found to be almost identical as judged by peptide mapping^{27,28,38}. In contrast, peptide maps of L1 and Ng-CAM are markedly different from those of N-CAM/D2-CAM^{14,39}. L1 and Ng-CAM are also immunochemically distinct from N-CAM, although there may be some shared expression of at least one epitope that has been identified by monoclonal antibodies^{14,40}. Moreover, although L1 has an M_r of ~140,000 and Ng-CAM an M_r of 135,000, which are similar in size to one of the astroglial N-CAM/D2-CAM bands, L1 and Ng-CAM antibodies do not detect material of M_r 120,000, the size of the second major astroglial N-CAM/D2-CAM band.

Although in our present studies we have consistently seen high levels of N-CAM/D2-CAM expression by a variety of glial cell types, previous investigations have suggested that glia do not express N-CAM/D2-CAM *in vitro*^{13,14,26}. We do not yet know the reasons for these differing results; however, it seems likely that expression of N-CAM/D2-CAM by astrocytes can be modulated during development, as appears to be the case for muscle cells^{41,42} and Schwann cells. Nothing is yet known about the regulatory influences that might induce the disappearance of N-CAM/D2-CAM from astrocytes.

The hypothesis that neurones are more adherent to glia than to other neurones or to non-glia has been suggested as providing a cellular explanation for the observations that, both *in vivo* and *in vitro*, growing neurites exhibit a marked affinity for glial surfaces^{18,43,44}. For example, during embryonic development of the optic stalk, neuritic growth cones are found predominantly apposed to endfeet of primitive glia and neuritic fascicles are found organized on these glial surfaces but not on other available surfaces¹. The demonstration of N-CAM/D2-CAM on glial cell surfaces raises the question of whether this molecule is involved in such adhesive interactions between neurones and glia, in distinction from the hypothesis that neurite-neurite adhesion is mediated by N-CAM/D2-CAM and neurone-glial adhesion is separately mediated by Ng-CAM^{14,15}. It has recently been found that N-CAM/D2-CAM antigenic determinants are expressed on glial endfeet in the chick optic stalk and that injection of anti-N-CAM antibody into the eye-cup of chick embryos results, within the optic stalk, in a separation of neuritic fascicles from these glial surfaces¹⁷. Thus, in this particular case, the affinity of neurites for glial surfaces may be due to glial expression of N-CAM/D2-CAM. However, the specific contributions of N-CAM/D2-CAM, Ng-CAM and perhaps other molecules to the generally observed affinity between neurones and glia have yet to be determined.

We thank Jeremy Brockes for the gift of rabbit antiserum against myelin protein P₀. M.N. was supported by a project grant from the MRC and by the International Spinal Research Trust. M.A., C.M., J.L. and E.B. were supported from grants from the Danish MRC (grants 12-4703 and 12-4871), the Lundbeck Foundation, and the 'Kontorchef Svend Coles Frederiksen

and Hustrus Fond'. C.G. was supported by grants from the Ministère de la Recherche et de l'Industrie (82.E.0124) and Centre National de la Recherche Scientifique (ATP 7071/72 and 7071/273). M.W. and U.R. were supported by US PHS grant HD-09635.

Note added in proof: Independent experiments by G. Keilhauer, A. Faissner and M. Schachner (*Nature* 316, 728-730: 1985) have also indicated that purified astrocytes express N-CAM/D2-CAM-like in polypeptides. These experiments also indicate that the binding of neurones to astrocytes *in vitro* can be inhibited by anti-N-CAM/D2-CAM antiserum.

Differential inhibition of neurone-neurone, neurone-astrocyte and astrocyte-astrocyte adhesion by L1, L2 and N-CAM antibodies

Gerhard Keilhauer, Andreas Faissner & Melitta Schachner*

Department of Neurobiology, University of Heidelberg, Im Neuenheimer Feld 504, 6900 Heidelberg, FRG

The cell adhesion molecules L1, N-CAM and Ng-CAM have been implicated in cell-cell interactions among developing neural cells¹⁻⁴. L1 and N-CAM are structurally and functionally distinct molecular entities and act synergistically in mediating Ca²⁺-independent adhesion between re-aggregating early postnatal cerebellar cells⁵. N-CAM has been reported to be neurone-specific in the chicken and to mediate fasciculation of neurites and of nerve-muscle interactions. L1, which in the central nervous system has been found only on post-mitotic neurones, mediates migration of granule cell neurones in the mouse cerebellar cortex⁶. In view of the molecules' distinct effects on cell interactions, we wondered whether different neural cell types are involved in the actions of each molecule. Here we report that L1 antigen promotes neurone-neurone adhesion. N-CAM, which is expressed on both neurones and glia, mediates neurone-neurone, neurone-astrocyte and astrocyte-astrocyte adhesion. The L2 carbohydrate epitope shared between the two adhesion molecules⁷ seems to be involved in neurone-astrocyte and astrocyte-astrocyte adhesion and acts in a more than additive manner in N-CAM-mediated neurone-neurone adhesion.

Homogeneous populations of neurones and astrocytes from early postnatal mouse cerebellum were isolated, probed for expression of adhesion molecules (Figs 1, 2) and used to measure adhesion of single-cell suspensions of probe to monolayer target cells in the absence and presence of Fab fragments (Table 1). In all combinations of probe to target cells (neurone-neurone, neurone-astrocyte, astrocyte-neurone and astrocyte-astrocyte),

Fig. 1 Double immunofluorescence labelling of monolayer cultures from 5-day-old C57BL/6J mouse cerebellum after 2 days *in vitro*. Polyclonal N-CAM antibody (a), prepared as described previously³, reacts with vimentin-positive (b), fibronectin-negative glial cells. Note the patchy distribution of N-CAM on the cell surface (a). c, Phase-contrast micrograph of fluorescence images a and b. Polyclonal N-CAM antibody (d) reacts with an O4 antigen-positive oligodendrocyte (e). f, Phase-contrast micrograph of fluorescence images d and e. Cell culture, cell type-specific markers and double immunofluorescence procedures have been described previously¹⁹. Immunofluorescence labelling of GFAP-positive astrocytes was weaker than that of less differentiated, GFAP-negative, vimentin-positive astrocytes. The tendency for N-CAM to be more strongly expressed on less differentiated glia was also seen with oligodendrocytes: more than 80% of all O4 antigen-positive cells, but only less than 5% of all O1 antigen-positive cells were N-CAM-positive. $\times 300$.

antibodies to liver membranes, which react well with cell surfaces of astrocytes and neurones⁶, did not inhibit adhesion, whereas N-CAM antibodies did. Polyclonal L1 antibodies interfered with neurone-neurone adhesion, but not with neurone-astrocyte or astrocyte-astrocyte adhesion, even when astrocytes from different postnatal ages, from different brain regions or maintained *in vitro* for varying time periods were used. Monoclonal L2 antibodies did not reduce neurone-neurone adhesion, but decreased neurone-astrocyte and astrocyte-astrocyte adhesion. Astrocyte-neurone adhesion resulted in slightly different inhibition values from those seen in the reciprocal combination, as has been observed in other adhesion systems⁸.

Inhibition values obtained with mixtures of polyclonal L1

Fig. 2 Immunoprecipitation of N-CAM from cultures of isolated neurones and astrocytes from early postnatal mouse cerebellum using poly- and monoclonal N-CAM antibodies. **a**, Western blot with polyclonal N-CAM antibody ($10 \mu\text{g ml}^{-1}$ IgG fraction) on crude membrane fraction from adult mouse brain resolved by SDS-polyacrylamide gel electrophoresis (PAGE) on a 6–12% gradient gel⁵. Three bands are seen in the relative molecular mass regions of 180,000 (180K), 140K and 120K. **b–e**, Fluorograph of immunoprecipitates from ³⁵S-methionine-labelled cultures of neurones (**b, d**) and astrocytes (**c, e**) with polyclonal N-CAM (**b, c**) and monoclonal N-CAM antibody H28.123 (**d, e**). Polyclonal and monoclonal antibodies gave identical results. In neurone cultures the antibodies detected two bands of 180K and 140K. In astrocyte cultures two prominent bands in the 140K and 120K range were seen and a fainter band in the 180K range. Note the apparently higher molecular weight of the 180K and 140K forms in astrocytes compared with neurones.

Methods. Cells were obtained and maintained as described in the legend to Table 1. Cultures of 1.5×10^7 cells per 6-cm Petri dish were incubated with $200 \mu\text{Ci } ^{35}\text{S}$ -methionine (Amersham; $1,000 \text{ mCi mmol}^{-1}$) per ml in methionine-free minimal essential medium containing 10 mM HEPES and 2 mM glutamine for 4 h at 37°C.

After two washes with HBSS, cells were solubilized by adding 1 ml of solubilization buffer (150 mM NaCl, 20 mM Tris-HCl, 1 mM EDTA, 1 mM EGTA, 10 mM methionine, 0.5% Nonidet P-40, 0.05% NaN_3 , pH 7.4), the protease inhibitors aprotinin, soybean trypsin inhibitor and turkey egg white trypsin inhibitor (all at $10 \mu\text{g ml}^{-1}$), phenylmethylsulphonyl fluoride and iodoacetamide (both at 5 mM), pepstatin and leupeptin (both at $2 \mu\text{M}$). After 30 min on ice, cells were scraped from the dish, nuclei and debris removed by centrifugation for 10 min at 800g and supernatants cleared for 45 min at 100,000g. For immunoprecipitation, aliquots (1 ml) of the supernatants were incubated with polyclonal N-CAM (150 μg IgG fraction) or monoclonal N-CAM antibody H28.123 (ref. 23; $10 \mu\text{g}$ IgG fraction) for at least 1 h at 4°C. Then 150 μl protein A-Sepharose (10% v/v; Sigma) was added to rabbit IgG and 70 μl of a 10% v/v suspension of Sepharose 4B beads coupled with mouse monoclonal antibody to rat κ -chain²⁴ to monoclonal H28.123 antibody, all in solubilization buffer. After 1 h at 4°C, the beads were centrifuged through a sucrose cushion, washed several times with solubilization buffer and boiled for 4 min at 100°C in 45 μl of SDS-PAGE sample buffer⁵. All steps were carried out at 4°C. Precipitates were analysed by SDS-PAGE on 6–12% gradient gels⁵. Gels were then fixed in 10% acetate, 30% methanol in water and treated with 'amplify' as recommended by the producer (Amersham). Kodak X AR-5 X-ray films were exposed for various times at -70°C and developed according to the supplier's instructions.

and N-CAM antibodies were not additive, indicating that the two adhesion mechanisms are not independent in this adhesion system. In the presence of L2 antibody, polyclonal N-CAM antibodies were more than additive in inhibiting neurone-neurone, but not neurone-astrocyte or astrocyte-astrocyte adhesion. In contrast, inhibition by L2 antibody was unaffected by monoclonal N-CAM antibody, which by itself did not interfere with adhesion (not shown, see also ref. 3). Also, L2 antibody did not increase polyclonal L1 antibody-induced inhibition of neurone-neurone or neurone-astrocyte adhesion (not shown). In the presence of the three antibodies—polyclonal N-CAM and L1 antibodies and monoclonal L2 antibodies (each at a concentration of 1.0 mg ml^{-1})—the inhibition of neurone-neurone adhesion did not exceed the values obtained with N-CAM and L2 antibodies alone. Adhesion of neurones and astrocytes to skin fibroblasts was not reduced by N-CAM, L1 or L2 antibodies, regardless of whether fibroblasts were used as target or probe cells.

Our study has shown that distinct adhesion mechanisms operate between neurones and astrocytes in the mouse cerebellum at the time of postnatal granule cell migration: (1) L1 antigen is involved in neurone-neurone interaction. (2) N-CAM not

only mediates neurone-neurone, but also neurone-astrocyte and astrocyte-astrocyte adhesion. All cell types involved express N-CAM on their surfaces. (3) The L2 domain is involved in an adhesive function that is manifest by itself in neurone-astrocyte and astrocyte-astrocyte and, in conjunction with N-CAM, in neurone-neurone adhesion.

Neurone-glia interaction has been postulated to underlie the migration of granule cell neurones in the early postnatal cerebellum⁹. Because L1 antibodies interfere with migration⁶ and seem to block only neurone-neurone adhesion, it is possible that a prerequisite for migration is an L1-mediated sorting out of post-mitotic granule cell bodies or extension of granule cell axons. On the other hand, it is conceivable, although unlikely, that the cultured neurones and astrocytes used in the present study are not representative of their *in vivo* counterparts. Although L1 antigen shares certain properties with the neurone-neurone and neurone-glia adhesion molecule Ng-CAM^{4,10}, the present study failed to detect the molecular domains involved in neurone-glia adhesion. It is therefore conceivable that the polyclonal L1 and Ng-CAM antibodies recognize different sets of functional sites on L1 antigen from mouse and Ng-CAM from chicken.

Table 1 Inhibition of adhesion between enriched populations of neurones and astrocytes from early postnatal mouse cerebellum in the presence of Fab fragments from L1, N-CAM and L2 antibodies

Antibody	Ref.	Fab concentration (mg ml ⁻¹)	Neurone* to neurone†	Neurone* to astrocyte†	Astrocyte* to astrocyte†	Astrocyte* to neurone†

Single-cell suspensions from early postnatal C57BL/6J mouse cerebella¹⁹ were used for isolation of astrocyte- and neurone-enriched cell populations. Small cerebellar neurones were obtained from 6-8-day-old mice by centrifugation (10 min, 4 °C, 1,200g) through Percoll (Pharmacia, 40.5% in Ca²⁺- and Mg²⁺-free Hank's balanced salt solution (CMF-HBSS) containing 10 mM HEPES and 0.1% bovine serum albumin pH 7.2). The pellet of cells was washed once in basal Eagle's medium with Earle's salts containing 10% horse serum (culture medium) and seeded in poly-L-lysine-coated Costar plates at a density of 1×10^6 in 0.5 ml culture medium per well. Monolayers were used as target cells after 3 days in culture with >99% of all cells expressing N-CAM or L1 antigen and ~60% the L2 epitope. The percentage of glial fibrillary acidic protein (GFAP)- and vimentin-positive astrocytes after 3 days in culture was <1%, compared with 6 ± 2% GFAP-positive and 8 ± 2% GFAP-positive and 8 ± 2% vimentin-positive astrocytes in cultures made from whole cerebellum. Astrocytes were obtained from 3-5-day-old mice by seeding single-cell suspensions into T75 tissue culture flasks (Nunc) at a density of 30×10^6 cells in 10 ml culture medium per flask. After 3 days, cultures were treated with cell-surface-reactive monoclonal antibodies M5 directed against all cerebellar neurones (C. Lagenaur and M.S., in preparation), 04 directed against more and less differentiated oligodendrocytes²⁰, and MESA-1 directed against fibroblast-like cells of endothelial origin²¹ in the presence of guinea pig complement (diluted 1:10). Residual cells were treated with 100 µg ml⁻¹ trypsin, 1 mM EDTA in CMF-HBSS for 5 min at room temperature, centrifuged (5 min, 4 °C, 60g) and seeded in poly-L-lysine-coated Costar plates (10^5 cells in 0.5 ml culture medium per well). Monolayer cultures were used as target cells after 1 day in culture with >97% of all cells expressing GFAP and N-CAM and ~60% the L2 epitope. Fibroblasts were obtained from the skin of 1-day-old mice by treatment with collagenase IV and trypsin²². No significant cell death or proliferation was observed within the culture periods studied. Probe cells were obtained from monolayer cultures of enriched neurones (after 1 day in primary culture), astrocytes (1 day after immunocytolysis and subsequent subculture) and fibroblasts (3 days in primary culture) by treatment with 20 µg ml⁻¹ trypsin, 1 mM EDTA in CMF-HBSS for 15 min at room temperature after three washes with CMF-HBSS containing 1 mM EDTA. To vitally stain the probe cells, fluorescein diacetate (10^{-6} M) was included during the trypsinization step. Trypsinization was stopped by adding 40 µg ml⁻¹ soybean inhibitor and cells were collected by centrifugation (10 min, 40 °C, 60g). Treatment with the low trypsin concentration did not visibly reduce the intensities of immunofluorescence staining with N-CAM, L1, L2 and liver membrane antibodies compared with non-trypsinized cells. Cell concentrations were adjusted to 4×10^5 cells ml⁻¹ CMF-HBSS for neurones, and to 1×10^5 cells ml⁻¹ for astrocytes. Probe and target cells were treated with 0.5 ml Fab fragments of antibodies in CMF-HBSS for 20 min on ice before the adhesion test. Target cells were washed three times with CMF-HBSS containing 1 mM EDTA before addition of Fab fragments. Probe cells (2×10^5 neurones or 0.5×10^5 astrocytes in 0.5 ml) were added to target cells in Costar wells and incubated for 30 min at room temperature in a reciprocal shaker (Infors, Basel, Switzerland) at 40 cycles per min. Unbound probe cells were removed from the monolayer target cells by three gentle washings in CMF-HBSS (1 ml for each well and washing). Aggregation among probe cells was negligible both in controls and in the presence of Fab fragments. Adhering cells were scored by counting ~1,000 cells in >10 microscopic fields at $\times 100$ magnification with an inverted fluorescence microscope (ICM 405, Zeiss). Without Fab fragments the binding of the total input cells was $79 \pm 3\%$ (897 ± 34.0 cells mm⁻²) for neurone-neurone, $82 \pm 2\%$ (931 ± 22.7 cells mm⁻²) for neurone-astrocyte, $47 \pm 4\%$ (133 ± 11.3 cells mm⁻²) for astrocyte-astrocyte, and $49 \pm 2\%$ (138 ± 5.6 cells mm⁻²) for astrocyte-neurone adhesion. Using fibroblasts, $10 \pm 5\%$ binding was seen in all combinations with neurones and astrocytes. Binding of probe cells was predominantly to target cells and not to the cell-free substrate. Each experimental value was run in quadruplicate. Per cent inhibition of adhesion in the presence of Fab fragments was calculated by: % inhibition = [adhesion (control) - adhesion (+Fab)/adhesion (control)] $\times 100$. Numbers are mean values for several experiments $\pm$ s.d. Eight experiments were performed for neurone-neurone and neurone-astrocyte, and four experiments for astrocyte-neurone and astrocyte-astrocyte adhesion. The difference in inhibition of adhesion given by antibody combinations and individual antibodies is significant for the combination polyclonal N-CAM and monoclonal L2 only for neurone-neurone adhesion ($P < 0.001$, Student's *t*-test). Specifications of antibodies and preparations of Fab fragments have been described previously and appropriate references are given. ND, not done.

* Probe cells; † target cells.

N-CAM has previously been detected on glia in addition to neurones (refs 3, 11, 12; see also accompanying paper¹³), although its function in neurone-glia adhesion has remained elusive¹⁰. As N-CAM has been implicated in a homophilic 'self-aggregating' adhesion mechanism¹⁴, it is expected that N-CAM-positive glial cells adhere to other N-CAM-positive cells. In the conditions of our study, we did not observe the synergistic effect between L1 and N-CAM molecules which was seen in re-aggregating cultures of single cells⁵. It is likely that the non-additive effects are the result of different cell dissociating procedures, the lower temperature used to prevent self-aggregation among probe cells, and the anchoring of the target cells at the substrate surface, thereby reducing the molecules' lateral mobility within the membrane and cooperative effects between them.

Adhesion affinities of N-CAM are differentially modulated by the carbohydrate chains of the adult and embryonic forms^{14,15}. It has been suggested that carbohydrate chains are involved in stabilizing the conformation of glycoproteins, and thus indirectly affect their function^{16,17}, or that they are more directly involved as ligands for lectin-like receptors¹⁸. The L2 domain may be yet another, functionally important carbohydrate moiety. The function of the L2 epitope on some but not all N-CAM molecules of the adult and embryonic forms remains to be elucidated in the intact developing nervous system.

We thank C. Lagenaur and V. Künemund for antibodies and advice, C. Goridis for hybridoma clones H28 and MESA-1, L. Eng for antibodies to glial fibrillary acidic protein, W. Franke

for antibodies to vimentin, B. Bizzini for tetanus toxin, H. Bazin for MARK-1 clone, M. Schlotter for production of monoclonal antibodies and Deutsche Forschungsgemeinschaft for support. G.K. is the recipient of a doctoral fellowship from Studienstiftung des Deutschen Volkes.

Muscarinic receptors trigger several different responses including an increase in concentration of cyclic GMP, a decrease in cyclic AMP concentration, breakdown of polyphosphoinositides and changes in ion permeability. It is not yet clear whether these reactions occur sequentially or independently and which directly coupled to the muscarinic receptor. Several lines of evidence indicate that muscarinic receptors in many, if not all, cell types are coupled to the inhibitory guanine nucleotide regulatory protein (N_i or G_i) of adenylate cyclase. To provide direct evidence for this coupling, we have reconstituted muscarinic receptors purified from porcine brain with N_i purified from rat brain in a phospholipid vesicle. Here, we report that the GTPase activity of N_i is stimulated by carbachol. This action is blocked by the simultaneous addition of atropine and is not observed when the N_i protein is ADP-ribosylated. We conclude that one function of the muscarinic receptor is the activation of N_i .

Either the receptor-linked inhibition of membrane adenylate cyclase or the decrease in cellular cAMP is reversed¹⁻³ by islet-activating protein (IAP, pertussis toxin⁴⁻⁶), which abolishes the function of N_i ^{2,7-9} as a result of ADP-ribosylation of the protein^{10,11}. Guanine nucleotides also markedly reduce the apparent affinity of membrane receptors for agonists but not for antagonists¹²⁻¹⁵, and the effect of guanine nucleotides is abolished by IAP^{2,3}. Finally, the guanine nucleotide-sensitive agonist binding component is larger than the nucleotide-insensitive antagonist binding component^{16,17}.

In the present study we purified muscarinic receptors from the digitonin extract of porcine brain by chromatography with an affinity gel of a specific ligand, 3-(2'-aminobenzhydryloxy)tropane¹⁸. The purified protein bound 3 nmol mg^{-1} of ³H-N-methylscopolamine (³H-NMS), representing a 3,000-fold purification. The protein was iodinated and submitted to SDS-polyacrylamide gel electrophoresis (SDS-PAGE). We found a major band with an apparent relative molecular mass (M_r) of 70,000, together with several minor bands (Fig. 1). The major band was the only band detected on rechromatography¹⁹, and proved to be the muscarinic receptor itself or its ligand-binding subunit, as it was also labelled with ³H-propylbenzylcholine mustard, an irreversible muscarinic ligand. The receptor protein purified in this way did not display GTP binding or hydrolysing activity, nor did it serve as a substrate of IAP-catalysed ADP-ribosylation.

GTP-binding proteins serving as substrates of IAP-catalysed ADP-ribosylation were purified from cholate extract of rat brain by sequential application of column chromatographic techniques using DEAE-Sephacel, Ultrogel AcA-34 and hydroxylapatite^{20,21}. The proteins freed of stimulatory guanine nucleotide regulatory protein (N_s) after passage through the final column were a mixture of two IAP substrates, as reported for bovine brain proteins^{22,23}; these were further separated on a column of DEAE-Toyopearl 650(S)²⁰. One of these heterotrimers consists of an α -, a β - and a γ - (M_r 41,000, 35,000 and ~10,000, respectively) and was used as purified N_i for the reconstitution experiments described below. No ligand for muscarinic receptors bound specifically to this protein.

Fig. 1 SDS-PAGE of iodinated receptor preparations used for reconstitution studies. Receptor preparations obtained in three independent preparations are in lanes 2-4. Lane 1, relative molecular mass marker proteins (bovine serum albumin, 67,000; ovalbumin, 45,000; and carbonic anhydrase, 30,000).

Methods. About 900 ml of a digitonin(1%)/cholate(0.1%) extract of membrane preparations from porcine cerebrum were passed through the ABT-agarose column (3 × 43 cm, 300 ml). The ABT-agarose column was washed with 1.5 l 0.2 M NaCl/20 mM K-phosphate buffer (pH 7.0)/0.1% digitonin, then a small column of hydroxylapatite (1 ml, 0.8 × 2 cm) was connected to one end of the ABT-agarose column. Muscarinic receptors were eluted from the ABT-agarose column with buffer containing 0.1 mM atropine and allowed to bind to the hydroxylapatite. After washing the hydroxylapatite column with 0.15 M K-phosphate buffer/0.1% digitonin, muscarinic receptors were eluted with 0.5 M K-phosphate buffer/0.1% digitonin. The preparation contained 265 pmol of muscarinic receptors, with a specific activity of 3,060 pmol mg^{-1} of protein in a volume of 6 ml. The amounts of muscarinic receptors and proteins were assessed by binding of ³H-NMS and with fluorescamine³³, respectively. The purified preparation was radioiodinated by the chloramine T method³⁴ and electrophoresed by the method of Laemmli³⁵, followed by autoradiography.

The muscarinic receptor and N_i proteins thus purified were reconstituted into phospholipid vesicles essentially by the method used for β -adrenergic receptors and N_s ²⁴. A mixture of these proteins with the crude brain phospholipid fraction and phosphatidylcholine in detergents, was submitted to gel filtration to obtain detergent-free phospholipid vesicles in the void-volume fraction. About 80% of the ³H-NMS-binding activity of the receptor protein and 50% of the GTPase activity of N_i was recovered in the vesicles. The fraction of the protein-bound ³H-NMS trapped by a membrane filter (Toyo Roshi TM2) increased from 12 to 43% on reconstitution, reflecting incorporation of the protein into the reconstituted vesicles.

N_i displayed Mg^{2+} -dependent GTPase activity both in phospholipid vesicles (Fig. 2) and in 0.1% Lubrol solution²⁰. Carbachol had no effect unless the receptor protein was also reconstituted into the N_i -containing vesicles; it increased the GTPase activity of N_i at all the concentrations of Mg^{2+} studied (0.15–15 mM). The degree of increase caused by the agonist was larger at lower concentrations of Mg^{2+} ; the affinity of N_i for Mg^{2+} , an activator of the GTPase, was enhanced by stimulation of muscarinic receptors in the reconstituted vesicles (Fig. 2).

Carbachol increased GTPase activity in the receptor- N_i vesicles in a concentration-dependent manner (Fig. 3): the half-maximal effective concentration (EC_{50}) was 3.6 μ M in the presence of 2.8 mM $MgCl_2$. This value was virtually the same as the

† To whom correspondence should be addressed.

Fig. 2 Magnesium-dependent GTPase activity in receptor- N_i vesicles with or without carbachol. Concentration of free Mg^{2+} is shown on the abscissa. The incubation medium was either further supplemented with 0.1 mM carbachol (●) or contained no carbachol (○).

Methods. N_i (90 μ g or 1 nmol) in 0.7 ml (pH 8.0) of buffer containing 35 mM HEPES, 0.55 mM EDTA, 1 mM dithiothreitol (DTT), 50 mM NaCl, 125 mM K-phosphate buffer, 0.75 mM $MgCl_2$ and 0.05% sodium cholate, was mixed with muscarinic receptor (1.2 μ g or 16 pmol) in 0.7 ml 0.5 M K-phosphate buffer, 0.07% digitonin, 0.7 ml of 0.5 mg ml^{-1} dimyristoyl phosphatidylcholine, 1 mg ml^{-1} brain extract (Folchi Fraction I, Sigma), 3.6 mg ml^{-1} sodium deoxycholate and 0.4 mg ml^{-1} sodium cholate, and reconstituted by gel filtration through a Sephadex column (1.2 $\times$ 25 cm) according to Brandt *et al.*²⁶. The column was prewashed and eluted with 20 mM HEPES, 1 mM EDTA, 1 mM DTT, 0.1 M NaCl and 1.5 mM $MgCl_2$. Vesicles (20 μ l per tube) prepared by this method were incubated at 30 °C for 30 min with 0.5 μ M [γ -³²P]GTP, 15 mM HEPES, 0.75 mM EDTA, 0.75 mM DTT and 75 mM NaCl/ $MgCl_2$ in a total volume of 0.1 ml per tube.

EC_{50} (3.8 μ M) for the carbachol-induced increase in GTPase activity of rat striatal membranes²⁵. The effect of carbachol was antagonized in a concentration-dependent manner by the simultaneous addition of atropine (Fig. 3). The dissociation constant for the atropine/receptor complex was calculated to be 7 nM from the data in Fig. 3 by assuming that atropine competed with carbachol for the same sites on the receptor molecules responsible for increasing the GTPase activity of coupled N_i . This value was virtually the same as the apparent dissociation constant (7.8 nM) for atropine-induced displacement of ³H-NMS from the receptor proteins in a detergent solution¹⁹.

We also determined the potency of carbachol in displacing ³H-NMS bound to the reconstituted vesicles. The apparent dissociation constant (180 μ M) obtained was much larger than the EC_{50} (3.6 μ M) for the GTPase activity. Presumably, agonists bind with a high affinity to a small fraction of receptor proteins that are coupled to N_i , and bind with a low affinity to the residual bulk of uncoupled receptors. It is reasonable to assume that the affinity of muscarinic receptors for agonists is enhanced by their coupling to GTP-binding proteins such as N_i ¹²⁻¹⁵.

N_i purified from rat brain was ADP-ribosylated when incubated with the A-protomer^{5,6} of IAP, the active component of this A-B toxin⁴, in the presence of NAD²⁰. The ADP-ribosylated N_i exhibited the same Mg^{2+} -dependent GTPase activity as did the native (non-ADP-ribosylated) N_i in Lubrol solution or reconstituted phospholipid vesicles. There was no increase in GTPase activity, however, when carbachol was added to the vesicles into which the ADP-ribosylated N_i , instead of the native N_i , was reconstituted together with muscarinic receptors (data not shown). The direct ADP-ribosylation of N_i in the reconstituted vesicles was then achieved in the same experimental conditions as in Figs 2 and 3 by further adding 0.6 mM NAD alone (control) or NAD plus 0.2 μ g of the A-protomer of IAP (ADP-ribosylated) to the GTPase assay mixture. The assay time was extended to 60 min to allow ADP-ribosylation to proceed in the vesicles. The addition of 0.1, 1, 10, 100 and

Fig. 3 Concentration-dependent increase of GTPase activity by carbachol in the absence of atropine (○) and antagonism by atropine with 33 μ M carbachol (●). Vesicles containing N_i and muscarinic receptor were prepared and incubated in a medium supplemented with 2.8 mM $MgCl_2$ as described in Fig. 2 legend.

1,000 μ M carbachol produced increases of 0, 10, 48, 86 and 112%, respectively in GTPase activity of the control vesicles (supplemented with NAD alone) and increases of 0, 0, 12, 27 and 41%, respectively, in ADP-ribosylated vesicles (NAD plus the A-protomer of IAP). The A-protomer had no effect in the absence of NAD. Thus, ADP-ribosylation by IAP interfered with the ability of N_i to couple to muscarinic receptors in the reconstituted vesicles.

In conclusion, muscarinic receptors purified from porcine brain are coupled to N_i , the IAP substrate, in phospholipid vesicles in such a manner that stimulation of the receptors by agonists gives rise to increases of the GTPase activity, or of the affinity for Mg^{2+} , of this GTP-binding protein. Subdivision of muscarinic receptors has been proposed based on tissue and agonist specificities²⁶. Two subtypes of muscarinic receptors in embryonic chick heart cells have been reported, one linked to adenylate cyclase inhibition and the other to phosphoinositide breakdown²⁷. In addition, a third type of muscarinic receptors in human astrocytoma has been reported^{28,29} which is coupled to phosphoinositide metabolism, rather than adenylate cyclase, via a GTP-binding protein that did not serve as the substrate of IAP-catalysed ADP-ribosylation, although receptor-linked activation of phospholipid metabolism and Ca^{2+} mobilization was mediated by an IAP substrate in guinea pig neutrophils³⁰ and rat mast cells^{31,32}. It remains to be shown whether the rat brain N_i coupled to muscarinic receptors is responsible for inhibition of adenylate cyclase or activation of phospholipase C under physiological conditions. Direct evidence for the receptor subtypes that interact with different effectors, and molecular characterization of these interactions should be obtained by further studies using reconstitution of purified proteins.

We thank Dr Tomiko Asano for her helpful advice. * To whom correspondence should be addressed

Sodium- and potassium-dependent ATPase [($\text{Na}^+ + \text{K}^+$)ATPase], which is responsible for the active transport of Na^+ and K^+ , is distributed universally among animal cell membranes and consists of two types of subunits, α and β (refs 1-4). The larger α -subunit with a relative molecular mass (M_r) of 84,000-120,000 is thought to have the catalytic role. We have now cloned and sequenced DNA complementary to the *Torpedo californica* electroplax messenger RNA encoding the α -subunit of ($\text{Na}^+ + \text{K}^+$)ATPase and have deduced the complete amino-acid sequence of the polypeptide. Some structural features of the α -subunit molecule related to the function of this active-transport protein are discussed.

Tryptic peptides from the purified *T. californica* ($\text{Na}^+ + \text{K}^+$)ATPase were isolated, analysed for amino-acid sequence and five peptide sequences determined (Fig. 1). A library of complementary DNA clones derived from poly(A)⁺ RNA from an electric organ of *T. californica* was then screened by hybridization with a mixture of synthetic oligodeoxyribonucleotides, which represented all possible cDNA sequences corresponding to part of the amino-acid sequence determined for one of the tryptic peptides (Fig. 1e). An upstream fragment of the cDNA insert of a clone thus isolated was used as probe to screen the cDNA library again, and a third screening was carried out with an upstream fragment of the cDNA insert of a clone that resulted from the second screening. Details of the cloning are given in the Fig. 2 legend.

Figure 2 shows the 3,365-nucleotide sequence (excluding the poly(dA) tract) of the cDNA encoding the α -subunit of *T. californica* ($\text{Na}^+ + \text{K}^+$)ATPase. Because the mRNA encoding this polypeptide has a size of ~4,000 nucleotides as estimated by blot hybridization analysis (data not shown), a 5'-terminal sequence of ~500 nucleotides is apparently missing from the sequence shown in Fig. 2. All of the five partial amino-acid sequences determined by peptide analysis (Fig. 1) were found to be encoded by the cDNA sequence in the same reading frame (amino-acid residues 228-240, 431-438, 535-550, 671-690 and 1,011-1,022). By using this reading frame, the amino-acid sequence of the cryptic portion of the ($\text{Na}^+ + \text{K}^+$)ATPase α -subunit was deduced (Fig. 2). The translational initiation site was assigned to the methionine codon at nucleotide residues 1-3 because this is the first in-frame ATG triplet that appears downstream of the nonsense codon TAA (nucleotide residues -39 to -37). Codon 1,022 specifying tyrosine is followed by a translational termination codon (TAG). Thus, we conclude that the α -subunit of *T. californica* ($\text{Na}^+ + \text{K}^+$)ATPase is composed of 1,022 amino-acid residues (including the initiating methionine) and has a calculated M_r of 112,424. This polypeptide does

Fig. 1 Sequence analysis of peptides from the α -subunit of *T. californica* ($\text{Na}^+ + \text{K}^+$)ATPase. Fractions Ia (a), IIa (b), IIIa (c), IVa (d) and Va (e) were subjected to amino-acid sequence analysis with a gas-phase sequencer²⁶ (model 470 A, Applied Biosystems).

Methods. The microsomal fraction (673 mg of protein) derived from ~200 g of *T. californica* electric organ (Pacific Bio-Marine Laboratories) was treated with SDS²⁷ in the presence of 3 mM ATP and 30% (w/v) glycerol and centrifuged in the discontinuous gradient of 30% (w/v) and 42% (w/v) sucrose. The material at the interface was collected and treated with 3 mg ml⁻¹ octaethylene glycol mono-*n*-dodecyl ether⁹ at a protein concentration of 1.5 mg ml⁻¹ and then centrifuged. The resulting supernatant contained 81 mg of purified ($\text{Na}^+ + \text{K}^+$)ATPase. The enzyme was treated with 1% SDS and fractionated by gel filtration on a Biogel A-1.5m column²⁸ (2.5 × 100 cm). The fraction consisting mainly of the α -subunit was subjected to chromatography on a concanavalin A-Sepharose column²⁹ (1.2 × 11 cm) followed by gel filtration on the same Biogel A-1.5m column to yield 1.2 mg of purified α -subunit. This was dialysed for two days against 10 mM sodium phosphate buffer, pH 7.2, containing 6 M urea, in which particles of Dowex AG1-X2 resin were suspended for efficient removal of SDS, and was then dialysed for 20 h against 0.1 M ammonium bicarbonate, pH 8.0 or 0.2 M ammonium acetate, pH 8.0. The dialysed material was concentrated and treated with TPCK-treated trypsin (Worthington) at room temperature for 16 h in the absence or presence of 10 mM CaCl₂; the α -subunit/trypsin ratio was 50. A further identical aliquot of TPCK-treated trypsin was added, and the incubation was continued for additional 8 h. The tryptic digest was directly loaded onto a Hi-Pore C₄ column (4.6 × 250 mm; Bio-Rad) equilibrated with 0.1% trifluoroacetic acid, and a linear gradient of 0-50% (over 50 min) or 0-30% (over 60 min) acetonitrile was applied at a flow rate of 1 ml min⁻¹. Five fractions were collected and rechromatographed on the same column to yield fractions Ia-Va. Phenylthiohydantoin (PTH)-amino acids were analysed by HPLC at 40 °C using a Senshu-Pak column (4.6 × 300 mm) with a three-solvent gradient (acetonitrile, water and 40 mM sodium acetate buffer, pH 4.7) at a flow rate of 1 ml min⁻¹. The yield of PTH-amino acids at each cycle of Edman degradation is shown; the one-letter amino acid notation is used.

Methods. The Okayama-Berg cDNA library³² used was the same as that screened for cDNAs encoding the acetylcholine receptor subunits³³. The transformation and screening procedures were as described previously³⁴. The oligodeoxyribonucleotide probe used for isolating pNKA α 1 was a mixture of 32 hexadecamers, 5'-GT₂TC₂TG₂TCNACC-3' (synthesized³⁵ as two pools containing A/T or G/C at position 12, where N denotes a mixture of A, T, G and C), which corresponds to the sequence Trp-Val-Glu-Gln-Glu-Thr at positions 1,015-1,020; the probe was ³²P-labelled at the 5' end. Screening of $\sim 2.5 \times 10^4$ transformants yielded 56 clones that hybridized with the probe at 46°C. Four randomly selected clones were isolated; pNKA α 1 carried apparently the largest cDNA insert among them. To clone a further upstream sequence, we screened the same cDNA library by hybridization at 60°C with the *Bst*NI(2,579)/*Taq*I(2,739) fragment excised from pNKA α 1 and labelled by nick-translation³⁶ with [α -³²P]dCTP; the restriction endonuclease sites are identified by numbers indicating the 5'-terminal nucleotide generated by cleavage. From $\sim 5 \times 10^4$ transformants, 136 hybridization-positive clones were thus obtained. Among the 31 clones selected randomly, pNKA α 8 harboured apparently the largest cDNA insert. The filters screened for isolating pNKA α 8 were re-used for hybridization at 68°C with the nick-translated ~ 250 -base-pair fragment (excised from pNKA α 8) extending from the *Pst*I site flanking the cDNA insert to the *Pst*I(604) site. Among the seven hybridization-positive clones isolated (including pNKA α 8), pNKA α 87 carried apparently the largest cDNA insert.

Fig. 3 Hydropathy profile and predicted secondary structures of the $(\text{Na}^+ + \text{K}^+)\text{ATPase } \alpha$ -subunit. The averaged hydropathic index of a nonadecapeptide composed of amino-acid residues $i-9$ to $i+9$ is plotted against i , where i represents amino acid number; the hydropathy indices of individual amino acids are taken from ref. 12. The positions of the predicted structures of α -helix and/or β -sheet¹³ that have a length of ≥ 10 residues are shown by open boxes, and those of the putative transmembrane segments M1-M6 by closed boxes. The phosphorylation and FITC-reactive sites are indicated.

not possess a hydrophobic amino-terminal sequence characteristic of the signal peptide⁵.

The sequence of amino-acid residues 2-17 (with a gap of residues 4-7) is homologous with the amino-terminal sequence of the mammalian^{6,7} and avian $(\text{Na}^+ + \text{K}^+)\text{ATPase } \alpha$ -subunit⁸, and the sequence of residues 2-47 (with gaps of residues 5-19, 22 and 27-30) with that of the *Artemia salina* counterpart⁹. Furthermore, some of the partial sequences of the lamb kidney $(\text{Na}^+ + \text{K}^+)\text{ATPase } \alpha$ -subunit, determined by analysis of tryptic peptides¹⁰, have homologous counterparts in the *Torpedo* sequence (for example, residues 502-512, 596-606 and 647-657). Five potential *N*-glycosylation sites¹¹ (residues 215, 405, 483, 637 and 719) are found in the *Torpedo* α -subunit sequence, but all of them are assigned to the cytoplasmic side of the membrane (see below).

Analysis of the amino-acid sequence of the $(\text{Na}^+ + \text{K}^+)\text{ATPase } \alpha$ -subunit for local hydropathy¹² and predicted secondary structure¹³ (Fig. 3) suggests the presence of at least six transmembrane segments forming presumably α -helical structures, that is, M1 (residues 95-122), M2 (129-150), M3 (294-318), M4 (320-348), M5 (786-809) and M6 (848-873). These hydrophobic segments comprise a continuous stretch of 22-29 uncharged residues including many nonpolar residues, except that segment M4 contains a glutamic acid residue (residue 334) in the middle, which is flanked by proline and glycine. If segment M5 or M6 is assumed to extend over a wider range (residues 774-823 and 848-885, respectively), the possibility

remains that one or both of these segments span the membrane twice in a hairpin shape. If this was the case, segments M5 and M6 would also contain three and two acidic residues, respectively, as sole charged residues.

It is possible that the transmembrane segments take part in the cation-conducting pathway and that the acidic residues within these segments are involved in the transport of cations. Of interest in this context is that $(\text{Na}^+ + \text{K}^+)\text{ATPase}$, in its normal catalytic cycle, passes through states in which cations are occluded within the enzyme molecule so that they are not exchangeable^{14,15}. Three additional hydrophobic segments comprising exclusively uncharged residues (residues 919-931, 961-973 and 984-1,000) are present near the carboxy-terminus (Fig. 3). They seem to be too short to span the membrane, but the possibility remains that some of them traverse the membrane if a longer stretch is assumed. They may be associated with the membrane or may be involved in hydrophobic inter- or intra-subunit interaction.

The sequence surrounding the aspartic acid residue that is phosphorylated by ATP¹⁶ (Cys-Ser-Asp-Lys) is located at residues 374-377. The site reactive with fluorescein 5'-isothiocyanate (FITC)^{17,18} (His-Leu-Leu-Val-Met-Lys-Gly-Ala-Pro-Glu-Arg), which is thought to be at or near the ATP binding site, is positioned at residues 502-512, except that the amino-terminal histidine residue is replaced by tyrosine. Because these functional regions reside on the cytoplasmic side of the membrane, the transmembrane topology of the $(\text{Na}^+ + \text{K}^+)\text{ATPase}$

Fig. 4 Alignment of the amino-acid sequences of the *T. californica* $(\text{Na}^+ + \text{K}^+)\text{ATPase } \alpha$ -subunit (top), rabbit skeletal sarcolemmal reticulum Ca^{2+} -ATPase (middle) and the KdpB protein of *E. coli* Kdp-ATPase (bottom). The sequences of the Ca^{2+} -ATPase and the KdpB protein have been taken from refs 24 and 25, respectively. The one-letter amino-acid notation is used. Sets of identical residues are enclosed with solid lines and sets of conservative residues by dotted lines; conservative substitutions are defined

as pairs of residues belonging to one of the following groups: S, T, P, A and G; N, D, E, Q and Z; H, R and K; M, I, L and V; F, Y and W (ref. 37). Gaps (-) have been inserted to achieve maximum homology. The non-homologous segments are shown by lines together with the sum of residues present in each segment given in parentheses. The residues of the $(\text{Na}^+ + \text{K}^+)\text{ATPase } \alpha$ -subunit and the KdpB protein are numbered beginning with the initiating methionine of the respective polypeptides. The residues of the Ca^{2+} -ATPase, whose numbers (see ref. 24) are not shown, are as follows (from the amino- to the carboxy-terminus): sequence 1 (S1), 10-30; S2, 3-115; S3, 1-42; S3, 185-201; S3, 264-298; S4, 1-18; S4, 38-120. The aspartic acid residue that is phosphorylated and the lysine residue reactive with FITC are marked with asterisks. For evaluating homology (see text), only the segments comprising residues 180-227, 351-382, 504-518, 592-614, 630-632 and 690-767 of $(\text{Na}^+ + \text{K}^+)\text{ATPase}$ have been taken into account; gaps have been counted as one substitution regardless of their length, and the position including Z has been excluded from the calculation for all pairs.

α -subunit molecule is assigned such that the amino-terminal region, the regions between segments M2 and M3 and between segments M4 and M5 and the carboxy-terminal region are located on the cytoplasmic side (assuming the presence of six transmembrane segments). Thus, the regions between segments M1 and M2, between segments M3 and M4 and between segments M5 and M6 are assigned to the extracellular side of the membrane, where the ouabain binding site is situated. The transmembrane topology assigned is generally consistent with the model proposed on the basis of specific covalent labelling combined with proteolysis¹⁹⁻²¹. Furthermore, our assignment generally supports the asymmetric partition of the α -subunit molecule across the membrane, favouring the cytoplasmic region^{22,23}.

Figure 4 shows the alignment of the homologous amino-acid sequences of the *T. californica* ($\text{Na}^+ + \text{K}^+$)ATPase α -subunit, rabbit skeletal sarcoplasmic reticulum Ca^{2+} -ATPase²⁴ and the KdpB protein of *Escherichia coli* Kdp-ATPase²⁵ (more than half of the sequence of the Ca^{2+} -ATPase has been determined by protein analysis²⁴). The degree of homology for the total segments where sequences of all the three polypeptides can be aligned is 58, 37 and 36% for the pairs ($\text{Na}^+ + \text{K}^+$)-ATPase/ Ca^{2+} -ATPase, ($\text{Na}^+ + \text{K}^+$)ATPase/Kdp-ATPase and Ca^{2+} -ATPase/Kdp-ATPase, respectively. This suggests that the three polypeptides evolved from a common ancestor. The regions conserved in all the three polypeptides, including the phosphorylation and FITC binding sites, may be involved in the basic energy transduction process common to these ion transport ATPases rather than in their ion selectivity, which is different for each enzyme.

We thank Drs Paul Berg and Hiroto Okayama for providing their high-efficiency cloning system and Japan Scientific Instrument Co. for determining amino-acid sequences. This investigation was supported in part by research grants from the Ministry of Education, Science and Culture of Japan, the Mitsubishi Foundation and the Japanese Foundation of Metabolism and Diseases.

Voltage-dependent ATP-sensitive potassium channels of skeletal muscle membrane

A. E. Spruce, N. B. Standen & P. R. Stanfield

Department of Physiology, University of Leicester, University Road, Leicester LE1 7RH, UK

It has been known for some years that skeletal muscle develops a high potassium permeability in conditions that produce rigor, where ATP concentrations are low and intracellular Ca^{2+} is high¹. It has seemed natural to attribute this high permeability to K channels that are opened by internal Ca^{2+} , especially as the presence of such channels has been demonstrated in myotubes and in the transverse tubular membrane system of adult skeletal muscle²⁻⁴. However, as we show here, the surface membrane of frog muscle contains potassium channels that open at low internal concentrations of ATP (<2 mM). ATP induces closing of these channels without being split, apparently holding the channels in one of a number of closed states. The channels have at least two open states whose dwell times are voltage-dependent. Surprisingly, we find that these may be the most common K channels of the surface membrane of skeletal muscle.

To record unitary currents through the potassium channels, we have used the patch-clamp technique⁵ on large sarcolemmal vesicles prepared by KCl loading and enzymatic treatment^{6,7}. We used recording pipettes filled with a 60 mM KCl solution in most cases, and held the membrane potential of the patch at a negative level. In these conditions, channel activity appeared only when the patch was excised from the vesicle, so that its inner surface came into contact with a 120 mM KCl solution, free of ATP. Figure 1 illustrates one such experiment, in which the patch was held at a membrane potential of -60 mV and was exposed in turn to solutions containing ATP at 0.5 and 2 mM, interspersed with exposures to ATP-free solution. The presence of ATP reduces the probability of the channels being open, P_{open} , from 0.496 ± 0.152 ($n = 16$) in ATP-free solution at -60 mV (60 mM external $[\text{K}]_0$) to 0.154 ± 0.033 ($n = 4$) in 0.5 mM ATP.

ATP closes channels without being metabolized. First, most of the patches were exposed to internal solutions free of Mg^{2+} (three of the four patches exposed to 0.5 mM ATP). Second, the non-metabolizable analogue of ATP, adenylylimidodiphosphate (AMP-PNP, 0.5 mM) was equally effective at closing channels, reducing P_{open} to 0.129 and 0.226 in two patches. (In one further patch, 0.5 mM ATP and 0.5 mM AMP-PNP both silenced all four channels that the patch contained.) However, ADP was much less effective than ATP.

The ATP-sensitive channel is selective for K^+ , as its current-voltage relation (Fig. 2c) reverses at the equilibrium potential for potassium ions (E_K). With 60 mM K^+ in the pipette, this reversal potential was -18.2 ± 0.7 mV ($n = 5$), close to the theoretical value of -17.3 mV. Reducing the pipette K^+ concentration altered the reversal potential appropriately, to -27 mV in 40 mM $[\text{K}]_0$ (one patch) and to -54 and -60 mV (two patches) in 10 mM $[\text{K}]_0$. Channel conductance was also dependent on external K^+ concentration, being reduced from 48.2 ± 1.5 pS ($n = 5$) in 60 mM K^+ to 17.8 and 18.0 pS in 10 mM K^+ . The channel is highly selective: Rb^+ does not permeate when it is substituted for K^+ in the pipette (not shown), even though it permeates several other classes of K channel.

As well as being decreased by the presence of ATP, channel opening is also affected by membrane potential, although it is not increased by Ca^{2+} , unlike the opening of Ca-activated K channels, which also have a higher unitary conductance³. We have demonstrated the voltage dependence in two ways: by holding the potential close to E_K and then stepping the potential for periods of 50 ms (Fig. 2a, b), and by recording for prolonged periods (average ~90s) at different holding potentials and subsequently measuring open and closed times (Fig. 3). The experi-

Fig. 1 Effect of ATP on K^+ -channel currents in an inside-out patch of membrane excised from a sarcolemmal vesicle formed from frog muscle⁷. The patch pipette contained 60 mM KCl, 60 mM NaCl, 1.8 mM $CaCl_2$ and 5 mM Tris-maleate, pH 7.2. The membrane potential was -60 mV throughout. The cytoplasmic face of the membrane was exposed to different ATP concentrations by moving the pipette tip between the mouths of a series of pipes down which test solutions flowed at $1-2$ ml h^{-1} (ref. 16). These solutions contained 5 mM EGTA neutralized with KOH, KCl to bring $[K^+]$ to 120 mM, 2 mM $MgCl_2$, ATP at the concentration indicated, and 10 mM HEPES buffer, pH adjusted to 7.2 with KOH. The patch was exposed to the solutions in the order *a*, *b*, *c*, *d*, *e* and we have shown the total time of recording in each case. Currents were recorded with a List electronic EPC-5 patch-clamp amplifier onto FM tape (Racal Store 4, 30 i.p.s.) and were filtered at 0.5 kHz (3 dB down, 8-pole Bessel) before display. The current levels corresponding to 0, 1, 2, 3 and 4 open channels are indicated at the right of record *a*. P_{open} was calculated as $(\sum_{j=1}^N t_j)/TN$ where t_j is the time spent at each level, j corresponding to 1, 2, ..., N channels open (where N is the maximum number of channels seen in ATP-free solution), and T is the duration of the recording. Analysis was done using a computer after the current record had been digitized (see Fig. 2 legend). In this experiment the P_{open} values were: *a*, 0.401; *b*, 0.175; *c*, 0.251; *d*, 0.004; *e*, 0.222. Mean values in ATP-free solution and in 0.5 mM ATP are given in the text. A second patch exposed to 2 mM ATP had $P_{open} = 0.012$. In two patches exposed to 0.1 mM ATP, P_{open} was 0.255 and 0.225; in the same patches in 0.02 mM ATP, P_{open} was 0.398 and 0.344.

ments involving stepping of the membrane potential show that the mean current per trace declines with time under hyperpolarization (Fig. 2*a*), indicating that hyperpolarization partly inactivates the potassium conductance. However, depolarization from -17 mV does not further activate conductance (Fig. 2*b*). We used this stepping procedure routinely to measure current-voltage relations for the channel (as in Fig. 2*c*).

The records of Figs 1 and 2*a* indicate that the channel opens and shuts rapidly. Channel openings occur in bursts separated by intervals that may be quite brief (Fig. 2*a*) or very long (Fig. 1*b*, *e*), showing that the channel has complex kinetics. Open-time histograms (Fig. 3*a-c*) are better fitted by two exponentials, suggesting two open states⁸. The presence of two components in the open time distribution is clearer at -40 mV (Fig. 3*c*) than at -60 mV (Fig. 3*a*), partly because of an increase in time

Fig. 2 *a*, Single-channel currents recorded from ATP-sensitive channels when a membrane patch was stepped for 50 ms from the holding potential of -17 mV (close to the calculated E_K) to -97 mV. The top trace shows the voltage step, the middle trace a sample current record, and the bottom trace the average of 64 such current records. The current was filtered at 2 kHz and digitized at 10 kHz (Cambridge Electronic Design 502) before analysis with a DEC PDP 11/23 computer. Capacitive and leakage currents caused by the voltage step have been removed from the current trace by analog compensation and digital subtraction⁷. For display, the number of data points in the current records was increased fourfold by interpolation using a cubic spline method¹⁷. We used this voltage-step protocol as it has been commonly used to study the 'inward rectifier' K channels of muscle¹⁸. The ATP-sensitive channels described here are not inward rectifier channels, however, as they are not open at the resting potential on intact muscle fibres and they show only a slight rectification, (*c*), rather than the extreme rectification associated with the inward rectifier. Also, their single-channel conductance is much larger than that measured for inward rectifier channels by noise analysis¹⁹. *b*, Currents recorded as in *a* but for a step in potential to $+63$ mV. Top trace, voltage; middle trace, current; bottom trace, average of 24 current records. *c*, Mean single-channel current-voltage ($I-V$) relation for the ATP-sensitive channel. Single-channel currents were recorded using 50-ms steps in membrane potential as in *a* and *b*; current amplitude was measured by fitting gaussian distributions to histograms of digitized current values⁹. The points show the mean values for four or five patches and the bars show the s.e.m. where this is larger than the symbols. The recording pipette contained 60 mM K^+ , while the solution bathing the cytoplasmic face of the patch contained 120 mM K^+ . The decrease in conductance at positive potentials was associated with an increase in the open-channel current noise, as can be seen in the middle record of *b*.

constant of the slower component with depolarization. There appear to be relatively more brief openings in the presence of ATP (Figs 1*d*, 3*b*).

Closed-time distributions (Fig. 3*d-f*) indicate the presence of at least three closed states. However, we have not recorded for sufficiently long periods to measure the length of more than a few of the very long periods of closing, which are therefore not well represented in the closed-time histograms of Fig. 3. In fact, ATP apparently increases the chance of the channel entering a closed state with a very long dwell time. ATP reduced the several levels of opening seen in multichannel patches to one or two levels of opening (see Fig. 1), indicating that several of the channels are silent throughout the 90-s recording period. The shorter closed times in Fig. 3*b* are little affected by ATP.

Fig. 3 Histograms of open (*a-c*) and closed (*d-f*) times for the ATP-sensitive channel, constructed from periods of recording lasting between 39 and 51 s, during which only a single level of opening was seen. The pipette contained 60 mM K⁺. *a-c*, Effects of ATP (*a, b*) and membrane potential (*a, c*) on open-time distribution. These distributions have been fitted using a least-squares algorithm to the double-exponential probability density function (p.d.f.):

$$f(t) = A \exp(-t/\tau_1) + B \exp(-t/\tau_2).$$

ATP increases the value of *A*, reduces τ_1 , but has little effect on τ_2 . Depolarization increases τ_2 . *a*, Open-time histogram in ATP-free solution; holding potential -60 mV. The fitted p.d.f. has $A = 0.029 \text{ ms}^{-1}$, $B = 0.168 \text{ ms}^{-1}$, $\tau_1 = 1.85 \text{ ms}$ and $\tau_2 = 5.65 \text{ ms}$. *b*, Open-time histogram at -60 mV in 0.5 mM ATP solution for the same patch as *a*. The fitted p.d.f. has $A = 0.109 \text{ ms}^{-1}$, $B = 0.172 \text{ ms}^{-1}$, $\tau_1 = 0.34 \text{ ms}$, $\tau_2 = 5.58 \text{ ms}$. *c*, Open-time histogram at -40 mV in ATP-free solution. The fitted p.d.f. has $A = 0.118 \text{ ms}^{-1}$, $B = 0.081 \text{ ms}^{-1}$, $\tau_1 = 0.59 \text{ ms}$, $\tau_2 = 11.56 \text{ ms}$. *d-f*, Effects of ATP (*d, e*) and membrane potential (*d, f*) on closed-time distribution. These distributions have been fitted with three exponentials. The two slowest were fitted to a histogram formed with 2-ms bins and the fastest was fitted after the histogram had been re-formed using 0.2-ms bins (insets). The fitted p.d.f. is given by

$$f(t) = A \exp(-t/\tau_1) + B \exp(-t/\tau_2) + C \exp(-t/\tau_3)$$

ATP has little effect on the distribution measured, but appears to place channels in a closed state too long-lived to contribute significantly to the histograms shown. *d*, Closed-time histograms in the same conditions and for the same patch as in *a*. The fitted p.d.f. has $A = 2.231 \text{ ms}^{-1}$, $B = 0.012 \text{ ms}^{-1}$, $C = 0.002 \text{ ms}^{-1}$, $\tau_1 = 0.41 \text{ ms}$, $\tau_2 = 4.56 \text{ ms}$, $\tau_3 = 14.23 \text{ ms}$. *e*, Closed-time histograms in the same conditions as in *b*. The fitted p.d.f. has $A = 2.331 \text{ ms}^{-1}$, $B = 0.011 \text{ ms}^{-1}$, $C = 0.004 \text{ ms}^{-1}$, $\tau_1 = 0.40 \text{ ms}$, $\tau_2 = 2.64 \text{ ms}$, $\tau_3 = 11.07 \text{ ms}$. *f*, Closed-time histograms in the same conditions and for the same patch as in *c*. The fitted p.d.f. has $A = 2.997 \text{ ms}^{-1}$, $B = 0.066 \text{ ms}^{-1}$, $C = 0.008 \text{ ms}^{-1}$, $\tau_1 = 0.26 \text{ ms}$, $\tau_2 = 1.8 \text{ ms}$, $\tau_3 = 12.41 \text{ ms}$.

The ATP-sensitive channels are very common in skeletal muscle. The patches that we have analysed in detail contained an average of 3.6 ± 0.4 channels ($n = 16$). Several other patches were not analysed because of the very high number of channels (occasionally as many as 10 or more) that were active. As our patch electrodes had tips with openings of only 0.3–0.4 μm diameter (as measured with a scanning electron microscope), a high channel density is indicated—as high as or higher than that of ‘delayed rectifier’ K channels in the same preparation⁹.

However, while the role of delayed rectifier channels is well

known (to repolarize the action potential), that of ATP-sensitive channels is less clear, particularly since the ATP concentration in frog muscle is high (4.9 mM)^{10,11} and is well buffered by creatine phosphate and creatine kinase. We find that the channels are closed in patches formed on resting intact muscle, but anticipate that channels will open under rigor conditions, contributing to the high potassium permeability then found¹. Nevertheless, it seems likely that channels that are present at such high density will have an important physiological role. While we point out that the regulating effect of ATP occurs at concentrations much closer to the physiological range than has been reported previously for ATP-sensitive channels of heart muscle¹² and of B cells of pancreatic islets^{13,14}, it is possible that the sensitivity to ATP in intact membranes is different from that found in excised patches or that some other metabolic constituent of sarcoplasm contributes to their control.

In man, the severest exercise may reduce the concentration of ATP in muscle by 45% (ref. 15). As we have found that open times for the ATP-sensitive channel also increase with depolarization, the channel may play a part in the regulation of K conductance during muscle activity. Alternatively, as the channel is present in surface membrane of muscle (and in non-contractile cells^{13,14}), its role may be primarily to sense submembrane, rather than myofibrillar, levels of ATP or other metabolites.

We thank MRC and the Wellcome Trust for support. A.E.S. is a MRC scholar. We also thank Dr F. M. Ashcroft, Dr Tom Ward and Mr N. C. Sturgess for discussions, and Mr G. McTurk for scanning electron microscopy of the patch electrodes.

I–J as an idio type of the recognition component of antigen-specific suppressor T-cell factor

Takayuki Sumida*, Toshihiko Sado†, Masaharu Kojima*, Kumeo Ono*, Hitoko Kamisaku† & Masaru Taniguchi*

* Department of Immunology, School of Medicine, Chiba University, 1-8-1 Inohana, Chiba, 280 Japan

† Division of Physiology and Pathology, National Institute of Radiological Science, Anagawa, Chiba, Japan

The I–J determinant of membrane glycoprotein is known to be expressed exclusively on suppressor T cells (Ts), which have a crucial role in the regulation of immune responses¹. I–J also comprises part of the soluble factor (TsF) with suppressor activity which is secreted from Ts. Gene-mapping experiments have indicated that the I–J gene lies between the I–A and I–E subregions of the mouse major histocompatibility complex (MHC)^{2,3} and is defined by the H-2 congenic pair, that is, B10.A(3R) and B10.A(5R)⁴. In fact, antibodies raised in the reciprocal combina-

tions of B10.A(3R) and B10.A(5R) define the $I-J^b$ and $I-J^k$ alleles, and are able to detect the I-J determinants on Ts and TsF. Biochemical and functional analyses⁵⁻¹⁰, using I-J-positive Ts clones and hybridomas, have demonstrated that monoclonal anti-I-J antibodies precipitate $I-J^k$ or $I-J^b$ with a relative molecular mass of 25,000–28,000 (25–28K) and that the $I-J^+$ molecule mediates the restriction specificity of TsF in association with an antigen-binding protein (45K). However, molecular genetic studies on the $I-J$ gene¹¹⁻¹³ reveal no genetic difference between B10.A(3R) and B10.A(5R) and also that there is no room to accommodate a gene encoding I-J in the expected I region. These discrepancies between the molecular genetic and serological/functional data require explanation. Here we demonstrate that Ts and TsF expressing I-J of the host type were produced by fully allogeneic bone marrow cells of donor origin in chimaeric mice, when the chimaeras received the host antigen-presenting cells (APC) at the time of immunization. The results show that APC are necessary for the activation and clonal expansion of Ts and also support the notion that I-J is an idiotypic determinant of the recognition component of Ts and TsF.

To analyse the nature of I-J, chimaeric mice were prepared as described elsewhere¹⁴. C57BL/6($H-2^b$) or C3H($H-2^k$) mice were irradiated with 10.63 Gy and reconstituted with T-cell-depleted allogeneic bone marrow cells from C3H($H-2^k$), C57BL/6($H-2^b$), B10.A(3R)($H-2^{13}$) or B10.A(5R)($H-2^{15}$) mice. The chimaeras were kept for 4 months, then immunized with keyhole limpet haemocyanin (KLH). Primed thymocytes and spleen cells were tested for their H-2 phenotypes before preparation of TsF and were shown to possess the H-2 type of donor origin (Table 1). KLH-specific suppressor T-cell factor (KLH-TsF) was prepared by freezing and thawing of thymocytes from KLH-primed chimaeric mice, as described elsewhere³, and tested for its effects on the *in vitro* secondary anti-dinitrophenyl (DNP) IgG plaque-forming cell (PFC) responses of $H-2^k$ and $H-2^b$ mice. As shown in Table 2, KLH-TsF from the C3H $\rightarrow$ C57BL/6 chimaera, like C3H TsF, suppressed the C3H but not the C57BL/6 response in a KLH-specific manner, because only the C3H response to DNP-KLH, but not to DNP-ovalbumin (OVA), was suppressed. Similarly, the C57BL/6 $\rightarrow$ C3H TsF specifically suppressed the response of C57BL/6 but not that of C3H. Therefore, KLH-TsF from chimaeric mice expresses the restricting specificity of the donor type. These results indicate that the chimaeric mice produce TsF bearing I-J of the donor type, as the restriction specificity is mediated by the $I-J^+$ molecule^{7,8} and because of the fact that the I-J phenotype of TsF must be the same as that of the responding cells^{7,8,15}. A similar conclusion was reached for chimaeras using B10.A(3R) or B10.A(5R) as the donor (Table 2). B10.A(3R) $\rightarrow$ C3H and B10.A(3R) $\rightarrow$ C57BL/6 produced $H-2^b$ -restricted TsF whereas TsF from either B10.A(5R) $\rightarrow$ C3H or B10.A(5R) $\rightarrow$ C57BL/6 suppressed only the $H-2^k$ responses. Thus, KLH-TsF from chimaeras using B10.A(3R) or B10.A(5R) is the same as KLH-TsF from conventional B10.A(3R) or B10.A(5R) mice, which produce $I-J^b$ -TsF or $I-J^k$ -TsF, respectively⁷.

The results in Table 2 show that the host-specific restriction specificity of TsF is not acquired in the chimaera situation and indicate that the I-J phenotype cannot be changed, thus I-J seems to be an MHC-controlled product. It is, however, possible that only the donor-restricted but not host-specific Ts are allowed to expand after antigenic stimulation because there is no APC of the host type present and most APC are replaced by those of donor origin in the 4-month chimaera^{14,16}. To test this possibility, the chimaeric mice were given APC of the host type at the time of immunization with KLH. As shown in Table 2, KLH-TsF from either the C3H $\rightarrow$ C57BL/6 or C57BL/6 $\rightarrow$ C3H chimaera that received the host APC specifically suppressed the responses of both C57BL/6 and C3H but not those of a third party, such as BALB/c mice, despite the fact that these chimaeric thymocytes expressed H-2 of donor type alone. It is clear, therefore, that fully allogeneic chimaeras (subjected to irradiation of the bone marrow) can generate both donor and host H-2-restricted KLH-TsF. Whether the former or the latter type of TsF is

Table 1 H-2 typing of thymocytes from fully allogeneic chimaeras

Chimaeras	% Cytotoxicity with antibodies against			
	H-2D ^b	H-2D ^d	H-2K ^b	H-2K ^k
C3H $\rightarrow$ C57BL/6	<10%	—	—	>95%
C57BL/6 $\rightarrow$ C3H	>95%	—	—	<10%
C3H $\rightarrow$ C57BL/6 with C57BL/6 APC	<10%	—	—	>95%
C57BL/6 $\rightarrow$ C3H with C3H APC	>95%	—	—	<10%
B10.A(3R) $\rightarrow$ C57BL/6	<10%	>95%	—	—
B10.A(3R) $\rightarrow$ C3H	—	—	>95%	<10%
B10.A(5R) $\rightarrow$ C57BL/6	<10%	>95%	—	—
B10.A(5R) $\rightarrow$ C3H	—	—	>95%	<10%

Fully allogeneic chimaeric mice were prepared as described previously¹⁴. Briefly, C57BL/6($H-2^b$) or C3H($H-2^k$) mice were irradiated with 10.63 Gy of ¹³⁷Cs γ -rays, and reconstituted 24 h later with 10⁷ T cell-depleted allogeneic bone marrow cells from C3H($H-2^k$), C57BL/6($H-2^b$), B10.A(3R)($H-2^{13}$) or B10.A(5R)($H-2^{15}$) pretreated with monoclonal anti-Thy-1.2 antibody (F7D5; Olac Ltd, Bicester, UK) plus complement. The mice were maintained for 4 months in pathogen-free conditions and then used for experiments. The chimaeras (with or without addition of APC of the host type) were immunized with 200 μ g of keyhole limpet haemocyanin (KLH) after a 2-week interval as described elsewhere³. Primed spleen cells and thymocytes from the chimaeras were tested for their H-2 phenotypes in a dye exclusion cytotoxicity assay using anti-H-2D^d antiserum (B10A.(2R) anti-B10.A) and various monoclonal anti-H-2 antibodies, that is anti-H-2D^b (H141-30; BALB/c anti-C57BL/6), anti-H-2K^b (K9-178.9; (C3H $\times$ A)F₁ anti-70.Z/3) and anti-H-2K^k (H100-5.28, BALB/c anti-CBA) (given by Dr G. J. Hammerling) before preparation of TsF. For the cytotoxicity test, spleen cells or thymocytes (10⁵) from the chimaeras were resuspended in Dulbecco's modified minimal essential medium enriched with 2% fetal calf serum (FCS) and were incubated with 20 μ g of a 1:10 dilution of anti-H-2 antiserum and monoclonal anti-H-2 antibodies at a final concentration of 1:1,000 for 15 min at room temperature. The cells were washed twice, then reacted with 20 μ l of a 1:10 dilution of rabbit complement at 37 °C for 30 min. Dead and viable cells were counted under the light microscope by Trypan blue dye exclusion.

generated depends solely on the H-2 type of the APC available at the time of antigen stimulation. The above results also show that APC are necessary for the activation and clonal expansion of Ts. These findings support the data of Takaoki *et al.*¹⁷ and Lowy *et al.*¹⁸, who demonstrated that accessory cells are involved at various stages in suppressor cell interactions.

Two further experiments were done to obtain direct evidence that I-J of the host type is indeed generated from the donor cell type. The first experiment was designed to investigate the H-2 phenotype of the cells producing TsF having host or donor restriction specificity. Thymocytes from C57BL/6 $\rightarrow$ C3H chimaeras that received C3H APC were treated with antibodies against H-2 products of the host or donor type, together with complement, before preparing the chimaeric TsF. The TsF was then tested for its activity. The results are shown as Expt. 3 of Table 2. The chimaeric TsF suppressed both C57BL/6 and C3H responses. However, TsF obtained from the chimaeric thymocytes pretreated with antibody against H-2 of donor type failed to suppress the responses, whereas both B6 and C3H responses were suppressed by TsF from chimaeric thymocytes pretreated with anti-host antibody and complement. Therefore, both donor- and host-restricted TsF were produced by the cells bearing H-2 of the donor type.

In the second experiment, KLH-TsF derived from the chimaeric mice (either C3H $\rightarrow$ C57BL/6 or C57BL/6 $\rightarrow$ C3H) that received host APC was applied to a column of anti-I-J^b or anti-I-J^k. The effluent and the acid eluate were tested for their suppressor activity on the C57BL/6 or C3H response. Table 3 shows that KLH-TsF from the C3H $\rightarrow$ C57BL/6 chimaera that received C57BL/6 APC suppressed the responses of both C3H and C57BL/6. However, after adsorption to the anti-I-J^b column, the chimaeric TsF lost its suppressor effect on the $H-2^b$ response. The $H-2^b$ -restricted suppressor activity was recovered in the eluate from the column. The opposite results were

KLH-specific TsF (KLH-TsF) was prepared by freezing and thawing of thymocytes from chimaeric or non-chimaeric mice that had been prime with 200 µg of KLH twice at a 2-week interval as described elsewhere³. In some experiments, the chimaeric mice were injected intravenously twice with 2 × 10⁶ APC (anti-Thy-1-treated peritoneal exudate cells) of the host type at the same time as immunization with KLH. Peritoneal exudate cells were prepared according to the method described elsewhere²³, and treated with anti-Thy-1 and complement (C). The phenotypes of peritoneal exudate cells used were determined in a cytotoxicity assay, and over 95% were found to be Ia-positive cells, with no T-cell contamination (n Thy-1⁺, Lyt-1⁺ or Lyt-2⁺). Two weeks after the second immunization with KLH, the thymocytes derived from chimaeric mice were used to prepare KLH-TsF. In experiment 3, KLH-primed thymocytes (1 × 10⁷ ml⁻¹) derived from chimaeras that received APC of the host type, were treated with anti-H-2D^b (anti-donor) or anti-H-2K^b (anti-host) antibody plus complement, washed, then subjected to freezing and thawing for TsF preparation. KLH-TsF (25 µl, a concentration equivalent to 1 × 10⁷ thymocytes ml⁻¹) was added at the start of cultivation to spleen cell cultures (1.6 × 10⁶ per well) of C57BL/6 or C3H mice primed 4 weeks previously with 100 µg DNP-KLH or 0.1 µg ml⁻¹ DNP-OVA plus 10⁹ *Bordetella pertussis* vaccine. The cells were cultured for 5 days in a 48-well flat-bottomed plate (Costar 3548) with 0.4 ml of RPMI-1640 medium enriched with 10% FCS in the presence of 0.01 µg ml⁻¹ DNP-KLH or 0.1 µg ml⁻¹ DNP-OVA. Anti-DNP IgG PFC were enumerated by using DNP-coupled sheep erythrocyte. Numbers are the mean (±s.d.) PFC number for three cultures. ND, not determined.

KLH-TsF (100 µl, equivalent to 1.5 × 10⁷ thymocytes) from chimaeric mice that received APC of the host type (same materials as used in Table 2) was applied to and incubated with immunoadsorbent columns of anti-I-J^b or anti-I-J^k antiserum for 1 h at 4 °C. The effluent or the acid eluate (0.175 M glycine-HCl buffer, pH 3.2) was dialysed, concentrated to a final volume of 100 µl with Sephadex powder, added to a culture of DNP-KLH-primed spleen cells of C57BL/6(B6)(H-2^b) and C3H(H-2^k) mice, and tested for its suppressor activity (see Table 2). Conventions: anti-I-J antisera were used in this experiment to detect any types of I-J determinants generated in the chimaera. Values are mean number of PFC (±s.d.) for three cultures, expressed as number per 10⁶ cultured cells.

obtained when the same KLH-TsF was applied to an anti-I-J^k column. The H-2^k-restricted TsF was adsorbed to and eluted from the anti-I-J^k column, whereas the H-2^b-restricted TsF was recovered in the effluent. Similar results were obtained for KLH-TsF from the C57BL/6 → C3H chimaera that received C3H APC: the H-2^b-restricted KLH-TsF was recovered in the effluent while the H-2^k-restricted KLH-TsF was obtained in the eluate from the anti-I-J^k column. These results demonstrate that the chimaeric TsF contains two types of TsF bearing I-J of host or donor type, that is, I-J^b-TsF or I-J^k-TsF. Hence, both donor- and host-restricted Ts (anti-H-2^k and anti-H-2^b T cells), each of which produce I-J^k- or I-J^b-TsF, are generated from C3H(H-2^k) bone marrow cells under the influence of H-2^b. C57BL/6(H-2^b) bone marrow cells also produce I-J^k-TsF in the H-2^k environment, implying that I-J of the host type is generated in the chimaera. It is probable, therefore, that I-J represents the idiotype determinant on the variable part of the self-receptor of Ts, as speculated by Schrader¹⁹, and recently discussed by Kurata *et al.*²⁰ and Murphy²¹, and also that expression of the I-J phenotype on KLH-TsF is dictated by the host environment.

If the I-J is the idiotype determinant of the recognition component on TsF, several questions must be answered. First, why does the I-J on TsF or Ts receptor map in the H-2 complex? There is no definite answer to this question as yet. However, the experiments using chimaeras described in Table 2 suggest the existence of a new H-2-encoded class II-like molecule on APC. This molecule seems to be essential for the generation and clonal expansion of I-J⁺ Ts and also necessary for expression of the I-J phenotype. The molecule is apparently expressed on APC at least (Tables 2, 3), but does not seem to be identical to the known Ia molecule (that is I-A or I-E). In fact, the B10.A(5R) → C57BL/6 chimaera produces only the H-2^k-restricted TsF(I-J^k-TsF) even though B10.A(5R) and C57BL/6 mice have the I-A^b subregion in common, and I-A^b APC should be present in the chimaera (Table 2). Involvement of the I-E molecule is also excluded, because the H-2^b mice do express the I-J^b phenotype, although they are unable to express the I-E molecule²².

Second, why do Ts and TsF express I-J with H-2-haplotype specificity? If the I-J idotype is expressed on the self-recognizing structure (the I-J⁺ molecule), the I-J could be complementary to the MHC-encoded molecule on the APC so that the I-J seems to be a reflection of MHC-encoded molecule. If this is the case, the variable (V) gene repertoire of the self-receptor of Ts should be limited. In any event, the genetic identification and biochemical characterization of the molecules on APC will be important for resolving the I-J paradox.

We thank Miss K. Watanabe and H. Sudo for preparation of the manuscript. This work was supported in part by a grant-in-aid from the Ministry of Education, Culture and Science of Japan.

I-J epitopes are adaptively acquired by T cells differentiated in the chimaeric condition

Wojciech Uracz, Yoshihiro Asano, Ryo Abe & Tomio Tada

Department of Immunology, Faculty of Medicine, University of Tokyo, Tokyo 113, Japan

I-J has been defined as a locus mapped in the murine major histocompatibility complex (MHC) which encodes serological markers found primarily on the surface of suppressor T cells (Ts) and soluble suppressor factors (TsF)^{1,2}. Recent studies have, however, revealed that there is no such specialized locus within the MHC at the DNA level^{3,4}. As the existence of I-J determinants at the protein level on functional T cells, T-cell clones and hybridomas has been confirmed by several serological and biochemical studies⁵⁻⁷, this contradiction has raised serious arguments in the immunological community concerning the nature, origin and expression of I-J determinants. We have raised a number of monoclonal antibodies against the polymorphic structure of I-J molecules, and have studied the expression of I-J epitopes on T cells derived from irradiated bone marrow chimaeras in which stem cells of different genotype differentiated into T cells under the foreign host MHC environment. The results, presented here, indicate that I-J epitopes are not primarily determined by the MHC genes of the stem cells themselves, but are adaptively acquired by T cells differentiated in the chimaeric condition according to the environmental MHC phenotype. Thus, the serologically detectable I-J epitopes are found to be associated with inducible T-cell receptors recognizing self class II MHC antigens.

We have previously reported an interesting activity of anti-I-J monoclonal antibody, which was used to determine serologically the allelic forms of I-J molecules on T cells⁸. The essential findings were: (1) anti-I-J^k antibody blocks the syngeneic and allogeneic mixed lymphocyte reactions (MLRs) of H-2^k and H-2^a haplotype strains but not that of their H-2 congenic partners (this was caused by the blocking of responding T cells but not of stimulator cells). (2) In the syngeneic MLR of H-2^{k/b} F₁ T cells stimulated by F₁ or either parental strain, anti-I-J^k antibody inhibited the response to H-2^k but not to H-2^b stimulators, indicating that I-J^k epitopes are expressed only on those F₁ responder T cells recognizing H-2^k stimulator molecules but not on those responding to H-2^b stimulators. (3) The pattern of inhibition of the syngeneic and allogeneic MLRs of T cells from individual H-2^k strains by various anti-I-J^k antibodies was different under the control of as yet undetermined non-MHC background genes. Thus, the I-J epitopes were found to be associated with the MLR recognition sites of T cells, which are not determined solely by the H-2 genes but which are also influenced by unknown non-MHC genes. These results prompted us to examine the expression of I-J on T cells of irrelevant H-2 genotypic origin but differentiated in the chimaeric condition.

To determine the nature of I-J epitopes on chimaeric T cells, we also used another set of monoclonal antibodies reactive with I-region-controlled epitopes uniquely expressed on T but not on B cells⁹. These monoclonal antibodies were produced by immunizing A.TH (H-2^d) mice with I-region-incompatible A.TL (H-2ⁱ) lymphoid cells; they were selected for their specific reactivity with some functional T cells and T-cell hybridomas⁹. The antibodies were unable to react with conventional class II antigens on B cells and macrophages, but were able to precipitate a unique polypeptide of relative molecular mass 33,000 (33 K), which is apparently under the control of the I-A subregion of the H-2 complex, from a T-cell hybridoma producing an antigen-specific augmenting T-cell factor (TaF)¹⁰. The interrelationship between this polypeptide and the α and

Inhibition of MLR by the cytotoxic treatment of responder cells from normal and chimaeric mice with anti-I-J and anti-Iat antibodies. An allogeneic MLR (allo-MLR) was set up with 2.5×10^5 spleen cells as responders and an equal number of MMC-treated SJA/9 spleen cells as stimulators in RPMI 1640 medium supplemented with 10% fetal calf serum and 5×10^{-5} M 2-mercaptoethanol in 96-well flat-bottomed microtitre plates. Cells were cultured for 5 days, and DNA synthesis assessed by pulsing with $1 \mu\text{Ci}$ of ^3H -thymidine for the final 16 h. The inhibitory activity of each antibody was studied by treating responder cells for 45 min at room temperature with a 1:10 dilution of ascites fluid from BALB/c *nu/nu* mice containing the monoclonal antibody followed by incubation with a 1:10 dilution of selected rabbit complement (C) for 30 min at 37°C . After extensive washing, cells were cultured with MMC-treated stimulator cells. The mean c.p.m. for five replicate cultures was determined, and the values shown are net c.p.m. (Δ c.p.m.), calculated by subtracting the sum of the c.p.m. for stimulator and responder cultures from the c.p.m. of a mixture of the two types of cells. Per cent MLR inhibition (% Inh.) was calculated as $[1 - (\Delta\text{c.p.m. for MLR with antibody} + \text{C} / \Delta\text{c.p.m. for MLR with C alone})] \times 100$. Note that the response of C3H and B6C3F₁, but not B6, was inhibited by treatment with two of the anti-I-J antibodies (1G8 and KN34) and with two of the anti-Iat antibodies (1L9 and 2L2). The MLR of the B6C3F₁ → C3H and C3H → B6C3F₁ chimaeras was inhibited by the same four antibodies that inhibited the parental C3H response, whereas no inhibition of the MLR was observed with spleen cells from the B6C3F₁ → B6 chimaera. The MLR of the B6 → B6C3F₁ chimaera and of the fully allogeneic B6 → C3H chimaera stimulated with SJA/9 was inhibited by only two of the antibodies (2L2 and KN34). Similar, even more prominent blocking of the MLR, with the same inhibitory pattern, was observed by the simple addition of $1 \mu\text{g ml}^{-1}$ of each antibody at the start of cultivation (data not shown).

β chains of T-cell receptors is unknown. Because the epitopes detected by these antibodies are selectively expressed on T cells, and as I region apparently controls the molecule, we designated these monoclonal reagents as anti-Iat antibodies. The present experiments used anti-I-J and anti-Iat antibodies, the properties of which have been described fully elsewhere⁸⁻¹¹.

Fully allogeneic and semi-allogeneic bone marrow chimaeras were produced according to the protocol of Singer *et al.*¹². The mice were maintained for over 3 months to establish a complete chimaeric state, which was confirmed at the time of each experiment by cytotoxicity assays using appropriate anti-H-2 reagents and by the unresponsiveness to both host and donor type stimulator cells in MLR. Sera from individual chimaeric mice were also typed to confirm the immunoglobulin allotype of donor origin.

The allo-MLR was performed by culturing 2.5×10^5 spleen cells from normal or chimaeric animals with an equal number of mitomycin C (MMC)-treated spleen cells of strain SJA/9 (*H-2^s*, *Igh-1^a*) in 0.2 ml for 5 days in 96-well microtitre plates. Although anyMHC-incompatible strains can be used as stimulators, SJA/9 was selected for use because both C3H and C57BL/6 (B6) responded very well to the SJA/9 cells, and the response of C3H was found to be inhibitable by a panel of anti-I-J and anti-Iat antibodies. Three anti-I-J (1G8, IgM; 4B11, IgM; and KN34, IgG2b) and four anti-Iat (1L9, IgM; 2L2, IgG2b; 14P, IgG1; and 74L, IgG2a) monoclonal antibodies were used in the present experiment to identify the epitopes on responding T cells. Before MLR cultivation, responder cells were treated for 45 min at room temperature with a 1:10 dilution of ascites fluid from BALB/c *nu/nu* mice containing each monoclonal antibody, then incubated at 37°C for 30 min with a 1:10 dilution of selected rabbit complement. For each antibody, less than 10% of responder cells were killed by the treatment. In the blocking experiments, the globulin fraction of ascites fluid was added to the MLR at a concentration of $1 \mu\text{g ml}^{-1}$ at the start of cultivation. Cells were pulsed with $1 \mu\text{Ci}$ of ^3H -thymidine (^3H -TdR) for the final 16 h of the 5-day cultivation.

Table 1 shows the inhibition of uptake of ^3H -TdR by C3H and (B6 × C3H)_{F₁} (B6C3F₁) responder cells stimulated with MMC-treated SJA/9 spleen cells by the treatment of the responder cells with two anti-I-J (1G8 and KN34) and two anti-Iat (1L9 and 2L2) antibodies. The response of B6 cells was not inhibitable by treatment with any of these antibodies. The MLR of spleen cells derived from the B6C3F₁ → C3H chimaera was also inhibitable by all four antibodies that were effective in inhibiting the response of parental C3H. None of the mono-

clonal antibodies was effective in inhibiting the response of spleen cells from the B6C3F₁ → B6 chimaera, even though the responding cells carried an *H-2^k* determinant, as detected by cytotoxicity testing with appropriate anti-class I antibodies. Thus, the T cells of F₁ stem-cell origin were found to express I-J^k and Iat^k epitopes only when they differentiated in the environment of an *H-2^k* but not an *H-2^b* recipient.

The experiments using parental T cells transferred into F₁ chimaeras gave more definitive results. Cells responding to SJA/9 derived from C3H → B6C3F₁ chimaeras were killed by all four antibodies (1G8, KN34, 1L9 and 2L2), while those from B6 → B6C3F₁ chimaeras expressed at least two of the epitopes detected by anti-I-J^k (KN34) and anti-Iat^k (2L2). The latter finding was especially interesting, as it indicates that the T cells of *H-2^b* stem-cell origin which differentiated in the *H-2^k* environment acquired at least some of the I-J^k and Iat^k phenotypes. The parental haplotype origin of the responding T cells was always confirmed by cytotoxicity testing with appropriate anti-H-2 reagents. In the fully allogeneic chimaera, the response of the B6 → C3H chimaera was inhibitable by the antibodies 2L2 and KN34, whereas the response of the C3H → B6 chimaera was not inhibitable by any of the antibodies. The same pattern of blocking of allo-MLR was observed by adding $1 \mu\text{g ml}^{-1}$ of these antibodies to the MLR culture (data not shown), which suggested the direct association of I-J and Iat epitopes with the allorecognition site of MLR responding T cells. The results indicate that I-J^k and Iat^k epitopes on MLR responder T cells are adaptively acquired in the chimaera, where allogeneic or semi-allogeneic stem cells differentiate into mature T cells under the selective influence of environmental MHC products.

Note, however, that the responses of F₁ → C3H and C3H → F₁ chimaeras were inhibited by the same four antibodies that were effective in inhibiting the MLR of normal C3H cells responding to the same SJA/9 stimulator, whereas the responses of B6 → F₁ and B6 → C3H chimaeras to the same stimulator were inhibited by only two of the four antibodies. This result suggests that the expression of I-J and Iat epitopes on the alloreactive T cells is determined essentially by two different factors: (1) the environmental MHC products in the host under which stem cells differentiate into T cells and acquire the alloreactive repertoire, probably in the thymus; (2) possibly the non-*H-2* genomic material originally possessed by the stem cell itself. Thus, B6 stem cells differentiated into T cells in a C3H environment are unable to express all the epitopes possessed by normal C3H responder cells.

We tested the above postulate by examining the pattern of inhibition of the MLR of bone marrow chimaeras transplanted

with *H-2*-compatible stem cells having different non-*H-2* background genes. We have shown previously that the inhibition pattern of both the syngeneic and allogeneic MLR by several anti-I-J antibodies differs among *H-2^k* strains, under the control of as yet unknown non-MHC genes⁸. Therefore, we constructed bone marrow chimaeras of B10.BR→C3H, in which *H-2* is identical, whereas non-*H-2* genes are different. Table 2 compares the inhibitory patterns produced by treatment with several anti-I-J and anti-Iat antibodies of B10.BR, C3H and B10.BR→C3H chimaeric T cells responding to the same SJA/9 stimulator. Whereas the C3H response was inhibited by 1G8, KN34, 1L9 and 2L2, the response of B10.BR was inhibited by only 1G8 and 74L, reflecting the difference in non-MHC genes between these two *H-2^k* strains. Exactly the same inhibitory patterns were observed in the blocking experiment in which antibodies were simply added to the MLR culture. The chimaeric T cells of B10.BR genotype differentiated in the C3H environment showed exactly the same pattern as B10.BR cells, but not the same as C3H, indicating that the expression of I-J and Iat epitopes is genetically determined in the case of *H-2*-compatible chimaeras.

These results are of importance in understanding why I-J products are detectable by serological and biochemical means^{5-7,11,13-16}, yet no genes have been identified at the prescribed position in the MHC^{3,4}. Several recent reports have discussed possible explanations for this discrepancy: (1) the I-J molecule is a modified α or β polypeptide of a class II MHC antigen, created by post-translational modification¹⁷; (2) I-J epitopes are created via an interaction between MHC and non-MHC genes, the latter being designated as *Jt* and mapped to chromosome 4²³; and (3) I-J is not the direct product of an MHC gene but is an inducible T-cell receptor for self *I*-region products^{11,18}.

Our findings indicate the following: (1) I-J and related Iat epitopes are present at the allorecognition site of MLR responder T cells; (2) I-J^k and Iat^k epitopes are inducible on chimaeric T cells derived from strains with a different MHC genotype but differentiated in the *H-2^k* environment; (3) the expression of I-J^k and Iat^k epitopes in chimaeric conditions is determined not only by the *H-2* phenotype of the host but also by the genomic material originally possessed by the stem cells; (4) the distribution patterns of I-J and Iat epitopes are determined by as yet unknown non-*H-2* genes. Based on these findings, we believe that I-J and Iat epitopes are not the mere markers of functional T-cell subsets, as originally proposed, but are associated with inducible T-cell receptors for alloantigen whose repertoire is determined by the environmental MHC products encountered during an early stage of T-cell differentiation. It has been proposed that such allorecognition is a version of self-MHC-restriction which is determined by selection in the thymus¹⁹⁻²².

Hayes *et al.*^{23,28} have suggested that the MHC and the *Jt* locus on chromosome 4 interact to give expression of the I-J epitope, probably through glycosylation. It is, however, difficult to explain the adaptive acquisition of polymorphic epitopes by means of simple glycosylation, because the F₁→B6 and C3H→B6 chimaeras cannot express I-J^k even though the stem cells should carry both *H-2* and *Jt* genes. It is puzzling that certain I-J epitopes are not detected on B10.BR responding T cells regardless of their presence on B6→C3H chimaeric T cells. Obviously there exists an as yet unknown regulatory mechanism whereby the fine organization of I-J epitopes at T-cell receptor sites is determined. Our results do not favour the postulate that I-J is a modified α or β chain of a class II antigen¹⁷, as it is unlikely that such pleiomorphic molecules can make structural changes by adapting to the environmental class II antigens.

It has been well documented that the functional MHC-restriction specificities of T cells are adaptable, changing according to the *H-2* environment in which they undergo early differentiation in the thymus^{21,22,24-26}. Yamauchi *et al.*²⁷ demonstrated adaptive changes in the functional MHC and immunoglobulin heavy-chain variable-region restriction specificities of sup-

Table 2 Inhibition of the allo-MLR of T cells from the B10.BR→C3H chimaera by anti-I-J and anti-Iat monoclonal antibodies in comparison with B10.BR and C3H T cells

Responder cells.		B10.BR		C3H		B10.BR → C3H

Inhibition of the MLR by treatment of responder cells from normal and *H-2*-compatible chimaeric mice with anti-I-J and anti-Iat antibodies. Allo-MLRs of B10.BR, C3H and B10.BR→C3H chimaeras stimulated by MMC-treated SJA/9 spleen cells were set up as described for Table 1. Note that the MLR of B10.BR is inhibited by two antibodies (1G8 and 74L), one of which (74L) does not inhibit the MLR of C3H. The inhibitory pattern of the B10.BR→C3H chimaera is exactly the same as that of B10.BR but differs from that of C3H.

pressor factors derived from chimaeric T cells, but were unable to detect the adaptive acquisition of allogeneic I-J determinants. Here, by using monoclonal antibodies that detect the polymorphic portion of the I-J molecule, we have provided evidence that serologically detectable I-J and Iat epitopes associated with the allorecognition structure are adaptively acquired in the chimaeric condition. We have shown previously that different anti-I-J monoclonal antibodies killed T cells responding to different alloantigens, which indicates the clonal distribution of these epitopes⁸. Thus, we conclude that I-J and Iat epitopes are not directly encoded by intra-*H-2* genes but are associated with the T cells' inducible receptors for the self class II antigens that determine the restriction specificity. This explains the apparent linkage of I-J and Iat phenotypes to class II alleles. Although *I-J* has yet to be mapped within the MHC, the present results provide new insight into the T-cell receptor for self antigens, and anti-Iat reagents should be useful in defining the restriction specificities and development of T cells.

The role of IgD in the immune response has been elusive, although its predominance on the cell surface suggests a receptor function. We have shown previously that euthymic but not athymic BALB/c mice, injected with IgD before antigen, exhibit enhanced antibody responses which can be transferred by T cells^{1,2}. Isotype-specific T cells have been reported to have both upward and downward immunoregulatory effects³⁻⁵. Here we demonstrate the existence of T cells with receptors for IgD, and show that exposure to IgD *in vivo* or *in vitro* significantly increases the number of T δ cells in the spleen and lymph nodes but not in the thymus. The kinetics of T δ -cell appearance *in vivo* parallels that of the immunoenhancing effect which occurs after injection of IgD. These T δ cells are of the Lyt 1⁺2⁻ T-cell phenotype.

Recently, we have found that mice bearing IgD-secreting plasmacytomas have enhanced humoral immune responses¹. We postulated that T cells bearing receptors for IgD (T δ) mediate the increased antibody production. The potential immunoregulatory activity of such a T-cell population is underlined by the fact that most peripheral B cells carry membrane IgD⁶.

We used sheep erythrocytes (SE) coupled to IgD in a rosetting assay to enumerate IgD-specific rosette-forming cells (IgD-RFC). The effects of overnight incubation at 37 °C of normal spleen cells with either a 1:10 dilution of TEPC 1017 ascites fluid (containing ~3 mg IgD ml⁻¹) or 0.04–20 µg of purified IgD ml⁻¹ are shown in Table 1 and Fig. 1. Fresh normal BALB/c spleen cells show 5 ± 0.8% IgD-RFC (*n* = 15) (result not shown), and after incubation with medium this percentage remains essentially unchanged. In contrast, exposure to IgD for

Fig. 1 Dose-response of IgD-induced IgD-RFC. Spleen cells from BALB/c mice were incubated at 37 °C for 18 h in 1 ml of MEM containing 2% FCS without or with purified IgD as described in Table 1. Following this incubation period, cells were washed twice in MEM and then examined in the IgD-RFC assay as described in Table 1.

18 h causes the percentage RFC to increase to >25%. Similarly purified splenic T cells incubated with IgD yield >25% RF (Table 1). The absence of an increase in percentage RFC on purification of T cells after panning on anti-immunoglobulin coated dishes could be the result of selective adherence of proportion of T δ cells on the membranes of IgD-expressing cells. Overnight incubation of splenic T cells with IgM- and IgG-containing ascites does not cause an increase in IgD-RFC. Addition of IgD to the RFC assay mixture significantly reduces the number of IgD-RFC detected (Table 1), whereas addition of IgM- and IgG-containing ascites has no detectable inhibitory effect.

Using a similar *in vitro* approach, we examined the effect of exposure to IgD on various cell populations (Table 2). Where spleen cells from normal BALB/c mice show a 5–6-fold increase in the number of IgD-RFC to 28% after *in vitro* incubation with IgD, spleen cells from mice injected with IgD *in vivo* show a mean value of 30% IgD-RFC with or without additional *in vitro* exposure to IgD. The failure of these cells to respond with further increase in the percentage of IgD-RFC suggests that the 30% value represents an upper limit to the inducible level of such cells.

Table 1 Specificity of IgD-RFC induced by exposure to IgD *in vitro*

Cell source	Addition during RFC assay*		Mean % IgD-RFC ± s.e. (n) after overnight incubation with:			
	IgD	IgM + IgG	Medium alone	IgD-containing ascites fluid	Purified IgD	IgM + IgG-containing ascites fluid
Spleen cells	—	—	8 ± 0.7 (9)†‡	27 ± 1.6 (10)†	29 ± 1.9 (19)‡	6 ± 1.3 (3)
Splenic T cells	—	—	9 ± 0.8 (4)§	31 ± 3.0 (4)§	27 ± 1.2 (8)	7 ± 0.9 (6)
Splenic T cells	+	—	—	6 ± 2.5 (3)	—	—
Splenic T cells	—	+	—	30 ± 0.05 (3)	—	—

Cells were obtained from BALB/c mice. Splenic T cells were purified by negative selection by panning spleen cells on Petri dishes coated with affinity-purified goat anti-mouse immunoglobulin¹⁴. The percentage of immunoglobulin-positive cells contaminating such purified T-cell suspension following this T-cell enrichment procedure was consistently <1%. Cells (2.5×10^6) were incubated at 37 °C for 18 h in 1 ml of minimal essential medium (MEM, Gibco) containing 2% fetal calf serum (FCS). Where indicated, the medium was supplemented with TEPC 1017 ascites fluid (3 mg IgD ml⁻¹, 0.04–20 µg ml⁻¹ purified IgD (pooled data from Fig. 1), or 10% IgM + IgG-containing ascites fluid obtained from mice bearing the MOPC 104E plasmacytoma. Following this incubation period, cells were washed twice and the cell concentration readjusted to 2.5×10^6 ml⁻¹ in MEM + 2% FCS. The cells were then used in the RFC assay. IgD was affinity-purified from ascites fluid taken from BALB/c mice bearing the IgD-secreting myeloma TEPC 1017, according to methods described previously¹, then it was coupled to SE using the CrCl₃ coupling method¹. Coupling of IgD to SE was confirmed by both positive haemagglutination and indirect immunofluorescence assays using a rabbit anti-mouse Ig antiserum. IgD-RFC were enumerated using a modified method of Chen *et al.*¹⁶. Briefly, 0.2 ml of 1% IgD-SE was mixed with 0.1 ml of assay cells (2.5×10^5) at 37 °C for 15 min. Cells were then centrifuged at 500 r.p.m. (200g) for 5 min and incubated further at 4 °C for 45 min or overnight. Immediately before scoring RFC, the lymphocytes were stained using 0.025 ml of a 1% toluidine blue solution. Lymphocytes surrounded by over three indicator cells were scored as rosettes and the result expressed as % RFC. In each experiment, the percentage of cells forming rosettes with SE was determined and always found to be <2%.

* Where indicated, IgD-containing, or IgM plus IgG-containing ascites fluid was added to samples to a final concentration of 6%.

† For medium alone compared with IgD-containing ascites fluid, *P* < 0.0001.

‡ *P* < 0.0001; § *P* = 0.001; || *P* < 0.001, ¶ *P* = 0.001.

Table 2 *In vitro* induction of T δ cells following overnight incubation with IgD-containing ascites fluid

Cell source	<i>In vivo</i> pretreatment	Medium alone	Mean % IgD-RFC $\pm$ s.e. following overnight incubation with IgD-containing ascites fluid	P
Spleen cells	—	8 $\pm$ 1.2	28 $\pm$ 1.9	<0.0001
Spleen cells	TNP-KLH*	11 $\pm$ 1.7	30 $\pm$ 2.4	0.001
Spleen cells	IgD†	30 $\pm$ 1.7	31 $\pm$ 2.4	NS
Splenic T cells	—	8 $\pm$ 0.7	30 $\pm$ 2.9	0.01
Splenic Lyt 1 ⁺ 2 ⁺ T cells	—	—	40 $\pm$ 2.1	<0.0001‡
Splenic L3T4 ⁺ T cells	—	—	8 $\pm$ 1.9	NS‡
Splenic B cells	—	5 $\pm$ 0.7	8 $\pm$ 1.4	NS
Lymph node cells	—	5 $\pm$ 0.9	42 $\pm$ 3.9	0.006
Thymocytes	—	5 $\pm$ 0.3	8 $\pm$ 1.5	NS
C B20 spleen cells	—	8 $\pm$ 0.5	31 $\pm$ 2.2	<0.0001

Cells were incubated in MEM+2% FCS with or without IgD-containing ascites fluid as described in Table 1. The results are the means for 3–6 assays. Except for C B20 spleen cells, the cells were obtained from BALB/c mice. Splenic T cells were purified as described in Table 1. Using purified T-cell suspensions as the starting population, Lyt 1⁺2⁺ and L3T4⁺ T-cell subpopulations were isolated by complement-mediated cytotoxicity using the monoclonal antibodies anti-Lyt 2.2 (19/178), provided by Dr U Hammerling (Sloan-Kettering Institute, New York), and anti-L3T4 (GK1.5)¹⁷, obtained from Dr F. Fitch (University of Chicago, Illinois) respectively. Splenic B cells were purified by complement-mediated cytotoxicity of T cells using a cocktail containing anti-Thy-1.2 (6.80), provided by Dr U Hammerling, anti-Lyt 1.2 (C3PO) provided by Dr J. Klein (Max Planck Institute, Tübingen) and anti-L3T4 (GK1.5).

* Mice were injected intravenously (i.v.) with 100 μ g TNP-KLH 12 and 5 days before the day of assay.

† Mice were injected i.p. with 0.5 ml of IgD-containing ascites fluid 7 and 1 day before the day of assay.

‡ P values determined by comparing the mean % IgD-RFC following overnight incubation with IgD with the mean % RFC for splenic T cells following overnight incubation in medium alone

The T-cell lineage of the IgD-RFC was investigated further by examining the ability of specific T-cell subsets to form rosettes with IgD-SE. As shown in Table 2, isolated Lyt 1⁺2⁺ but not L3T4⁺ T cells yield significantly increased numbers of IgD-RFC after overnight incubation with IgD. These results suggest that most, if not all, the IgD-RFC are Lyt 1⁺2⁺, L3T4⁺ T cells—that is, they have the helper cell phenotype. However, the possibility that some RFC may be Lyt 2⁺ cannot be excluded; further studies are needed to determine whether the incidence of IgD-RFC in Lyt 2⁺ cells can be increased if they are exposed to IgD in the presence of other cell types. Marcelletti and Katz⁷ have recently reported that optimal induction of IgE-binding, Lyt 2⁺ T δ cells is dependent on the presence of B cells. The majority of T α and T β cells induced by exposure to IgA and IgE respectively, are Lyt 2⁺ (refs 8, 9).

The percentage of IgD-RFC in lymph-node cell suspensions also increases (from 5 to 42%) after incubation with IgD. In contrast to peripheral T cells, however, thymocytes show only background levels (5–8%) of IgD-RFC before and after *in vitro* exposure to IgD. Similarly, when isolated splenic B cells are incubated overnight with IgD, no significant increase above background numbers of IgD-RFC is seen.

The induction of IgD-RFC is not allotype-specific as spleen cells from C.B20 mice, which express the *b* allotype of IgD, are as responsive as BALB/c spleen cells to TEPC 1017-derived IgD of allotype *a*. In addition, C.B20 mice bearing the TEPC 1017 plasmacytoma show a significant enhancement of the 6-day primary response to trinitrophenyl-keyhole limpet haemocyanin (TNP-KLH) (523 $\pm$ 134% of the control for 19S plaque-forming cells (PFC) and 341 $\pm$ 141% of control for 7S PFC).

Although these data established that exposure to IgD *in vivo* and *in vitro* causes the appearance of IgD-RFC, the phenotype of the *in vivo*-induced RFC remained to be determined. Table

Fig. 2 *a*, Kinetics of IgD-induced enhancement of antibody response to TNP-KLH. Results are presented as % of control responses ($\pm$ s.e.). The geometric means of responses in control mice for 19S and 7S PFC per spleen (100%) are shown above the bars. BALB/c mice were injected with 0.5 ml of IgD-containing ascites fluid on the days indicated ($n=3-11$). Mice were primed on day 0 with 100 μ g of TNP-KLH and their anti-TNP PFC responses were measured 5 days later. Anti-TNP splenic PFC were assayed by the slide modification of the technique of Jerne *et al.*¹⁸. TNP-SE were prepared using the method described by Rittenberg and Pratt¹⁹. IgG-producing cells (that is, 7S responses) were developed with rabbit anti-mouse immunoglobulin in the complement and goat anti- μ in the agar. *b*, Kinetics of appearance of T δ cells after i.p. injection of IgD-containing ascites fluid. BALB/c mice were injected with 0.5 ml of IgD-containing ascites fluid on the days indicated. Spleen cells were obtained on day 0 and the percentage of IgD-RFC determined ($n=3-6$).

3 shows that ~30% IgD-RFC are obtained in both unfractionated and Lyt 1⁺2⁺ splenic T cells following injections of IgD. The induction of IgD-RFC *in vivo* also parallels the *in vitro* results in that >30% RFC are found in lymph nodes and only 3% RFC in thymus. The results in Tables 2 and 3 suggest strongly that injection of antigen also causes a significant increase in the number of splenic IgD-RFC. Further characterization of these RFC is underway.

The kinetics of appearance of T δ cells after intraperitoneal (i.p.) injection of IgD was studied in parallel with the humoral immune responsiveness of similarly treated mice (Fig. 2). The responses of animals injected with IgD on day -1, -5 or -7 or on both days +1 or -7 were higher than those of untreated mice. In contrast, the responses of mice injected with IgD 3 days before injection of antigen were not augmented. The presence or absence of augmentation of the PFC response is in complete agreement with the presence or absence of increased numbers of T δ cells in the spleen. However, the magnitude and kinetics of the two phenomena differ somewhat. The percentage of T δ cells rises to a near maximum within 1 day after IgD injection, falls to background levels by day 3 and then rises again to maximal levels by day 5. The percentage of T δ cells found in the spleens 1 day after a second injection of IgD is as high as after the first injection. However, the magnitude of the PFC response induced after two injections of IgD is much greater than at any time after a single injection. These findings suggest strongly that T δ cells are at least as readily induced as T cells bearing Fc receptors for other immunoglobulin isotypes^{8,10}, and that T δ cells have an augmenting effect on the 19S and 7S antibody responses. The observation that maximal augmentation of immune responses *in vivo* requires two injections, whereas maximal numbers of T δ cells are observed after a single injection of IgD, may reflect a ceiling effect with respect to the percentage of splenic T cells capable of expressing receptors for IgD. It is also possible that individual T δ cells either express more receptors for IgD or become more responsive to target B cells after repeated exposure to IgD.

Table 3 Phenotype and tissue distribution of T δ cells induced *in vivo*

Cell source	<i>In vivo</i> pretreatment with IgD- containing ascites fluid	Mean % IgD-RFC $\pm$ s.e. (n)	P
Spleen cells	+	23 $\pm$ 1.4 (8)	<0.0001
	—	5 $\pm$ 0.8 (6)	
Splenic T cells	+	30 $\pm$ 4.7 (5)	0.02
	—	4 $\pm$ 0.4 (4)	
Lyt 1 ⁺ 2 ⁺ splenic T cells	+	27 $\pm$ 1.3 (5)	<0.0005
	—	5 $\pm$ 0.3 (3)	
Lymph node cells	+	32 $\pm$ 2.5 (5)	<0.005
	—	12 $\pm$ 1.3 (4)	
Thymocytes	+	3 $\pm$ 0.8 (4)	NS
	—	5 $\pm$ 0.5 (4)	
TNP-KLH-primed spleen cells	—	12 $\pm$ 1.2 (7)	<0.005
Unprimed spleen cells	—	5 $\pm$ 0.6 (7)	

Cells were obtained from BALB/c mice. Splenic T cells and Lyt 1⁺2⁺ splenic T cells were purified as described in Tables 1 and 2. Where indicated, spleen cells were obtained from BALB/c mice immunized with 100 μ g TNP-KLH 5 days before the day of assay. Where indicated, mice were injected twice (i.p.) with 0.5 ml of IgD-containing ascites fluid 7 and 1 days before the day of assay.

Results from other studies show that augmentation of the humoral immune response in normal mice can be achieved by transfer of unfractionated spleen cells, unfractionated T cells² or purified Lyt 1⁺2⁺ T cells from donors preinjected with IgD¹¹. The mechanism of action of these IgD-induced T-helper cells has not yet been established, but, in the absence of polyclonal B-cell activation¹, it is expected that interaction of antigen with IgD on the surface of the B cell activates T δ cells, which then exert their augmenting effect. Whether, as suggested previously¹, this effect is mediated through down-regulation of IgD synthesis, a known consequence of B-cell activation by antigen or mitogen^{12,13}, or through the release of a soluble mediator, remains to be established. It is of interest to speculate that the small but significant increase in T δ cell number which occurs after injection of antigen is the result of stimulation by antigen-IgD complexes. Our demonstration of IgD-rosetting T cells provides evidence for the existence of a mechanism in which T-cell help is given to all IgD-positive B cells in an antigen-dependent though not antigen-specific fashion.

Platelet secretory products inhibit lipoprotein metabolism in macrophages

David R. Phillips, Kay Arnold & Thomas L. Innerarity

Gladstone Foundation Laboratories for Cardiovascular Disease, Department of Pathology and Cardiovascular Research Institute, University of California, San Francisco, California 94140-0608, USA

Macrophages possess a receptor that binds low-density lipoproteins (LDL) containing lysine residues modified by acetylation (Ac LDL), acetoacetylation (AcAc LDL) or malondialdehyde treatment^{1–3}. This receptor (referred to as the Ac LDL receptor or scavenger receptor) internalizes the bound lipoprotein. As a consequence, massive amounts of cholesteryl esters accumulate so that macrophages in culture resemble foam cells found in atherosclerotic lesions^{4,5}. In an effort to identify an unmodified mammalian macromolecule that binds to the Ac LDL receptor, we investigated whether platelet secretory products affect the receptor-mediated endocytosis of chemically modified lipoproteins. Platelets are a potential source of such activity because they exist in close association with foam cells in developing atherosclerotic lesions^{6,7}. Our study demonstrates that human blood platelets secrete a product that inhibits the binding and uptake of AcAc LDL by mouse peritoneal macrophages and the subsequent accumulation of cholesteryl esters. This is the first indication that an endogenous macromolecule interacts with Ac LDL receptor on macrophages.

Platelet secretory products, obtained from platelets of freshly drawn human blood (see Fig. 1 legend), inhibited the cellular uptake of ¹²⁵I-AcAc LDL (Fig. 1a) and the subsequent degradation of the iodinated lipoprotein to trichloroacetic acid-soluble material (Fig. 1b) by mouse peritoneal macrophages. The secretory products also inhibited the uptake and degradation of ¹²⁵I-Ac LDL (data not shown). Preincubation of the macrophages with 100 μ g ml⁻¹ platelet secretory protein for 16 h followed by washing did not affect the subsequent cellular uptake and degradation of ¹²⁵I-AcAc LDL, indicating that the platelet products did not inhibit the uptake by down-regulating the Ac LDL receptor. Previous studies have shown that cultured macrophages bind AcAc LDL at 4 °C, a temperature at which internalization and subsequent proteolytic degradation do not occur⁵. We found that at 4 °C, the secretory products from platelets inhibited ¹²⁵I-AcAc LDL binding to macrophages; 59 μ g ml⁻¹ secretory products were needed for 50% inhibition (data not shown). The platelet-derived inhibitor demonstrated specificity for interaction with the Ac LDL receptor in that it had little effect on the uptake and degradation of ¹²⁵I-labelled β -migrating very-low-density lipoproteins (β -VLDL) (Fig. 1a, b, respectively) by the β -VLDL receptor on mouse peritoneal macrophages⁵. Similarly, the platelet secretory products, at concentrations shown to inhibit the uptake and degradation of ¹²⁵I-AcAc LDL by macrophages, had little effect on the uptake of ¹²⁵I-LDL by cultured human fibroblasts (data not shown). Thus, platelet secretory products act to inhibit selectively the binding, uptake and degradation of ¹²⁵I-AcAc LDL by macrophages.

The cholesterol liberated following receptor-mediated uptake of AcAc LDL by macrophages is re-esterified in the cytoplasm⁵. Cholesteryl ester synthesis can be readily assayed by including ¹⁴C-oleate in the culture medium and measuring the formation of radiolabelled cholesteryl oleate¹. We found that the platelet secretory products inhibited the AcAc LDL-induced formation of cholesteryl ¹⁴C-oleate by mouse peritoneal macrophages (Fig. 2). Therefore, one functional consequence of the platelet-derived inhibitory activity is the prevention of AcAc LDL-mediated cholesteryl ester formation and accumulation.

Agents and conditions known to affect the release of platelet secretory products were examined to determine their ability to release the inhibitor of AcAc LDL degradation (Fig. 3). Whereas the thrombin-induced secretory products inhibited the degradation of ¹²⁵I-AcAc LDL by mouse peritoneal macrophages, little

Fig. 1 Effect of platelet secretory products on the uptake (a) and degradation (b) of ^{125}I -AcAc LDL (●) or ^{125}I - β -VLDL (□) by mouse peritoneal macrophages.

Methods. Secretory products were obtained from the platelets of freshly drawn human blood. Platelets were collected and washed as described previously¹⁴ and, except where noted, suspended to a concentration of $3\text{--}5 \times 10^9$ platelets per ml in a solution containing 1 mM EDTA, 10 mM HEPES and 0.15 M NaCl pH 7.4 (EHS buffer). The washed platelets were induced to secrete by treatment with 0.5 U ml^{-1} human α -thrombin (a gift from Dr John Fenton III) for 5 min at ambient temperature, after which time the thrombin was inhibited by the addition of hirudin at 1 U ml^{-1} . The platelets were then removed by centrifugation at $10,000g$ for 15 min at 4°C and discarded. The supernatant, containing the secretory products, was dialysed against EHS buffer, concentrated by filtration (YM-10 filter, Amicon Corporation) and frozen until needed. Mouse peritoneal macrophages were collected from unstimulated mice and dispensed into 16-mm Petri dishes (5×10^5 cells per dish) as described previously¹⁵. The dishes were incubated for 2 h at 37°C and washed three times with Dulbecco's modified Eagle's medium (DMEM) to remove non-adherent cells. The cultured macrophages were incubated overnight in DMEM containing 20% fetal calf serum and washed once with DMEM before use. To measure the uptake and degradation of the labelled protein, each 16-mm dish of macrophages received 0.3 ml DMEM containing 10% human lipoprotein-deficient serum, the indicated concentrations of platelet secretory products and either $1 \mu\text{g ml}^{-1}$ ^{125}I - β -VLDL or $1 \mu\text{g ml}^{-1}$ ^{125}I -AcAc LDL. The dishes were then incubated for 5 h at 37°C . The amount of ^{125}I -labelled protein taken up and degraded by the cells was determined as described previously¹⁵. Procedures for the isolation and iodination of the AcAc LDL and β -VLDL and the modification of the LDL by acetoacetylation have also been described elsewhere¹⁵.

inhibitory activity was detected when platelets were incubated without thrombin, when thrombin was mixed with hirudin before addition to platelets, or when platelets were preincubated with prostacyclin. This demonstrates that the proteolytic activity of thrombin and the functional activity of platelets are required for the expression of the inhibitory activity. Two additional platelet agonists, the Ca^{2+} ionophore A23187 and collagen, were found to release an amount of inhibitor equivalent to that released by thrombin. These findings suggest that the inhibitor is secreted from the platelet storage organelles⁸, probably α -granules, which are the primary source of protein secreted in response to the three agonists tested⁹. Because the concentration of secretory products used for the experiment in Fig. 3 was equivalent to that induced from platelets at 2.5×10^8 per ml, we conclude that the inhibitor is secreted in sufficient concentrations at physiological platelet counts ($3\text{--}4 \times 10^8$ platelets per ml) to affect the binding activity of the Ac LDL receptor on macrophages.

Initial attempts to characterize the inhibitor of AcAc LDL uptake and degradation showed that the activity from thrombin-activated platelets persisted after samples were frozen and thawed twice. This activity was not affected by incubating the platelets for 30 min at temperatures between 4°C and 70°C and did not pass through filters (XM 100, Amicon Corporation) with an exclusion limit of relative molecular mass 100,000 (data not shown). From these observations, we tentatively conclude that the inhibitor is a stable secretory product of platelets and is

Fig. 2 Inhibition of AcAc LDL-mediated cholesterol esterification in mouse peritoneal macrophages by platelet secretory products. Each 16-mm Petri dish received 0.3 ml of DMEM containing 0.2 mM ^{14}C -oleate (oleate albumin complex), $4 \mu\text{g}$ protein per ml of AcAc LDL, and the indicated concentration of platelet secretory products. After incubation for 16 h at 37°C , the cellular content of ^{14}C -oleate was determined by TLC¹⁵.

Fig. 3 Platelet secretion is required for the expression of the inhibitor of ^{125}I -AcAc LDL degradation by macrophages. Platelets from normal volunteers were isolated and suspended in EHS buffer (10^9 platelets per ml). Aliquots of 1.5 ml were treated as indicated for 5 min at ambient temperature and centrifuged at $1,000g$ for 15 min to sediment the platelets. In some cases, hirudin was added immediately after the 5-min incubation. The supernatant was removed, centrifuged at $15,000g$ for 2 min and assayed for inhibition of ^{125}I -AcAc LDL degradation as described in Fig. 1 legend, using a 1:4 dilution of the platelet supernatant. Conditions: thrombin, 0.5 U ml^{-1} ; control, no addition; thrombin plus hirudin, thrombin (0.5 U ml^{-1}) preincubated with hirudin (1 U ml^{-1}) before addition to platelets; PGI_2 , platelets preincubated with 50 nM prostacyclin for 10 min at ambient temperature before addition of thrombin; A23187, $1 \mu\text{M}$ A23187; collagen, $20 \mu\text{g ml}^{-1}$ collagen.

associated with a macromolecule(s) of high relative molecular mass.

Although the physiological function of a platelet-derived inhibitor of the Ac LDL receptor on macrophages is unknown, we suggest two possibilities. One is that this inhibitor regulates accumulation of cholesterol in these cells. In atherosclerotic lesions, cholesteryl esters accumulate in macrophage-derived foam cells^{5-7,10}. Although the mechanism of lipid uptake is unknown, it has been suggested that LDL can be modified *in vivo* so that they can be recognized by the Ac LDL receptor^{3,5,11,12}. If such modifications cause cholesterol accumulation in foam cells, the platelet secretory products released at the site of an atherosclerotic lesion could serve to dampen the rate of cholesterol accumulation. An alternative possibility is that the platelet-derived inhibitor could activate macrophages. Binding of ligands to the Ac LDL receptor on macrophages induces the secretion of several proteins, including the Ca^{2+} -dependent neutral protease, a plasminogen activator and a cytolytic factor¹³. The inhibitor from platelets may induce similar secretions.

Vascular endothelial cells have a central role in various pathophysiological responses such as acute inflammation, wound healing and atherogenesis. The anatomical position of endothelial cells between blood leukocytes and the surrounding vascular smooth muscle cells or stromal fibroblasts may intensify and focus the effects of released endothelial cell products. Endothelial cells in culture produce a platelet-derived growth factor (PDGF)-like mitogen¹. PDGF purified from platelets is a basic protein with an apparent relative molecular mass (M_r) of ~30,000 (reviewed in refs 2, 3) and is believed to comprise two polypeptide chains, PDGF-A and PDGF-B⁴ (also referred to as PDGF-1 and PDGF-2; refs 5, 6). Sequence analysis of PDGF B chain has revealed a striking homology with the predicted sequence of p28^{sis}, the transforming protein of simian sarcoma virus^{4,6,7}. *sis*-Homologous transcripts have been detected by Northern blot analysis of RNA from cultured endothelial cells⁸. However, there are no structural data available on either the protein product or the messenger RNA to establish the identity of the endothelial-derived mitogen with either chain of PDGF. Here we report the isolation and complete sequence analysis of a *sis*-homologous complementary DNA clone from human endothelial cells, providing an opportunity to study the structure of *sis* as transcribed by a normal (untransformed) cell. Our results establish that normal human endothelial cells in culture express the B chain of PDGF, and that endothelial-derived PDGF B chain is synthesized as a predicted precursor polypeptide of M_r 27,281.

A prominent *v-sis* hybridizing band of about 3.5 kilobases (kb) was detected in Northern blots of cytoplasmic RNA from cultured human umbilical vein endothelial (HUVE) cells⁹, a simian virus 40 (SV40)-transformed endothelial cell line¹⁰ and a bovine aortic⁹ endothelial cell strain (Fig. 1A). These bands are of a similar size to that of an RNA species isolated from a human osteosarcoma cell line (HOS), previously reported to be ~4.2 kb¹¹. A diffuse minor band of 2.7 kb was also observed. No *v-sis* hybridizing bands were detected in RNA preparations from cultured human dermal fibroblasts or from a B-lymphoblastoid cell line.

Fig. 1 A, Expression of *c-sis* in cultured vascular endothelial cells. *a-c*, 50 μ g each of cytoplasmic RNA from a human osteosarcoma cell line (HOS), cultured bovine aortic endothelial cells (BAEC) and an SV40-transformed endothelial cell line, respectively; *d, e*, 10 and 20 μ g, respectively, of cytoplasmic RNA from human umbilical vein endothelial cells; *f, g*, 50 μ g of cytoplasmic RNA from each of two strains of human dermal fibroblasts; *h*, 5 μ g of poly(A)⁺ RNA from the lymphoblastoid line LB. The molecular sizes (kb) of ³²P 3'-end-labelled *Hind*III-digested phage λ DNA, processed in parallel with the RNA samples, are indicated on the left. B, Hybridization probes from the 5'-untranslated region of the B2-1 clone and the B-chain coding region identify the same transcript in RNA from HUVE cells. In each lane, 5 μ g of poly(A)⁺ RNA from HUVE cells was analysed by RNA blotting techniques³⁰. Following transfer to nitrocellulose, the lanes were separated and independently analysed with: *a*, a coding-region probe (*v-sis*) or *b*, a probe from the 5'-untranslated (5'-UT) region (an *Eco*RI-*Hin*FI restriction fragment, nucleotides 1-280).

Methods. Total cytoplasmic or poly(A)⁺ RNA was prepared as described elsewhere³⁰. The RNAs were denatured with formaldehyde and electrophoresed in a 1% agarose gel, transferred to nitrocellulose, and probed with nick-translated cDNA inserts as described elsewhere³⁰. The filter was washed in 0.5 $\times$ SSC at 68 $^{\circ}$ C and exposed to film as described previously³¹.

To determine the nucleotide sequence of the *sis*-homologous 3.5-kb transcript, a cDNA corresponding to the endothelial cell mRNA was cloned and its primary structure determined. Restriction mapping and Southern blot hybridization with the *v-sis* probe were used to establish the overlapping orientation of two cDNA clones from the random hexanucleotide (B2-1) and the oligo(dT)-primed (A1-6) libraries (Fig. 2). The 5' clone (B2-1) contains the *v-sis*-homologous region and extends 860 base pairs (bp) farther 5' than a previously described cDNA clone derived from the HUT 102 neoplastic T-cell line¹². The 3' clone A1-6 ends just 3' to an *Sst*I site located ~500 bp upstream from the polyadenylation site (based on a restriction map comparison with the HUT 102 cDNA). Together these clones span 3.2 kb and by inference account for most of the 3.5-kb *sis*-homologous transcript observed on Northern blots of HUVE cytoplasmic RNA.

Sequence analysis of the B2-1 clone confirms the presence of a region of *v-sis* homology containing an open reading frame that encodes the B chain of PDGF; it also reveals an exceptionally long 5'-untranslated region (Fig. 3A). The *v-sis*-homologous region begins at position 1,053 and continues to the 3' end of this clone. Over the region encoding the B-chain protein sequence, the HUVE cDNA clone is identical in nucleotide sequence both to the previously sequenced clone from the HUT 102 T lymphoma cell line¹² and to the exons of the normal human *c-sis* gene^{4,13,14}. A potential initiation codon, ATG (position 989), is in-phase with the B-chain open reading frame and the coding region would extend 723 bp before terminating at position 1,712. The predicted primary translation product for the B chain is 241 amino acids long (M_r 27,281). The sequence in Fig. 2 must encode the entire precursor for the B chain because, as in HUT 102, an in-frame translational stop codon is located 117 bp upstream (position 872) from the open reading frame.

Located at the N-terminus of the predicted precursor is a hydrophobic sequence (bases 998-1,036) encoding residues 4-16, which may serve as a signal for secretion. The protein encoded by *v-sis* contains a similar signal sequence derived from the retroviral envelope gene. Construction of deletion mutants in the putative *v-sis* signal region was correlated with the loss of transforming ability¹⁵. The B chain of PDGF, as isolated from platelets, is known to be both cysteine-rich and highly basic^{2,3}. The predicted precursor is interesting in that the putative amino-terminal 'pro' region has no cysteines and is markedly acidic. In contrast, the extreme carboxy terminus, which also appears to be removed proteolytically from mature B chain⁴, contains cysteine residues and is highly basic.

The B2-1 HUVE clone extends 293 bp upstream from the reported 5' end of the genomic sequence¹⁶. To confirm that the 5' HUVE cDNA region is actually part of the *c-sis* gene, a probe encoding nucleotides 1-280 was hybridized to HUVE poly(A)⁺ RNA and compared with a probe defining the coding region

Fig. 3 A, Nucleotide sequence of the B2-1 cDNA clone of the PDGF B chain. The nucleotide sequence is shown, with the predicted amino acids (standard three-letter code) below the respective codons of the B-chain open reading frame. Mature PDGF B chain, isolated from platelets, appears to extend from an N-terminal serine (nucleotides 1,232-1,235) to a C-terminal threonine (nucleotides 1,556-1,558), indicated by single asterisks. The three ATG codons located 5' to the B-chain open reading frame are underlined, as is the TGA codon in-frame with the translational start site for the B chain. The 5' end of the presently reported genomic sequence¹⁶ is indicated by the solid arrowhead; the 5' end of the previously reported HUT 102 cDNA sequence¹² is coincident with the underlined TGA codon. Nucleotides 1,743 to 1,891 (indicated by Δ) in the 3'-untranslated region of the endothelial cDNA clone are not found in *v-sis*, but are also present in the HUT 102 cDNA¹², suggesting that alternative splicing may occur in the 3'-untranslated region, or that a deletion event occurred in the woolly monkey genome (the presumed source of *v-sis*). **B, Distribution of translation termination codons in human endothelial cells.** The positive codons are indicated (vertical lines) orientations. The four 5'-proximal of the text are indicated by boxes; the fourth most 5'-proximal ATG codon

[illegible]

Fig. 2 (Left) Restriction map and sequencing strategy. Restriction maps of overlapping A1-6 (oligo(dT) library) and B2-1 (random library) cDNA clones were determined by Southern blotting with a *v-sis* probe and restriction analysis. The location of the B-chain precursor is indicated by arrows on the B2-1 clone; the region of the cDNA corresponding to the protein sequence⁴⁻⁷ of PDGF is indicated by an open box. The sequencing strategy is outlined below the B2-1 restriction map. Arrows indicate the direction of sequencing using the Maxam-Gilbert³² chemical degradation method. Asterisks indicate that the *EcoRI* sites on the B2-1 clone have been added during the cloning process.

Methods. HUVE cells were cultured as described³³. Construction of the cDNA libraries is presented in detail elsewhere³⁴. Briefly, cells were collected and total RNA prepared by lysis in buffer containing 6 M guanidine-HCl. Poly(A)⁺ mRNA was isolated from total endothelial cell RNA by oligo(dT)-cellulose column chromatography³⁰; cDNA was synthesized by the method of Okayama and Berg³⁵ as modified by Gubler and Hoffman³⁶, using oligo(dT)₁₂₋₁₈ as primer for first strand synthesis (oligo(dT) library). A second cDNA pool was synthesized using a random mixture of hexanucleotides as primer for the first strand synthesis (random library). Recombinant λ gt11 phage clones³⁸ containing inserts homologous to c-sis were isolated from the cDNA libraries by screening with the 950-bp *Xba*I-*Pst*II fragment of the retroviral transforming gene v-sis²⁵. The probe was radiolabelled using an oligonucleotide primer labelling method³⁷.

(*v-sis*) by Northern blotting. The two probes hybridize to an identical 3.5-kb transcript (Fig. 1B). Furthermore, both probes also hybridize to the same 24-kb *Eco*RI fragment in a genomic Southern blot analysis (not shown). In the region of the overlap, the only major differences between the published 5' genomic sequence¹⁶ and the HEC cDNA sequence are the eight nucleotides at the 5' end of the genomic clone (cDNA position 292-299). These nucleotides were probably added during construction of the genomic library¹⁷ and the 5' continuation of the cDNA is transcribed, at least in part, from the continuation of the present 5' exon.

The 5'-untranslated region of the PDGF B-chain transcript is unusually long (at least 983 bp). Most 5'-untranslated regions are less than ~150 bp long¹⁸, although there are notable exceptions. Specifically, *c-myc*, another cellular homologue of a retroviral transforming gene (whose expression is activated by PDGF¹⁹), has a 550-bp 5'-untranslated region²⁰. Another mitogen, murine preproepidermal growth factor, also has a long (353 bp) 5'-untranslated region²¹, and genomic sequence analysis suggests that the insulin-like growth factor II precursor has ~1 kb of 5'-untranslated region²². The transcript is also unusual in that translation begins at the fourth most 5'-proximal ATG codon (position 989, Fig. 3B). Recently, a consensus sequence (CC(A or G)CCATGG) for translation initiation has been defined¹⁸, in which purine nucleotides three positions upstream and one position downstream from the ATG are particularly important²³. Only the ATG in the B-chain reading frame meets both these criteria (TCGGCATGA). The second open reading frame could encode a protein of *M_r* 12,529. A search of the GenBank sequence database revealed no significantly (non-*sis*-related) homologous sequences. In addition, analysis of codon usage²⁴ suggests that this open reading frame is unlikely to encode a translated protein.

The extreme length of the 5'-untranslated region and the presence of three other ATG codons may be important in the physiological regulation of PDGF expression. Interestingly, both the naturally transforming retrovirus^{15,25} and the experimentally transforming HUT 102 cDNA²⁶ clone delete the other upstream ATG codons. Similarly, when *c-sis* genomic constructions lacking the complete 5'-untranslated region are placed under the transcriptional control of a retroviral long terminal repeat, the constructs acquire high-titre transforming activity¹⁶.

PDGF as purified from human platelets contains a second polypeptide that is less homologous to *v-sis* (A chain)⁴, and it is thought that human PDGF is predominantly a 1:1 disulphide-linked heterodimer of A and B chains^{2,3}. The cDNA sequence reported here establishes that the A chain does not arise from the same precursor polypeptide as the B chain of PDGF. The data presented here do not, however, exclude the possibility that *c-sis* encodes the A chain of PDGF, as it could be generated by differential splicing. It is unknown whether endothelial cell-derived PDGF-like mitogen is also an A/B chain mixture, or whether endothelial cells even synthesize the A chain of PDGF. It is possible that the endothelial mitogen is a B-chain homodimer, as has been suggested for porcine PDGF²⁷. The eventual generation of complete PDGF A-chain and B-chain cDNA clones may elucidate both the functional interactions between these polypeptides and the potential issue of coordinate expression. Finally, the 5' cDNA sequence information presented here should assist in locating the true 5' end of the human *c-sis* gene and, with it, possible sequences that regulate endothelial cell PDGF expression *in situ*^{8,28}. Such information may be critical in understanding the role of endothelium in pathological processes.

Part of this work was reported previously in abstract form²⁹. We thank Keith Robbins for the *v-sis* probe; James Rheinwald and Michael Gimbrone for the dermal fibroblast and endothelial cultures, respectively; Temple Smith for assistance with the comparative sequence analysis; Kay Case and Ethel Gordon for technical assistance; Robin Lee for secretarial assistance; and Jack Strominger, Michael Gimbrone and Ramzi Cotran for support and helpful discussions. This work was supported by grants from the NIH. Light-regulated and organ-specific expression of a wheat Cab gene in transgenic tobacco

Gayle Lamppa*, Ferenc Nagy & Nam-Hai Chua†

Laboratory of Plant Molecular Biology, Rockefeller University, 1230 York Avenue, New York, New York 10021-6399, USA

Many of our most important crop plants are monocotyledons, including wheat, corn, rice and barley. No routine transformation system for monocotyledons has been reported, such as the Ti-mediated gene transfer system for dicotyledons facilitated by *Agrobacterium tumefaciens*¹⁻³. Indirect evidence suggests that Ti-plasmid DNA is transferred into and expressed in *A. tumefaciens*-infected wound tissues of plants from Liliaceae and Amaryllidaceae^{4,5}, but these observations have not been extended to monocotyledons of greatest agricultural importance. Regeneration of monocotyledons is usually blocked at the callus stage, further complicating the possibility of exploring the regulated expression of their genes, and thus preventing identification of the regulatory domains of monocotyledonous genes in a homologous nuclear background. To circumvent these difficulties, we investigated whether monocotyledonous genes can be expressed and correctly regulated in dicotyledons. We have introduced a wheat gene (*whAB1.6*)⁶ encoding the major chlorophyll *a/b* binding protein (Cab) of the light-harvesting complex into the genomes of tobacco (*Nicotiana tabacum* SR1) and petunia (*Petunia hybrida*) via a Ti-DNA-mediated gene transfer system which allows the transformed cells to regenerate into whole plants⁷. Here we report for the first time the light-regulated and organ-specific expression of a monocotyledonous gene in transgenic dicotyledonous plants.

A 6.5-kilobase (kb) wheat genomic fragment containing the Cab gene (*whAB1.6*) was ligated into the *Cla*I site of the vector pMON145 (Fig. 1)⁸ and the construct was mobilized into a 'disarmed' *A. tumefaciens* derivative (GV3111SE)⁷. After co-cultivation of *A. tumefaciens* and protoplasts of *N. tabacum* SR1, transformed cells were identified by their resistance to kanamycin at 100 µg ml⁻¹ (ref. 1). Plants were regenerated from transformed calli according to Marton *et al.*⁹.

† To whom correspondence should be addressed.

Fig. 1 Wheat Cab gene construction used for transformation. An 8.7-kb wheat genomic fragment containing the Cab gene, *whAB1.6* (ref. 6), was subcloned into pBR322 to yield the construct *whAB8.7*. Digestion of *whAB8.7* with *Cla*I releases a 6.5-kb fragment containing the entire wheat Cab protein-coding sequence, 4.4 kb upstream of the transcription start site, 800 bp beyond the stop codon and 250 bp of pBR322 at the 3' end. The 6.5-kb *Cla*I fragment was inserted into the *Cla*I site of pMON145, which has been described in detail elsewhere⁸. pMON145 contains the *NOS-NptII* fusion gene, a region homologous to *A. tumefaciens* Ti-DNA, a region of pBR322, spectinomycin (*spc*) and streptomycin (*str*) resistance genes. It also contains a 400-bp segment (*Pvu*I/*Sst*II) of the pTiT37 *Hind*III-23 fragment which includes the pTiT37 T-DNA right border⁸.

Methods. *Escherichia coli* strain LE392 was transformed with the *whAB6.5*/pMON145 plasmid construct, and colonies were selected for *spc* and *str* resistance. The *whAB6.5*/pMON145 construct was introduced by a triparental cross⁸ into a disarmed *A. tumefaciens* derivative (GV3111SE) containing a modified Ti-plasmid lacking phytohormone biosynthetic genes and TL-DNA right border⁷.

Northern blot analysis shows that in wheat the accumulation of Cab transcripts is strongly dependent on light (Fig. 2a). Using as a probe a labelled *Bgl*II/*Sma*I fragment, which encodes the carboxy-terminus of the mature Cab protein⁶, the amount of Cab transcripts in etiolated leaves is at least 20 times less than in green leaves. When etiolated wheat plants are transferred to the light for 24 h, leaf Cab messenger RNA increases to the amount that accumulates in leaves from plants grown in a normal light/dark cycle. The Northern blot analysis does not discriminate among transcripts from different members (at least seven) of the wheat Cab multigene family⁶.

To establish whether expression of *whAB1.6* is light-dependent, a gene-specific *Bam*HI/*Mst*I fragment was hybridized to the same RNAs and the products analysed by the *S*₁ nuclease assay¹⁰. The *Bam*HI/*Mst*I probe is 305 nucleotides long, and yields an *S*₁-resistant product of 169 nucleotides which includes the *whAB1.6* non-translated leader and extends 102 nucleotides into the Cab coding region. Figure 3a shows that this product is found only after light stimulation. We estimate that the *whAB1.6* transcript level increases at least 20-fold in going from the dark to the light.

To determine whether the wheat Cab gene is expressed in leaves of transgenic tobacco, and also whether it is light-regulated, we isolated RNA from leaves pooled from 10 individual transgenic tobacco clones. The plants were (1) grown under a light/dark, 16/8-h photoperiodic cycle, (2) transferred to the dark for 7 days and (3) transferred to the dark and then re-exposed to continuous light for 24 h. Blots of these RNAs were hybridized with the labelled *Bgl*II/*Sma*I fragment from *whAB1.6* (ref. 6), which does not cross-hybridize with the endogenous tobacco Cab mRNA in stringent conditions (Fig.

Fig. 2 Northern blot analysis of transcripts from wheat and transgenic tobacco leaves. *a*, Total RNA (10 µg) from wheat leaves of plants grown in the light (L) for 8 days in a 16/8-h light/dark cycle (lane 1), etiolated (E) plants grown in the dark (lane 2), or etiolated plants transferred to the light (E→L) for 24 h (lane 3). *b*, RNA (10 µg) from leaves of transgenic tobacco plants grown in a 16/8-h light/dark cycle from the callus stage (lane 1), young plants grown in the dark for 7 days (lane 2) and young plants transferred from the dark to the light (D→L) for 24 h (lane 3). Lane 4 shows a wheat leaf RNA (10 µg) control included in the tobacco analysis. *c*, Poly(A) RNAs were prepared¹¹ from leaves of transgenic tobacco plants. Lanes 1–3 are the same as lanes 1–3 in *b*. Each lane contained 1 µg of poly(A) RNA.

Methods. Total RNA was isolated from either wheat or tobacco leaves using the guanidinium thiocyanate procedure¹⁹, and Northern blots were analysed according to Carmichael and McMaster²⁰. The blots for *a* and *b* were hybridized to a ³²P-labelled *Bgl*II/*Sma*I fragment (10⁸ c.p.m. per µg) of 383 bp and encoding the carboxy-terminus of the Cab protein⁶. Hybridization was performed in 50% formamide, 2×Denhardt's, 50 mM NaPO₄, and 5×SSC, 100 µg ml⁻¹ calf thymus DNA at 46 °C. In these conditions the fragment does not hybridize with tobacco RNA (see Fig. 4a, lane 7). The blot for *c* was hybridized to a nick-translated probe containing the coding region of *NptII* in the same conditions.

Methods. Total RNA was isolated from either wheat or tobacco leaves using the guanidinium thiocyanate procedure¹⁹, and Northern blots were analysed according to Carmichael and McMaster²⁰. The blots for *a* and *b* were hybridized to a ³²P-labelled *Bgl*II/*Sma*I fragment (10⁸ c.p.m. per µg) of 383 bp and encoding the carboxy-terminus of the Cab protein⁶. Hybridization was performed in 50% formamide, 2×Denhardt's, 50 mM NaPO₄, and 5×SSC, 100 µg ml⁻¹ calf thymus DNA at 46 °C. In these conditions the fragment does not hybridize with tobacco RNA (see Fig. 4a, lane 7). The blot for *c* was hybridized to a nick-translated probe containing the coding region of *NptII* in the same conditions.

4a, lane 7). Figure 2b demonstrates that the wheat Cab gene is expressed in light-grown tobacco leaves at a level at least 4–10-fold higher than in leaves of dark-adapted plants (compare Fig. 2b, lanes 1, 2, and Fig. 4b, lanes 1, 2). On re-illumination, the wheat Cab mRNA level is often more than double the level found in plants grown in a 16/8-h light/dark photoperiodic cycle. The reason for this mRNA overproduction is being investigated. The wheat Cab mRNA level is reduced 4-fold in tobacco plants transferred to the dark and then increases 10-fold when plants are re-illuminated (Fig. 2b). To determine whether the reduction of the wheat Cab transcript level in the dark is selective, we prepared poly(A) RNAs¹¹ and analysed the mRNA levels for the chimaeric gene comprised of the nopaline synthase (*NOS*) promoter fused to the neomycin phosphotransferase (*NptII*) coding sequence (*NOS-NptII*). Figure 2c shows that the *NOS-NptII* transcript is indeed present in the dark-adapted plants and in plants returned to the light. The *NOS-NptII* gene has been demonstrated to be constitutively expressed in all tissues of plants which are kanamycin-resistant¹², including those transferred to the dark (F.N., unpublished results).

The Northern blot analyses demonstrate the presence of the wheat Cab transcript in transgenic tobacco leaves and that it is the same size (1,100 nucleotides) as in wheat. Furthermore, the wheat Cab mRNA can be recovered in the tobacco poly(A) RNA fraction (data not shown). These results suggest that the wheat Cab transcript is correctly processed and polyadenylated. To ascertain if accurate transcription initiation also occurs, transcripts from transgenic tobacco were mapped by *S*₁ nuclease protection. A 5' end-labelled *whAB1.6* *Bam*HI/*Mst*I fragment, described above, was hybridized with total leaf RNA from both light- and dark-grown plants, and the products were analysed alongside those obtained using wheat leaf RNA. A 169-nucleotide *S*₁-resistant product is obtained with either the wheat or the transgenic tobacco leaf RNAs (Fig. 3b). We conclude that transcription of the wheat Cab gene begins correctly in tobacco, and confirm with the *S*₁ nuclease results that the level of the wheat Cab transcript is also controlled by light in the transgenic plants. The transcripts are present in transgenic tobacco at ~10–25% the level found in wheat leaves (Fig. 3, compare lanes 1, 3, 5). These values do not reflect the absolute expression level of the wheat Cab gene because its copy numbers in the transgenic tobacco plants have not been determined. In contrast, the *NOS*-

Fig. 3 S_1 nuclease analysis of light-regulated wheat Cab transcripts in wheat and transgenic tobacco. *a*, S_1 products using wheat RNAs. The same RNAs (10 μ g per lane) for lanes 1, 2 and 3 were used as described in Fig. 2a legend. *b*, S_1 products using transgenic tobacco RNAs. Lanes 1–3 are analogous to the lanes in Fig. 2b. Lane 4 shows hybridization of the *Bam*HI/*Mst*I fragment to untransformed tobacco RNA, and lane 5, a wheat leaf RNA control reaction. Each lane contained 10 μ g RNA. The band of high relative molecular mass (M_r) (305 nucleotides) corresponds to the undigested probe. The S_1 nuclease-resistant band at 169 nucleotides is caused by hybridization of the probe to the *whAB1.6*-specific transcript and the low- M_r bands (lane 5) represent hybrids between the probe and transcripts of other wheat Cab genes that show limited sequence homology to *whAB1.6* in the non-translated leader RNA region⁶.

Methods. RNAs were prepared from wheat and tobacco as described for Fig. 2. A 5'-end-labelled *Bam*HI/*Mst*I fragment from *whAB1.6* (ref. 6) was hybridized with 25 μ g of total RNA in 40 mM PIPES (pH 6.4), 1 mM EDTA, 0.4 M NaCl, 80% formamide. Samples were incubated for 4 h at 50 °C, digested with 30 units of S_1 nuclease (BRL) at 37 °C, in 0.3 M NaCl, 4.5 mM ZnCl₂, 5 mM sodium acetate and 20 μ g ml⁻¹ salmon sperm DNA¹⁰, and extracted with phenol/chloroform and ether. S_1 nuclease-resistant products were precipitated with 25 μ g of *E. coli* transfer RNA and aliquots were analysed on 8% acrylamide gels.

NptII transcripts can be detected only in the poly(A) RNA fraction (Fig. 2), which requires a ~100-fold enrichment step.

whAB1.6 is active in wheat leaves, requires light for activation (Fig. 3a) and is not expressed in roots⁶. To establish if the wheat Cab gene construct also contains sufficient information for organ-specific expression in the transgenic plants, RNAs were isolated from different organs of transgenic tobacco. We found that the wheat Cab gene is expressed predominantly in tobacco leaves by Northern blot analyses (Fig. 4a) and by S_1 nuclease protection assays (data not shown). In some RNA preparations the wheat Cab mRNA can be detected in tobacco stems at a lower level (~5–10-fold) than in leaves; expression continues to be light-regulated (Fig. 4b). We have also transferred the wheat Cab gene into *P. hybrida* and obtained accurate transcriptional initiation and light-regulated and organ-specific expression (data not shown).

Our results demonstrate that a wheat Cab gene is accurately transcribed and selectively expressed in transgenic tobacco and petunia. This is the first report of regulated expression of any Cab gene in transgenic plants. Our observations indicate that the dicotyledonous nuclear transcription apparatus recognizes the relevant regulatory sequences of the wheat Cab gene, and that the necessary information for gene activation is contained within a wheat genomic fragment which begins 4.4 kb 5' to the transcription initiation site and extends 850 base pairs (bp) beyond the Cab protein translation stop codon. Furthermore, the wheat Cab transcripts are polyadenylated (data not shown) and stable in tobacco and petunia cells.

A zein gene from maize is expressed in sunflower calli¹³, although it is not known whether organ-specificity of the zein gene will be retained in regenerated plants. Our finding that the wheat Cab gene functions with specificity in two dicotyledonous plants suggests that at least some dicotyledonous genes may show regulated expression in monocotyledons.

Fig. 4 Organ-specific expression of the wheat Cab gene in tobacco. *a*, Northern blot analysis. Lane 1, wheat leaves; lanes 2–5, leaves, stems, petals and roots, respectively, from transgenic tobacco plants grown under a 16/8-h light/dark photoperiod; lane 6, leaves of transgenic tobacco plants transferred to the dark for 7 days; lane 7, leaves of untransformed tobacco plants. Each lane contained 10 μ g RNA. *b*, S_1 nuclease protection assays. Lanes 1, 3, leaves and stems of transgenic tobacco grown under a 16/18-h light/dark photoperiod; lanes 2, 4, leaves and stems of transgenic tobacco transferred to the dark for 7 days. Each lane contained 10 μ g RNA.

Methods. RNAs were extracted from different plant organs¹⁹ and analysed by Northern blot hybridizations²⁰ or S_1 nuclease protection assays¹⁰. See Figs 2 and 3 legends for details.

The *cis*-acting sequences that control the wheat Cab gene have not been characterized. That the regulatory sequences of the wheat Cab gene functions with apparent fidelity in tobacco and petunia renders their identification feasible by combining *in vitro* mutagenesis and the *A. tumefaciens*-mediated gene transfer system, as has been done for the genes encoding the ribulose 1,5-bisphosphate carboxylase small subunit of pea (*rbcS*)^{14,21} and the 35S promoter of cauliflower mosaic virus¹². Our immediate goal is to compare the DNA sequences used for the light-dependent expression of the Cab¹⁵ and *rbcS* (refs 16, 17) genes. In peas the accumulation of Cab and *rbcS* transcripts begins at different red-light fluencies¹⁸, which suggests that the genes encoding key components of the chloroplast photosynthetic machinery are selectively responsive to light and regulated independently during shoot development.

UNIVERSITY OF WARWICK

POSTDOCTORAL PROTEIN CHEMIST/BIOCHEMIST

Applications are invited for a suitably experienced person to work on a project concerning the identification and structural characterisation of the cell binding sites on the plant toxin ricin as part of a group modifying the functional properties of ricin by site directed mutagenesis of cDNA clones. The position is funded by the SERC for three years commencing October 1985 on the research 1A scale: £7,520 to £12,150.

Applicants should send a cv with the names and addresses of two referees to the Executive Officer, Department of Biological Sciences, University of Warwick, Coventry, CV4 7AL, quoting Ref. JML/LMR. For formal enquiries to Dr J.M. Lord (ext 6098) or Dr L.M. Roberts (ext 58) on 0203-24011.

(7458)A

UNIVERSITY OF ST ANDREW'S

Department of Anatomy and Experimental Pathology

CELL/DEVELOPMENTAL BIOLOGIST

Applications are invited for a post doctoral research assistant to work with Dr J McLachlan on the control of cell division in embryonic limb development. This appointment is funded by the Medical Research Council and is for a period of 2 years from October 1st 1985. Experience in tissue culture techniques is desirable.

Starting salary within range £7,520 - £8,920 per annum plus USS.

Applications with the names of 3 referees should be sent by 13th September 1985 to Dr J C McLachlan, Department of Anatomy and Experimental Pathology, The University, St Andrew's, Fife KY16 9TS.

(7481)A

IMPERIAL CANCER RESEARCH FUND

Biostatistician in the

DEPARTMENT OF MATHEMATICS, STATISTICS AND EPIDEMIOLOGY

A BIOSTATISTICIAN

with a recent PhD in statistics and an interest in biomedical applications is needed to develop methodology in the area of rank regression for censored and uncensored survival data. The candidate will be expected to extend the methodology developed in this department and elsewhere, to validate new methods via simulation and example, and to develop computer programmes to implement these methods.

The appointment is tenable for three years in the salary range £8,920 to £11,205 plus £1,365 London Weighting. For further details write or telephone Ms S M Hurley, Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2 on 01-242 0200 ext 305 quoting reference 106/85.

(7469)A

MEDICAL RESEARCH COUNCIL

National Institute for Medical Research

Laboratory of Cell Propagation

A THREE-YEAR POSTDOCTORAL POSITION

is available immediately for work on molecular genetic aspects of the yeast cell cycle. Previous experience in molecular biology is essential. Further information can be obtained from Dr D H Williamson (Tel. 01-959-3666).

The salary will be in the range of £8,920 — £10,720 per annum, plus £1,233 London allowance and superannuation provision.

Applicants should send cv and the names of two referees to the Assistant Director, National Institute for Medical Research, The Ridgeway, Mill Hill, London NW7 1AA by 20 September, quoting reference CP/1.

(7468)A

Imperial Chemical Industries PLC Agricultural Division Biological Products Business

Experimental Analytical Biochemist

ICI Agricultural Division has a vacancy for an Experimental Analytical Biochemist within its Biological Products Business Research Group. The Biochemist will join a small team employing chromatographic techniques, particularly High Performance Liquid Chromatography, to the solution of analytical problems. The majority of the work will be in support of research project groups covering a wide range of biochemical topics. Applicants must, therefore, be innovative, respond well to challenge and be capable of solving development problems rapidly and efficiently.

Applicants should possess a good honours degree in biochemistry or chemistry and be able to demonstrate a comprehensive knowledge of chromatographic processes. The ability to apply this knowledge in a biochemical research environment is essential.

ICI Agricultural Division is situated in Billingham, which is part of the Teesside conurbation. A range of attractive housing is available, communications are very good and there is close proximity to areas of natural beauty such as the North Yorkshire Moors National Park and the Yorkshire Dales.

Remuneration will be commensurate with qualifications and experience. The Company operates house purchase, profit sharing and contributory pension schemes and offers financial assistance towards removal expenses.

Applications giving details of age, qualifications and experience should be sent as soon as possible to:

**Mr M.A.J.W. Pegg, Personnel Department, Imperial Chemical Industries PLC,
Agricultural Division, PO Box No 1, Billingham, Cleveland. TS23 1LB.**

ICARDA

المركز الدولي للبحوث الزراعية في المناطق الجافة

International Center for Agricultural Research in the Dry Areas

FOOD LEGUME CROP MICROBIOLOGIST

The International Center for Agricultural Research in the Dry Areas (ICARDA), with head quarters in Aleppo, Syria, invites applications for the position of a Microbiologist in the Food Legume Improvement Program (FLIP). The Microbiologist will conduct research within a multidisciplinary team in the FLIP on rhizobiology with the ultimate aim of providing the symbiotic nitrogen fixation in the dry land agriculture cropping systems through lentils, chickpeas and faba beans.

RESPONSIBILITIES

1. To study naturalized populations of *Rhizobium* spp, undertake *Rhizobium* strain selection and testing for suitability as inoculants, establish *Rhizobium* strain collection and use it in collaboration with legume breeders, in *Rhizobium* strain x host genotype studies for improved biological nitrogen fixation, and study long term persistence of the *Rhizobium* strains in field environments. To develop suitable inoculants and inoculation techniques for field use in dry areas.
2. To work closely with the agronomists and crop-physiologists in the FLIP and Farming Systems Program in studying the biological nitrogen fixation in field experiments evaluating novel production techniques and genotypes and long term rotational effects.
3. To strengthen contacts with national programs and help to enhance their efforts on symbiotic nitrogen fixation studies. Towards this end, to conduct special training programs in rhizobiology and to participate in the general food legume residential training courses.
4. To establish effective collaboration with other Centers of Excellence to augment the local rhizobiological research effort at ICARDA.

QUALIFICATIONS

A Ph.D in microbiology with at least 5 years experience of research in rhizobiology. Specialisation in the field of *Rhizobium* ecology would be desirable. Experience of working in developing countries with lentil, faba bean or chickpea would be considered desirable, and previous involvement in training activities would be useful. An essential prerequisite is competence in spoken and written English, and a knowledge of Arabic and/or French would be valuable.

CONDITIONS OF APPOINTMENT

The candidate would be based in Aleppo, North Syria and would be responsible to the Leader of the Food Legume Improvement Program. The candidate is entitled to an international tax-free salary based on background and experience; use of car; allowance towards housing; annual home leave; non-contributory medical insurance scheme; pension fund.

APPLICATION

Candidates should send 2 copies of curriculum vitae and names of 3 referees by airmail quoting reference FLIP/2/85, to:

Personnel Officer,
ICARDA,
PO Box 5466, ALEPPO, SYRIA.

Applications should be received by 30 September 1985

(W2141)A

SWINBURNE

Institute of Technology

AUSTRALIA

Lecturer in Biophysics

Position No. 1423B

Applications are invited for the position of Lecturer in Biophysics in the Department of Physics.

The successful applicant will participate in the teaching of Neurosciences within the undergraduate Biophysics programme together with the Postgraduate Diploma of Biomedical Instrumentation and the Masters programme.

The successful applicant will also be expected to participate in the research activities undertaken within the Physics Department and the Swinburne Centre for Applied Neurosciences. These include: selective attention and the visual evoked potential, visual evoked potentials in anaesthesia and intensive care unit instrumentation systems.

Qualifications and Experience:

A higher degree together with Neurosciences research experience in Biophysics, Clinical Physiology, Biomedical Engineering or equivalent is highly desirable. Teaching experience will be considered in making the appointment.

Tenure: This appointment will be a three year contract appointment after an initial probationary period of twelve months, with the possibility of renewal for a further three year period.

Salary: In the range Lecturer III level \$A22,614 - \$A25,905 per annum.

Closing Date: 27 September 1985.

Further information may be obtained from Dr. R. B. Silberstein, Head, Department of Physics, telephone Melbourne Australia 819 8273 or by writing to the address below for a Schedule of Duties.

Applications, in duplicate, including the names and addresses of three referees should be sent to:

**The Staff Officer, Swinburne,
P.O. Box 218, Hawthorn,
Victoria, 3122 Australia.**

A division of Swinburne Ltd.
Incorporated in Victoria
**AN EQUAL OPPORTUNITY
EMPLOYER**

DIRECTOR OF SCIENCE

The RP Foundation Fighting Blindness seeks a highly qualified individual as Director of Science.

Requirements include a doctorate in science, continuing interest in new developments in science, experience in grants administration and strong skills in writing and public speaking for lay and medical audiences. Previous experience in visual science helpful. Position has responsibilities in 2 areas: Research and Foundation Affairs.

Salary and benefits are commensurate with experience and responsibilities.

E.O.E. Applicants should send curriculum vitae and bibliography plus references to: Robert Gray, Ex. Dir., RP Foundation Fighting

RESEARCH TECHNICIAN

position open at research institute in La Jolla, California (San Diego area). Tissue culture experience necessary.

Apply with references to Box NW159, c/o Nature, 65 Bleecker Street, New York, NY10012.

(NW159)A

UNIVERSITY OF OXFORD Postdoctoral Research Position in Physics

A Postdoctoral position is available in the field of electron tunneling and non-equilibrium superconductivity with the goal of developing sensitive particle detectors for solar neutrino detection.

Applicants should have experience in device fabrication and low temperature physics. The appointment is for three years. Applicants should send a curriculum vitae and names of two referees to Dr N E Booth, Department of Nuclear Physics, Keble Road, Oxford, telephone (0865) 59911, as soon as possible.

Have you got the right chemistry?

Protein chemists experienced in the purification and physico-chemical analysis of proteins and antigens.

Recombinant DNA scientists experienced in cloning DNA fragments into plasmid vectors and nucleic acid isolation from mammalian genes.

Immunologists experienced in the development of enzyme-antibody conjugates and investigation into new immunoassay techniques.

Molecular geneticists experienced in gene identification, design of synthetic oligonucleotide probes and hybridisation techniques.

Cell biologists experienced in cell physiology, tissue culture and hybridoma - monoclonal antibody technology.

(7471)A

ICI is currently going through a period of major diversification and expansion into the medical diagnostics field with the establishment of the new ICI Diagnostics Group. Backed by substantial scientific and financial resources, the new group is pursuing a broad strategy embracing in-house research, product licensing and collaborative projects designed to make the company a major force in diagnostics.

Shown here is the range of scientific personnel we seek to join a new and dynamic research team involved in the development of nucleic acid - and immunoassay - based diagnostics for medical applications. Emphasis will be strongly based on the design of new diagnostics and the use of non-isotopic detection technology.

We are interested in applicants holding a good first degree or suitable equivalent qualifications, and those holding a Ph.D with, preferably, postdoctoral experience. Candidates should have a broad interest in the diagnostics field together with a flexible and adaptable approach to research areas geared to the market place. This will require a rare combination of both research and practical interest in the development of non-isotopic nucleic acid and immunoassay systems.

In return, we offer excellent technical facilities in attractive 'Greenfield' surroundings, opportunities for rapid career progression as the group expands, highly competitive salaries and conditions and a generous relocation package.

We intend to hold a series of regional meetings during September when selected applicants will be invited to find out more about our move into medical diagnostics.

Those who wish to take advantage of this exciting opportunity should send details of their career to date to Dr Trevor Twose, R & D Manager.

ICI Diagnostics Group

Stuart House, 50 Alderley Road,
Wilmslow, Cheshire SK9 1RE, UK.
Telephone. 0625 522022

VIROLOGY RESEARCH

Coopers Animal Health was formed by the merger of the worldwide interests of ICI and The Wellcome Foundation. The New Zealand company is located at Upper Hutt, 40 km north of Wellington and has a proud track record of success, in research and in the market place.

We wish to recruit suitably qualified virologists for the two positions of Head of Department and Research Scientist.

The Department is principally concerned with developing vaccines against viral diseases of veterinary importance in both large and small animal species. Therefore, in addition to a suitable background in virology, it would be of considerable advantage for an applicant to possess some additional applied research experience in these or related fields.

Successful applicants will also be encouraged to develop close working relationships with Government and other research establishments within New Zealand.

Whilst these are permanent positions, short or medium term appointments would be considered.

A competitive remuneration package, including an attractive salary which is subject to a regular merit review will be negotiated to reflect the significance of these positions to our research programme. Assistance will also be provided on travel and relocation expenses.

Please write enclosing a detailed curriculum vitae outlining your suitability for the position in which you are interested to —

John Rainey
Manager — Personnel Division

Coopers Animal Health NZ Limited

33 Whakatiki Street
Upper Hutt
New Zealand

(W2138)A

UNIVERSITY OF EAST ANGLIA Norwich LECTURESHIP IN SEDIMENTOLOGICAL GEOCHEMISTRY

Applications are invited for a lectureship in Sedimentary Geochemistry in the School of Environmental Sciences, starting from a date to be agreed between 1 January and September 1986. Salary will be on lecturer scale £7,520 — £14,925 p.a. (under review) plus U benefits.

Applications (three copies) which should contain a full curriculum vitae including exact date of birth, together with the names and addresses of three persons to whom reference may be made, should be lodged with the Establishment Officer, University of East Anglia, Norwich NR4 7TJ (telephone 0603 56161 ext 2126) from whom further particulars may be obtained, not later than 14 October 1985. No forms of application issued.

(7447)A

MOLECULAR BIOLOGIST

Tenure-track position at the assistant professor level for molecular biologist. Applicant must have at least 2 years postdoctoral experience and demonstrated accomplishment in eukaryote gene expression studies. Expertise in recombinant DNA technology essential. Ph.D. or M.D. Send curriculum vitae, a statement of research interest, and the names and addresses of 3 references to: Dr. Ralf Weichseleum, Professor Chairman, Dept. of Radiatic Oncology, Biological Sciences Division, The University of Chicago, Box 440, 5841 Maryland Ave., Chicago, IL 60637. An Affirmative Action Equal Opportunity Employer (NW1874)A

Faculty Position available, tenure-track, in molecular genetics, with a special interest in membranes. Applicants should have research background in recombinant DNA technology (preferably also in somatic cell genetics) and working knowledge of membrane proteins. M.D. and/or Ph.D. in appropriate field required. Successful candidate will hold tenure-track appointment (Assistant or Associate Professor, depending upon qualifications) in Department of Physiology and Molecular Biophysics at Baylor College of Medicine. Joint appointments in relevant academic departments also possible. Laboratory space and basic equipment provided and initial laboratory support available. Successful candidate will devote majority of his/her effort to establishing and maintaining an independent research program related to the main interests of the Department. The Department is building a strong program in membrane biophysics with expertise in electrophysiology, membrane biochemistry, reconstitution, and modelling. **Send vita, a brief description of past and present research experience, and names of three or more references to**

Dr. A. M. Brown, Incoming Chairman,
Physiology and Molecular Biophysics Department

Baylor College of Medicine,
One Baylor Plaza,
Houston, Texas 77030.

FACULTES UNIVERSITAIRES NOTRE-DAME DE LA PAIX A NAMUR

DEPARTMENT OF BIOLOGY

1) ASSISTANT PROFESSOR POSITION

The candidate must be acquainted with plant biotechnology and specialized in protoplast fusion. He will have to develop the research in this field and will have some teaching courses in plant physiology and related area.

2) ASSISTANT OF HIGH QUALIFICATION

The candidate will have a minimum of a Ph.D. in the field of Botany.

He will develop the research in plant ecology in association with the laboratory of ecology of soil water.

He will be in charge of some courses in plant ecology.

Applications forms should be sent to the Recteur of the Facultés Universitaires, rue de Bruxelles 61, B-5000 NAMUR, BELGIUM. Closing date for application: 30 September 1985.

(W206)A

CENTER FOR ADVANCED RESEARCH IN BIOTECHNOLOGY

The University of Maryland and the National Bureau of Standards have jointly established the Center for Advanced Research in Biotechnology (CARB) to provide a unique forum for collaborative research among academic, government and industrial scientists. CARB's research facility is being constructed at the Shady Grove Life Science Center in Rockville, Maryland in close proximity to the NIH, the FDA, the USDA and at the heart of one of the nation's major centers of commercial biotechnology development.

CARB will initially focus on establishing what is expected to be the world's finest facility for the determination and analysis of the structure of macromolecules. The goals of CARB's research are to radically reduce the time and effort required to determine the atomic structure of proteins and to effectively model and predict their properties. This focused thrust will help build the foundation for the rapidly emerging field of protein engineering.

Toward this end, CARB will integrate a multidisciplinary team of scientists and engineers with state-of-the-art instrumentation and facilities, some of which will truly be one of a kind. CARB will draw upon the considerable expertise at NBS in physical and chemical measurement technology and will have access to unique research facilities including the research reactor's neutron diffraction facility and NBS's new CYBER 205 supercomputer. CARB will house scientists from the University of Maryland and the National Bureau of Standards as well as a large population of visiting scholars and industrial fellows, postdoctoral investigators and graduate students.

CARB is seeking **SENIOR RESEARCH SCIENTISTS** to staff research programs in the following areas. Senior Research Scientists should have an established research record in relevant disciplines and a demonstrated ability to obtain research support. Successful candidates will generally qualify for joint, tenure-track appointments in an appropriate department of the University of Maryland. Salary and rank will be commensurate with training and experience.

RESEARCH PROGRAMS

PROTEIN CRYSTALLIZATION has as its goal the development of general methodology and instrumentation for the routine and rapid growth of high-quality, single crystals of macromolecules and macromolecular complexes suitable for x-ray and neutron diffraction analysis. CARB will strive to develop a science of macromolecular crystallization from detailed studies of lattice interactions in protein crystals and development of methods for the real-time analysis and control of crystal growth. Novel application of site-directed mutagenesis for the preparation of heavy atom derivatives will be investigated. Methods for the growth of two-dimensional crystals will also be developed including monolayer and epitaxial approaches. In addition, the solid-state properties of protein crystals will be investigated.

X-RAY AND NEUTRON DIFFRACTION will include projects in all aspects of the crystallographic process with a target of reducing the time required to solve the structure of a new protein to a matter of weeks. Projects will include development of improved area detector systems and software, development of a tunable x-ray source for anomalous scattering methods, and development of automated map-fitting tools and refinement methods.

HIGH-FIELD 2D NMR will focus on determining the solution structure of macromolecules and will include instrument development work (1500 MHz) with particular emphasis on automated data reduction and resonance assignment.

ELECTRON MICROSCOPY will focus exclusively on three-dimensional studies of macromolecules and will include development of a scanning tunneling microscope for these applications.

MOLECULAR MODELING will include applications of supercomputers, multiprocessors and expert systems to molecular modeling development of an extensive macromolecular structure database for protein engineering and molecular graphics.

For additional information or to submit a resume contact:

The University of Maryland and the National Bureau of Standards are Equal Opportunity/Affirmative Action Employers.

(NW155)A

THE UNIVERSITY OF MARYLAND

The Sandoz Institute for Medical Research Gower Place, London WC1

The Sandoz Institute for Medical Research is concerned with basic research on drugs which affect the nervous system. A multidisciplinary group of about 50 scientists and technicians are employed at the institute, which is situated within University College London. The institute

staff have close links with research groups within the University, and there are ample opportunities for collaboration. Applications are invited for two post-doctoral fellowships tenable for one year in the first instance, with a possibility of continuation for one further year.

1. Neuroimmunology

The appointee will be involved in the generation and exploitation of monoclonal antibodies to membrane receptors, under the direction of Dr J. N. Wood.

As part of this work, methods to generate monoclonal antibodies of predetermined specificity will be developed.

2. Sensory neurophysiology

The project will be concerned with the relationship between sensory neuropeptides and the regulation of spinal reflex excitability. This is a joint project between the Sandoz Institute and the Cerebral Functions Research Group at University College London directed by Professor P. D. Wall. The Post-Doctoral Fellow will be based at the Sandoz Institute.

but will be expected to collaborate actively with Professor Wall's group. The project will involve analysis of the peptide content of different types of sensory nerve, study of the transport of antibodies within sensory neurones and of the physiological effects produced, and investigation of the effects of putative sensory mediators on spinal reflexes.

Applicants should have experience in immunocytochemistry and radioimmunoassay, as well as a strong interest in neurophysiology and a willingness to participate in neurophysiological experiments. The salary range for both positions will be £10,000-£12,000 p.a., depending on age and experience.

Applicants should send a full curriculum vitae, and the names of two referees to Miss A. Giles, Sandoz Institute for Medical Research, 5 Gower Place, London WC1E 6BN. Closing date: 30th September 1985.

(7440)A

UNIVERSITY OF EDINBURGH DEPARTMENT OF BACTERIOLOGY

Virus Diagnostic Laboratory RESEARCH FELLOW

Applications are invited from a suitably qualified Postdoctoral Graduate in Biochemical, or Biological Sciences, to help in the development of a reference laboratory service for the diagnosis of infection with human T lymphotropic viruses.

The candidate would be expected to develop methods for the measurement of antibody as well as methods for the detection of virus.

The post is for one year with possibility of extension for a further year. Salary will be on the grade research scale (£7,520 — £12,000) with placement according to age and experience.

Applications by letter, including CV and the names of two referees should be sent to the Personnel Office, University of Edinburgh, South Bridge, Edinburgh EH1 1SU, not later than 12th September 1985.

Further particulars can be obtained from Dr J. F. Pleather and Dr E. Edmond, Department of Bacteriology, Medical School, Teviot Place, Edinburgh EH8 9AG (Tel 031 1011 Ext 2484 or 2251).

Please quote reference No 527 (7459).

Protein Chemist

American Cyanamid requires the services of a Protein Chemist at the Ph.D. level to assist in developing our biotechnology program at the Agricultural Research Division in Princeton, N.J.

The remuneration will be competitive, commensurate with applicant's experience.

Interested candidates are invited to submit a full curriculum vitae, a list of publications, and the names and addresses of three references to the Employment Office.

(NW157)A

University of Massachusetts Medical School interdepartmental program in Environmental Health Sciences has available a tenure-track position in either Pharmacology or Pathology. Preferred areas of general research interest include Mutagenesis/Carcinogenesis or Inhalation Pulmonary Toxicology.

The University of Massachusetts Medical School seeks to recruit a tenure-track faculty member to join several of its faculty in continuing to develop the above interdepartmental program. The appointment may begin as early as the fall of the 1985-86 academic year. The appointee will be accorded considerable institutional resources and be expected to pursue an independent research program and to participate, in the context of an interdepartmental program, in service, medical education, and/or the education of graduate students in an institutional Ph.D. program.

Position Requirements: Appointment of a senior, established investigator at the level of Associate Professor or Professor is preferred, although exceptional candidates for Assistant Professor will be considered. The applicant should have the Ph.D. or equivalent, such as the M.D. or D.V.M. with appropriate research experience. Preference will be given to an investigator with an established program. The appointee's interest should fall within the context of the areas cited above and be relevant to the broad discipline of environmental-toxicologic pathology or Pharmacotoxicology, including the pharmacokinetics and metabolism and mechanisms of mutagenic/carcinogenic effects of drugs and environmental chemicals.

Deadline: General inquiries or letters of application (including a curriculum vitae and a list of three references) should be sent before September 15, 1985 to: Neal C. Brown, Professor & Chairman, Department of Pharmacology. (NW154)A

**THE MACAULAY INSTITUTE
FOR SOIL RESEARCH
DEPARTMENT OF SOIL FERTILITY**

HIGHER SCIENTIFIC OFFICER

Applications are invited for appointment to a post of Higher Scientific Officer in the Department of Soil Fertility. The appointee will be required to study chemical and physiochemical factors which affect nutrient supply in the soil types prevalent in North Britain in relation to phosphate and the development of soil acidity. The successful candidate would be expected to devote part of his/her time to work on multi-disciplinary projects with crop physiologists and soil physicists within the Department, and in collaboration with other institutions.

Applicants should hold a First or Upper Second Class Honours Degree in Chemistry (with emphasis on analytical or physical chemistry), and preferably a PhD in Soil Chemistry. A minimum of 2 years' relevant post-graduate experience is required for appointment.

Salary £7,788 — £10,541 per annum, according to qualifications and experience. Non-contributory superannuation scheme operates. The Macaulay Institute for Soil Research is an Equal Opportunities Employer.

Forms of application and further particulars of the post may be obtained from The Secretary, The Macaulay Institute for Soil Research, Craigiebuckler, Aberdeen, AB9 2QJ to whom they should be returned by 9 September 1985. Quote Ref. 85/9.

SENIOR POSITIONS IN CLINICAL/ MOLECULAR GENETICS MEHARRY MEDICAL COLLEGE

Two senior positions are available in the Department of Pediatrics as follows:

- I. A chair professorship endowed by the Kellogg Foundation. We are interested in making an appointment, as soon as possible, of an individual with professional interests in Clinical/ Molecular Genetics, although exceptionally talented individuals with research interests in other areas will be considered.
- II. Under the sponsorship of the March of Dimes — Birth Defects Foundation, Meharry Medical College will appoint a distinguished scientist in the area of clinical genetics and/or molecular biology in its Department of Pediatrics. The position is sponsored under a co-operative program between the March of Dimes — Birth Defects Foundation and Meharry Medical College.

For both positions, opportunity will be created for joint appointments in appropriate basic science departments. Interested individuals should hold the M.D. degree or MD/PhD and possess professional experience appropriate for appointment at the level of Associate or Full Professor. The selected individuals are expected to have demonstrated leadership qualities necessary to catalyze institution-wide interest and expansion of research in clinical/molecular genetics and/or research related to birth defects, and to participate in regular teaching/patient care and postgraduate training programs of the Department of Pediatrics and/ or appropriate basic science department.

Nominations or applications, containing curriculum vitae, names of four individuals who may be contacted for reference, and a summary of research interests or ongoing projects, should be sent to either: Ifeanyi J. Arinze, Ph.D., Chairman, Department of Biochemistry, or Festus Adebajo, M.D., Chairman, Department of Pediatrics, Meharry Medical College, Nashville, Tennessee 37208. Meharry Medical College is an equal opportunity/affirmative action employer.

is seeking to appoint two Geneticists and a Research Worker for a period of three years in a programme of 'Alien' gene transfers in wheat, funded by the Agricultural Genetics Company.

GENETICIST (CYT/218)

to take overall charge of and considerably extend an existing programme to introduce genes for novel endosperm proteins from related species into wheat and to explore the potential of such introduced genes in improving baking quality.

Appointment will be at Higher Scientific Officer/Senior Scientific Officer.

GENETICIST (CYT/219)

to lead a programme to transfer into wheat, from its wild relatives, new genes for resistance to a range of different diseases as well as genes of potential value in hybrid wheat production.

Appointment will be at Higher Scientific Officer/Senior Scientific Officer.

RESEARCH WORKER (CYT/220)

to provide support for post CYT/219 above.

Appointment will be at Scientific Officer.

Qualifications

For posts CYT/218 and CYT/219: First or Upper Second Class Honours degree in Genetics, Biochemistry or related subjects and at least two years postgraduate for appointment at HSO and four years for appointment at SSO.

For post CYT/220, an Honours degree in Genetics, Biochemistry or related subjects with an interest in cytogenetics and plant breeding and an awareness of electrophoretic techniques.

Salary: HSO — £7,788 — & £10,541 pa

SSO — £9,772 — £12,653 pa

SO£6,190 — £8,581 pa

Further particulars available on request.

Applications with cv and names and addresses of three referees for posts CYT/218 and CYT/219 and two referees for post CYT/220, should be sent to the Establishment Officer, Plant Breeding Institute, Maris Lane, Trumpington, Cambridge CB2 2LQ by 12 September 1985, quoting relevant reference number.

The Institute is an Equal Opportunities Employer. (7461)A

**Deutsches Krebsforschungszentrum/
German Cancer Research Center Heidelberg
Institute of Toxicology and Chemotherapy
POST DOCTORAL POSITION**

Applications are invited for a three year postdoctoral position to investigate the interaction of chemical carcinogens with DNA with molecular biological techniques.

The department of Dr M Wiessler is concerned with the action of chemical carcinogens on cellular macromolecules and on regulatory processes in the cell and whole organism.

The applicant should master methods in molecular biology to enable her/him to study the expression, in appropriate vectors, of synthetic oligonucleotides containing modified bases at defined positions.

The applicant should not be older than 32 years. The position is available immediately, the salary in the range of DM 44,000 - 51,000 per annum.

Applications should be sent to: Dr M Wiessler, Institut für Toxikologie und Chemotherapie, Deutsche Krebsforschungszentrum im Neuenheimer Feld 280 0900 HEIDELBERG, Tel 06221/4841 (W2142)A

**THE DEPARTMENT OF PATHOLOGY, NEW YORK STATE
College of Veterinary Medicine**

is offering a tenure track faculty position in veterinary pathology. Responsibilities will include participation in core curriculum teaching for veterinary students, rotational assignments to diagnostic pathology services, development of independent and collaborative research programs in experimental pathology, and supervision of post DVM graduate students.

Preference will be given to candidates possessing specialty Board-certification by the American College of Veterinary Pathologists and a demonstrated research background in toxicologic pathology or chemical carcinogenesis. Academic rank and salary will be commensurate with background and experience.

Appointment will be available 1 August 1985. Candidates should submit curriculum vitae, five letters of reference, and a statement of career goals to: Robert M Lewis, DVM, Chairman, Department of Pathology, New York State College of Veterinary Medicine, Cornell University, Ithaca, New York 14853.

Cornell University is an Equal Opportunity Employer/Educator (NW156)A

SENSORY NEUROBIOLOGIST

The Department of Neurobiology and Physiology at Northwestern University is seeking applications for a faculty position, at the level of Professor or Associate Professor in the general area of Sensory Neurobiology. The successful candidate will have a strong, well established program of research, preferably in developmental or cellular/molecular neurobiology dealing with one of the sensory systems.

The Department of Neurobiology and Physiology has strong, well-funded groups in Sensory Neurobiology and in Neuroendocrinology, both representing multidisciplinary approaches to these areas of Neuroscience. The Department currently administers a PhD program; two NIH training programs are centred in the department. The Department also has an undergraduate major leading to a BA, and a BAMS honours program for exceptional undergraduates.

Interested persons should submit a curriculum vitae and the names of three persons who can provide references to:

Dr. Albert I. Farbman,
Department of Neurobiology and Physiology,
Northwestern University,
Hogan Hall, Evanston, IL 60201.

Northwestern University is an Equal Opportunity/Affirmative Action Employer. (NW167)A

**UNIVERSITY OF LA
LAGUNA
CANARY ISLANDS**

**Announces a vacancy as
VISITING PROFESSOR IN
ASTROPHYSICS**

Applications are invited for a 1 year position as a visiting professor at the Departamento de Física de la Tierra y del Cosmos, with possible extension for a longer period.

This position involves teaching astrophysics to Undergraduates in physics (speciality of Astrophysics) and leading research groups with postgraduates. The candidates should have broad research experience and have directed groups in astrophysics. Research will be carried out at the Institut de Astrofísica de Canarias to which depend the International Observatories of "Teide" (Tenerife) and "Rogue de los Muchachos" (La Palma). Knowledge of the spanish language at an elementary conversational level is required. A higher level would be favourably considered. The salary will be 2.419.960 pesetas.

Applications must be accompanied by curriculum vitae and a list of publications. These must be submitted to EXCMO RECTOR University of La Laguna, La Laguna, Tenerife, before the 20th of October, 1985 (W2139)A

**ST GEORGE'S HOSPITAL
MEDICAL SCHOOL
(University of London)
TECHNICIAN 3**

required to join the established staff of the Electron Microscopy suite. The suite consists of transmission and scanning EM and freeze-fracture equipment and provides a service for pre-clinical departments.

Training will be given in EM techniques. Scale £5,399 — £6,325 pa plus London Allowance £730 pa. Further details and an application form available from the Personnel Officer, St George's Hospital Medical School, Cranmer Terrace, Tooting, London SW17 0RE (tel 01-672-1255 ext 4873). Closing date for applications 12 September 1985. Quote reference 13/85 (7473)A

**POSTDOCTORAL
POSITION
YEAST MOLECULAR
GENETICS**

available immediately to study the dsRNA viruses of *S. cerevisiae* with emphasis on the chromosomal genes which affect viral replication and gene expression. Attractive compensation package. Potential for academic appointment with the opportunity to develop an independent research program in 2-3 years. Please submit curriculum vitae and names of three references to Steve S. Sommer, MD, PhD, Department of Cell Biology, Mayo Foundation School of Medicine, Rochester, MN 55905.

An equal opportunity/affirmative action institution (NW163)A

**UNIVERSITY OF
CAMBRIDGE
Department of Pathology
POST-DOCTORAL
MOLECULAR BIOLOGIS**

Applications are invited for a postdoctoral position, tenable for 1 years from 1st October 1985, in a small group investigating immunology and molecular biology of schistosomiasis.

Candidates are sought with experience in molecular biology who would be primarily concerned with the preparation and detection of cDNA clones encoding and expressing antigens associated with the development of protective immunity but would also be free to follow other areas of current interest in molecular biology of schistosomiasis. Previous post-doctoral experience would be desirable, but is by no means essential.

Salary on postdoctoral scale dependent on age (£7,520 age 24 £9,390 age 28, under review).

Informal enquiries welcomed to A E Butterworth or Dr D W Taylor (Department of Pathology, Tennis Court Road, Cambridge CB2 1Q Telephone 0223-64631).

Formal applications, including curriculum vitae and the names of two referees, to Mr P Wilburn, Superintendent, Tennis Court Road Cambridge CB2 1QP (7463)A

**UNIVERSITY OF ILLINOIS
College of Dentistry
DEPARTMENT OF
ORAL ANATOMY
HEAD**

Individual of scientific attainment sought to head a department with research emphasis in function, morphology and teaching duties in gross, neuro and dental anatomy. Both DDS and PhD are desirable. Position available July 1, 1986.

Send curriculum vitae, publications and names of five references to Dr Dale R Eisenmann, Chairman of Search Committee, Department of Histology, University of Illinois at Chicago, PO Box 6998, Chicago, Illinois 60680. The University of Illinois is an Affirmative Action Equal Opportunity Employer. (NW170)A

**PRINCETON UNIVERSITY
GEOCHEMIST**

to participate in the development of models of trace metal cycling processes for incorporation in three dimensional ocean circulation and biological cycling models presently in development. Participation in measurement programs a possibility. Appointment will be to the Research Staff at the postdoctoral level or higher. Send résumé and 3 references to the Director, Geophysics Fluid Dynamics Program, Department of Geological and Geophysical Sciences, Princeton University, Princeton, NJ 08544. Princeton University is an equal opportunity affirmative action employer. (NW169)A

THE UNIVERSITY OF PAPUA NEW GUINEA

Port Moresby

SENIOR LECTURER/
SOCIATE PROFESSOR IN

DEPARTMENT OF FISHERIES

Applications are invited for the above position in the Department of Fisheries. The post falls vacant at the end of 1985. Applicants should have a B.Sc. in Fisheries or a related discipline. Preference will be given to candidates with both teaching and research experience in the discipline. The appointee shall be responsible for academic leadership in the Department of aquatic resources management in the Department, and should have proven expertise in the following areas: Fisheries Management, Economics/Fisheries Economics, Aquatic Resources Management. Experience in Fish Population Dynamics and Quantitative Methods in Fisheries could be an advantage.

Salary: Associate Professor K23,500 per annum plus gratuity; Senior Lecturer K21,255 per annum plus gratuity; Lecturer Grade 2 K19,405 per annum plus gratuity; Lecturer Grade 1 K17,555 per annum plus gratuity.

Conditions of Appointment The successful applicant will be normally offered a contract for a three year appointment ending at the end of a calendar year. The gratuity entitlement is based on 24% of salary earned and is payable in instalments or lump sum. It is taxed at a flat rate of 2%. In addition to the salaries quoted above, the main benefits include support for approved research; rent; accommodation; appointment of repatriation airfares for appointee and dependents; financial assistance towards the cost of transporting personal effects to and from PNG; 6 weeks annual recreation leave with home airfares available after each 18 months of continuous service; generous education subsidies for children attending schools in PNG or overseas; a salary continuation scheme for extended illness or disability. Applicants wishing to arrange secondment from their home institutions will be welcomed. The terms and conditions are under review.

Applications will be treated as strictly confidential and should include a full curriculum vitae, a recent passport photograph and the names and addresses of three referees. Applications should be forwarded to the Deputy Registrar (Staffing), University of Papua New Guinea, PO Box 90, University Post Office, Papua New Guinea, to reach him as soon as possible. Candidates in the UK could also send a copy of their applications to the Secretary General, Association of Commonwealth Universities (Appsts), 36 Gordon Square, London WC1H 0PF. (W2143)A

NATURE CONSERVANCY COUNCIL

MARINE/COASTAL
ECOLOGIST

Higher Scientific Officer
13 month contract post

Applications are invited for the above contract post with the Chief Scientist Directorate, to be based in the Nature Conservancy Councils Great Britain Headquarters in Peterborough.

The post is jointly funded by British Petroleum and the NCC and will be for 13 months in the first instance but possibly extending to three years. The project will involve the planning, promotion, co-ordination and analysis of surveys of coastal and intertidal habitats by voluntary bodies, educational and amateur groups. The person appointed will be expected to travel widely throughout Great Britain and should have some experience in data handling.

Qualifications: Applicants should have a degree in biology, geography or a related subject and have at least 2 years relevant post graduate experience. A current driving licence is essential.

Salary: depending on qualifications and experience £7,788 rising to £10,541.

For an application form and further details of the post, please contact Miss B.A. Meredith, Personnel Officer, Nature Conservancy Council, Northminster House, Peterborough, PE1 1UA, to whom completed forms should be returned by 12th September 1985.

The Nature Conservancy Council is an equal opportunity employer. (7450)A

Cell Physiologist (PhD)

elf bic
recherches

Elf Bio Recherches, a subsidiary of Elf Aquitaine and Sanofi, specialises in biotechnology. It is looking for a Cell Physiologist for its laboratory of animal cell physiology and fermentation. This laboratory (2 scientists and 3 technicians) forms part of the recombinant animal cell technology unit. The research activities of this group include the investigation of the role of physiological factors involved in the expression of genes cloned into animal cells. Candidates should have a profound knowledge of animal cell physiology. Experience in medium or large-scale tissue culture will be an advantage. Knowledge of French would be appreciated. Elf Bio Recherches R & D facilities are located in the Toulouse area, in Southern France. Curriculum vitae and list of publications should be sent to Mr Fabre quoting **Reference B/T 2018N**. (W2149)A

PA

71 bis, allées Jean-Jaurès, 31000 Toulouse, France.
Tel: Toulouse 63.70.63.

ELSEVIER PUBLICATIONS (Cambridge)

We are looking for an

EDITOR

for a monthly review journal in the biological sciences. The ideal candidate will have:

- Research experience in *either* some area of ecology or evolutionary biology. Applicants must be able to demonstrate a broad knowledge of current issues in population biology (This will be a new appointment), *or* some area of neuroscience. Applicants must be able to demonstrate a broad interest in clinical, systems and molecular neurobiology.
- Experience and ability in scientific editing or writing.
- Enthusiasm for explaining the latest advances in a rapidly changing field to an audience with a wide diversity of experience.
- Organisation skills, an eye for detail and the ability to work to deadlines.
- The position will ideally suit someone with post-graduate research experience, aged 30, or less.

The new journal will be published alongside our current successful line of monthly review journals in biomedicine, including *Trends in NeuroSciences* and *Trends in Biochemical Sciences*. The position is situated in our pleasant modern offices in Cambridge. The salary will be based in age and experience.

Please send your c.v. and relevant details to:

Dr J.D. Bousfield,
Elsevier Publications (Cambridge),
68 Hills Road, CAMBRIDGE CB2 1LA (7487)A

Harvard University
ASSISTANT PROFESSOR
CELLULAR AND DEVELOPMENTAL
BIOLOGY (CDB)

The Department of Cellular and Developmental Biology intends to make one and possibly more appointments at the assistant professor level effective July 1, 1986. Our department covers a broad range of topics in cellular biology and developmental/ molecular genetics. We are seeking outstanding candidates in these fields. We are particularly interested in possible appointments in the areas of vertebrate development, neurobiology, plant molecular biology, and cell biology. However, we will consider exceptional applicants in other fields as well. We encourage applications from women and minority groups. Applications should include curriculum vitae, reprints of publications, and a statement of research plans. Complete applications and three letters of recommendation, solicited by the applicant, should be received no later than October 31, 1985 by:

Diane Baldwin, Administrator
 CDB Search Committee
 Cellular and Developmental Biology
 The Biological Laboratories
 Harvard University
 16 Divinity Avenue
 Cambridge, MA 02138

Harvard University is an Affirmative Action/Equal Opportunity Employer (NW102)A

CELL BIOLOGY
AND PHYSIOLOGY
WASHINGTON UNIVERSITY SCHOOL
OF MEDICINE
ST LOUIS, MISSOURI

The Department of Cell Biology and Physiology, Washington University School of Medicine, St Louis, Missouri, is expanding its commitment to research in the following areas: (i) membrane protein function and biogenesis; (ii) assembly, function, and movement of intracellular organelles; (iii) cell motility and contractility; and (iv) cell-cell and cell-matrix interactions. Individuals who employ novel biophysical and recombinant DNA methodologies are especially encouraged to apply. Tenure track positions are available for successful candidates who will be expected to develop an independent research program and to participate in the training of medical and graduate students.

Please submit curriculum vitae and the names of three references to: Dr Philip Stahl, Department of Cell Biology and Physiology, Washington University School of Medicine, 660 South Euclid Avenue, St Louis, MO 63110.

An Affirmative Action / Equal Opportunity Employer.
 (NW158)A

ASSISTANT PROFESSOR
OF MICROBIOLOGY

The Department of Microbiology, University of Illinois, Urbana, invites applications for a full-time (9 months/year) tenure-track appointment at the assistant professor level. The position is available for August of 1986. Applications must have a Ph.D. and at least two years of postdoctoral experience. Preference will be given to applicants who have demonstrated research competence in molecular biology and who plan to work in the general area of microbial genetics and physiology. The appointee is expected to establish a vigorous research program, to participate in undergraduate and graduate teaching, and to supervise graduate students. Salary will be commensurate with education and experience.

Applicants should send curriculum vitae, a summary of future research interests, and the names and addresses of three references to: Dr. A. Salyers, Department of Microbiology, University of Illinois, 131 Burrill Hall, 407 S. Goodwin, Urbana, Illinois 61801 (217-333-7378). To receive full consideration applications should be received by November 15, 1985. Some interviews may be conducted before November 15, 1985. However, all applications that are received by that date will be given equal consideration. (The University of Illinois is an Equal Opportunity/Affirmative Action Employer).
 (NW134)A

GEOLOGICAL
ENGINEERING/
ENGINEERING
GEOPHYSICS

Tenure Track

Applications are invited from suitable qualified geologists and engineers to teach geological engineering classes at both the graduate and undergraduate level and to pursue research interests in either experimental or computational rock mechanics.

Applicants should be qualified at the Ph.D. Level and ideally should be eligible for registration as Professional Engineers. Appointment is likely to be made at the rank of assistant professor.

Letters of application naming three referees should be addressed to Professor M.J. Reeves, Search Committee Chairman, Department of Geological Sciences, University of Saskatchewan, Saskatoon, Sask., S7N 0W0, Canada. (NW162)A

UNIVERSITY OF LONDON
Institute of Neurology
POSTDOCTORAL
RESEARCH ASSISTANT

A postdoctoral research Assistant with research experience in psychopharmacology and related fields is required for an MRC-supported project on the behavioural functions of GABA — and benzodiazepine-sensitive brain pathways in rats. The present project will have another two years to run, from a date on or after October 1st 1985. Salary and superannuation on University scales.

Apply with CV and names of referees to Dr L J Herberg, Experimental Psychology Laboratory, Institute of Neurology, the National Hospital, Queen Square, London WC1N 3BG.

(7448)A

LABORATORY OF
MOLECULAR BIOLOGY

Genzentrum Munich/
 Martinsried

POST DOCTORAL
SCIENTIST

Student (holding a masters degree, aim: Dr rer, nat)
TECHNICIAN

Applicants should have experience or strong interest in: Molecular Biology, Gene cloning — sequencing, Immunology, Biochemistry. The successful candidate(s) will join a young team and enjoy to do science on the following subjects: Molecular characterisation of the transformed cell, control of proliferation in the normal and transformed cell, virus-cell interaction, cell differentiation.

The positions are available but may be delayed for suitable candidates. Please write enclosing CV and names of two referees to: Dr K H Westphal, Lab f, Mol, Biol, Genz, MPI/Biochemie, Am Klopferspitz, 8033 Martinsried, FRG
 (W2147)A

UNIVERSITY OF LONDON
CHAIR OF VETERINARY
MOLECULAR AND
CELLULAR BIOLOGY

at the Royal Veterinary College

The Senate invite applications for the above Chair which is newly established. Candidates should possess a veterinary, medical or biological science degree and a PhD or similar higher degree. A good knowledge of the techniques of biotechnology, proven research record relevant to veterinary science and experience in teaching are required. The person appointed will head an inter-departmental project team which will bring together a group from various departments of the College to use techniques of biotechnology which are vital to the development of veterinary science and medicine. This would be the only such inter-departmental group in a veterinary school and only such Chair in UK.

Salary within the Professor's range. The current minimum £19,303 including London Allowance.

Removal expenses may be reimbursed up to £1,400.

Intending applicants should obtain further particulars from the Academic Registrar (N), University of London, Malet Street, London WC1E 7HU before submitting applications (10 copies).

The closing date for receipt of applications is 20 September 1985. Potential candidates are invited to contact the Principal of the Royal Veterinary College. (7466)A

ROYAL PERTH HOSPITAL
Western Australia
GENETICIST/COMPUTER
PROGRAMMER/
BIOMEDICAL
STATISTICIAN

Applications are invited for a position suitable for a Post Doctoral Fellow, funded by the Western Australia Arthritis and Rheumatism Foundation and administered by the University of Western Australia. Duties will include maintenance and development of computer programmes used in genetic analysis including DNA sequencing. The applicant will join a group involved in N + MRC funded research on immunogenetics and will be expected to provide advice on statistics and maintain patient and population data bases relevant to arthritis and immunogenetics.

The appointment will initially be for one year with a probability of renewal. With relevant qualifications salary will commence at \$26,236 PA.

Enquiries and applications should be directed to: Dr R L Dawkins, Department of Clinical Immunology, Royal Perth Hospital, Wellington Street, Perth, Western Australia 6000.

Closing date September 20, 1985.
 (W2146)A

DERBYSHIRE COLLEGE
OF HIGHER EDUCATION

Research Assistant in Fern Ecology

(3 Years)

Applications are invited by 13th September 1985 from graduates with a good honours degree to study the establishment of ferns in woods near Derby. The successful applicant will be expected to register for a higher degree.

Salary: £5,181 to £6,405 per annum subject to revision

Application forms and further details from the Staffing Officer, Derbyshire College of Higher Education, Kedleston Road, Derby DE3 1GB.

(7472)A

POST VACANCY FOR A SCIENTIFIC PROGRAMMER IN ADDIS ABABA VACANCY INT/002/85

The International Livestock Centre for Africa, ILCA, has a vacancy for a Scientific Programmer at its headquarters in Addis Ababa. The successful candidate will have a basic animal science degree or equivalent, post graduate qualifications with at least five years of experience in computer science and proven qualities in undertaking all aspects of extraction, analysis and interpretation of major data sets in animal production and related fields. The main language is Fortran. Hardware involved are 2 HP3000 mini-computers and a network of micros. Experience with micros is also desirable, and an ability to liaise with a wide range of research workers essential.

This is an international staff position and the salary will be paid in US dollars. The initial contract will be two years renewable annually thereafter, subject to satisfactory performance and financial resources being available. Initial salary level will be determined by qualifications and experience. Moving and education allowances are paid and there are medical and retirement benefits.

Applications should include a current curriculum vitae and the names and addresses of three referees. Applications citing the reference number should be sent by 30th September 1985 to the Personnel Officer, International Livestock Centre for Africa, P.O. Box 5689, Addis Ababa, Ethiopia.

(W2150)A

UNIVERSITY OF CAMBRIDGE

Post-graduate/post-doctoral RESEARCH ASSISTANT NEUROENDOCRINOLOGIST

To join multi-disciplinary neuro-endocrine research group in MRC supported project to investigate the neural basis of photorefractoriness in seasonal breeding. Background in endocrinology/neuroscience preferable.

Post available autumn 1985 for three years. 1A salary scale.

Applications and further details: Mrs J Penton, Dept. of Anatomy, University of Cambridge, Downing Site, Camb CB2 3DY. Please arrange for 2 referee's reports to accompany application. (7454)A

ROYAL PERTH HOSPITAL Western Australia POST DOCTORAL FELLOW

At least one Post Doctoral Fellow is required to develop an aspect of several NH + MRC projects investigating the immunogenetics of autoimmune disease, utilising recombinant DNA technology. Some experience in molecular biology and immunogenetics is desirable. The appointment will be for one to three years. Salary will be based on NH + MRC scales commencing at A\$22,614 but with supplements as appropriate.

Enquiries and applications should be directed to: Dr R L Dawkins, Department of Clinical Immunology, Royal Perth Hospital, GPO Box X2213, Perth Western Australia 6001

Closing date September 20 1985
(W2145)A

JOHN INNES INSTITUTE SCIENTIFIC OFFICER

Applications are invited for a Scientific Officer to assist in a research programme aimed at the regeneration of crop plants from tissue cultures. This is a funded post and the appointment will be for approximately 18 months.

Applicants should have an honours degree in a biological science or HNC with relevant post-qualifying experience.

The appointment will be to the Scientific Officer grade, with salary on the scale £6,190 to £8,561. Non-contributory superannuation.

Applications, quoting reference AG/202, together with a full cv and the names of two referees should be sent to the Secretary, John Innes Institute, Colney Lane, Norwich, NR4 7UH. (7451)A

CAMBRIDGE MRC Laboratory of Molecular Biology POST-DOCTORAL SCIENTISTS

Applications are invited for post-doctoral positions of about 2 years' duration in microbial or molecular genetics. Experience in recombinant DNA techniques would be advantageous but training can be provided.

Salary in the range £8,920 — £14,925 pa. Starting date flexible but autumn 1985 preferred

Applications — including a full CV, a short statement of research experience and the names of two professional referees — should be sent by 12th September 1985 quoting reference MG/85 to the Assistant Director, MRC Laboratory of Molecular Biology, Hills Road, Cambridge CB2 2QH (7441)A

POSTDOCTORAL RESEARCH AND TRAINING OPPORTUNITIES

are available at the

CHEMICAL INDUSTRY INSTITUTE OF TOXICOLOGY

The Chemical Industry Institute of Toxicology (CIIT) offers a two-year post-doctoral research training program in toxicology for individuals who have recently earned a D V M M D. or Ph.D. in an academic discipline related to toxicology. Research programs stress elucidation of basic mechanisms of toxicity and often employ a multidisciplinary approach. Areas of interest include mutation and chemical carcinogenesis, pharmacokinetics and metabolism, teratogenicity, development of *in vitro* tests for toxicity, immunotoxicity, reproductive system toxicity, inhalation toxicology, epidemiology and quantitative risk assessment.

For more information contact: Coordinator of Training, Chemical Industry Institute of Toxicology, P.O. Box 12137, Research Triangle Park, NC 27709. (NW166)A

MARIE CURIE MEMORIAL FOUNDATION RESEARCH INSTITUTE POST DOCTORAL RESEARCH POSITIONS

to study the role of the cellular p53 oncogene in multi-stage carcinogenesis.

1. The role of p53 in SV40 and Adenovirus transformation. Reagents available include p53 deletion mutants that bind SV40T or Elb55k but are defective for cellular immortalization, point mutants that fail to bind the viral oncogene products and p53 antisense retroviral vectors.
2. Investigation of p53 mutants that exhibit enhanced activity in cellular immortalization assays.

These three year positions are funded on the University Lecturer scale.

Applications, C.V. and the names of two referees to Dr. J. Jenkins, MCMF Research Institute, The Chart, Oxted Surrey (088-388-2306). (7445)A

CONNAH'S QUAY, DEESIDE, CLWYD
RESEARCH DIVISION
POSTDOCTORAL RESEARCH
ASSISTANT BIOTECHNOLOGY
 (INITIALLY FOR ONE YEAR)

A Research Assistant is required to work on a joint SERC/industrial programme on the development of immunoassays for food analysis. Applicants should have a good honours degree and Ph.D., with experience of antibody preparation and immunoassays, especially ELISA. The appointment, initially for 12 months, will be on the Researcher B1 Scale (£7,548 — £10,251 pa).

Further details and application form from The Registrar, The North East Wales Institute, Connaah's Quay, Deeside, Clwyd. Tel: Deeside 817531 Extn. 254. Closing date for receipt of applications 7th September 1985. (7488)A

UNIVERSITY OF DUNDEE
DEPARTMENT OF BIOCHEMISTRY
POST-DOCTORAL
RESEARCH ASSISTANT

Applications are invited for the above SERC-funded position which forms part of a small group studying the mechanism of cofactor acquisition by molybdoenzymes in *E. coli*. The project involves the biochemical analysis of a series of mutants which are defective in molybdoenzyme biosynthesis. Enzymological and molecular genetic approaches are being employed. Persons with experience in either or both of these areas are preferred but other strong applicants will also be considered. Further information may be obtained from Dr D H Boxer (0382 23181, ext 4250). The position is available for up to three years starting as soon as possible.

Appointment will be on the Research & Analogous 1A scale currently £7,520 — £12,150 (under review) depending on qualifications and experience.

Please apply enclosing a curriculum vitae and the names of two referees to The Personnel Officer, The University, Dundee, DD1 4HN as soon as possible. Please quote Ref EST/75/85J. (7453)A

UNIVERSITY OF BATH
School of Biological Sciences

LECTURER IN
VEGETABLE CROP
PRODUCTION

(Three year contract with the possibility of renewal)

Applications are invited from plant physiologists with experience of field and/or protected vegetable crop production, including field experimentation. The successful candidate will be expected to develop a research programme which interacts with existing interests in one or other of the following areas: stress physiology, seed physiology, micropropagation, growth regulators.

The teaching duties will be concerned with the BSc Course in Horticulture and the MSc Course in Crop Production (Horticulture).

Salary within the range £7,520 — £14,925.

Further particulars and application forms may be obtained from the Personnel Officer, University of Bath, Bath BA2 7AY, quoting reference number 85/127.

Closing date for applications: 12th September 1985. (7443)A

*** * * SENIOR SCIENTIST * * ***

The W. Alton Jones Cell Science Center, Inc., Lake Placid, New York has an immediate opportunity for a young, innovative and experienced molecular biologist to direct independent research in the field of molecular and cellular biology.

We are seeking a dedicated and talented scientific professional with interest in cell biology and growth factors. The successful candidate will have a doctorate in molecular and cellular biology with at least 3 years postdoctoral experience. Candidates must have the ability to supervise others. Liberal benefits. Salary will commensurate with experience.

Applicants are requested to submit complete curriculum vitae and to have three letters of academic references forwarded by October 1, 1985 to:

Personnel Manager

PRESSURE

Applicants are invited for the post of Research Associate to work with Dr R G Ross in the School of Mathematics and Physics on the measurement of thermal conductivity and heat capacity of solids and liquids at high pressures and temperatures, using the transient hot-wire method. The post is tenable for three years from October 1985 and has a starting salary of up to £7,980 per annum on the RA (1B) scale (under review). Applicants should have a good honours degree in physics or a related subject, and may register for a higher degree.

A curriculum vitae and the names of two referees should be sent to the Senior Administrative Assistant, School of Mathematics and Physics, University of East Anglia, Norwich NR4 7TJ. (7478)A

UNIVERSITY OF
CAMBRIDGE

University Chemical
 Laboratory

POSTDOCTORAL
RESEARCH ASSISTANT

Applications are invited for two posts of Postdoctoral Research Assistant to work with Dr D Williams on the structure elucidation of antibiotics and peptides. Previous experience with HPLC, proton nuclear magnetic resonance and/or FAB mass spectrometry will be a advantage. Appointments will be made for one year in the first instance, and will commence in the period 1 October 1985 to January 3 1986. Initial salary will be either £7,520 or £7,980 per annum.

Applications, which should include a curriculum vitae together with the names of two referees should be sent to Dr D H Williams University Chemical Laboratory Lensfield Road, Cambridge, CB2 1EW. (7457)A

UNIVERSITY OF
LIVERPOOL
DEPARTMENT OF GEOLOGY
TECHNICIAN GRADE 3

Required in the recently established Sedimentology Laboratory. The successful applicant will be responsible for operating a range of sedimentological research techniques, assisting in the training of students in these techniques and maintaining the laboratory. Experience of grain-size analysis, heavy mineral separation, cathodoluminescence microscopy, impregnation and staining techniques as applied to sediments and sedimentary rocks would be an advantage.

Candidates must possess O.N.C. plus three years experience as a minimum qualification but applications from graduates in Earth Sciences will also be welcomed.

Salary within the range £5,399 — £6,325 pa (under review).

Application forms may be obtained from the Registrar, The University, PO Box 147, Liverpool, L69 3BX.

Ref: PER/754/N (7444)A

MEDICAL RESEARCH
COUNCIL
National Institute for
Medical Research
DIVISION OF
IMMUNOLOGY

Applications are invited for a post-doctoral position in the Division of Immunology to work with Dr B Askonas. The appointment will be for three years, starting in late autumn, to work on aspects of T-cell function and recognition in respiratory virus infection (particularly influenza) in a mouse model. Experience in cellular immunology, tissue culture or virology would be an advantage.

The salary will be in the range of £8,920 — £10,720 per annum, plus £1,233 London allowance and superannuation provision.

Applications, together with curriculum vitae, research experience and interests in the names of two professional referees, should be sent to the Assistant Director, National Institute for Medical Research, The Ridgeway, Mill Hill, London NW7 1AA by 13 September 1985, quoting ref IMM/1. (7452)A

POSTDOCTORAL FELLOW

Human Immunogenetics

Immediately available two-year position working in areas of histocompatibility, transplantation and regulation of human T-cell responses to influenza virus, including: graft vs host disease, T-cell clone biology, immunochemistry of T-cell surface molecules, structure and function of human alloantigens.

Send vitae to: David D. Eckels, PhD, Blood Center Southeastern Wisconsin, 1701 West Wisconsin Avenue, Milwaukee, Wisconsin 53233. (NW173)A

NORTH EAST BIOTECHNOLOGY CENTRE

Applications are invited for the following post which will be based at:

TEESSIDE POLYTECHNIC in the DEPARTMENT OF CHEMICAL ENGINEERING PRINCIPAL LECTURER IN BIOCHEMICAL ENGINEERING

To take responsibility for the operation and further development of the Biochemical Engineering content of courses in process engineering run jointly by the Department of Chemical Engineering and the North East Biotechnology Centre.

It is expected that the successful candidate will also undertake research projects, especially in aspects of downstream process design.

Applicants should be well qualified in Biochemical Engineering or a discipline of fundamental importance to this subject area. They should have demonstrated a proven research record in a relevant area, an effective approach to student teaching and appropriate experience. Members of an appropriate professional institution would be an advantage.

Salary: £13,095 — £14,580 (work bar) — £16,467 per annum.

The salary on appointment will be no greater than £14,580 per annum.

Application forms and Further Particulars from Personnel Section, Teesside Polytechnic, Borough Road, Middlesbrough, Cleveland, TS1 3BA, Telephone (0642) 218121 Ext. 4114.

Closing date for applications: 16 September 1985.

An Equal Opportunity Employer (7446)A

UNIVERSITY OF ST ANDREWS

Department of Anatomy
and Experimental Pathology

Applications are invited for a

POSTGRADUATE RESEARCH ASSISTANT 1B

to work with Dr P. E. Bryant on a project, funded by the Cancer Research Campaign, to investigate mechanisms of, and factors affecting the induction of chromosomal aberrations in mammalian cells. The person appointed will use recently developed techniques in which the DNA of living cells is cut with restriction endonucleases. DNA and chromosomal damage arising from this treatment as well as from exposure to X-rays will be investigated using a variety of biochemical and cytogenetical methods.

The post is for 3 years, starting in October, 1985. Starting salary within range £6,600 — £7,055 on 1B scale. Experience with cytogenetical and tissue culture techniques would be an advantage. Further details may be obtained from Dr P. E. Bryant.

Applications, with the names of two referees, should be sent to the Establishments Officer, The University, College Gate, St Andrews, Fife KY16 9AJ by 16th September, 1985 (7404)A

UNIVERSITY OF BRISTOL

Department of Biochemistry

COMPUTER MANAGER

(other related 1A)

Applications are invited for the post of Computer Manager. The duties of the Computer Manager will be to assume responsibility for the operation of molecular graphics equipment and for computing facilities within the Department of Biochemistry. It is also expected that the Computer Manager will take part in research on protein structure and function. Current structurally related research projects in the Department concern glycolytic enzymes, transferrin and site directed mutagenesis.

The appointment is jointly funded by the SERC and the University of Bristol and initially will be for a period of 3 years. Starting salary will be up to £8,450 pa.

Further particulars may be obtained from Dr J. J. Holbrook, Dr H. Muirhead or Dr H. C. Watson, Department of Biochemistry, University of Bristol, BS8 1TD. Applications (3 copies) should include curriculum vitae and names and addresses of 2 referees (7456)A

MICROBIOLOGIST

Plant Protection Division's world research centre is at Jealott's Hill, where we are seeking to strengthen one of our research teams in Agricultural Microbiology by the addition of an innovative research scientist. In particular the new areas of interest will be in developing model systems for the analysis of the Mode-of-Action of pesticides, and isolating bacteria capable of degrading pesticides or resistant to pesticides. There are lots of opportunities for initiative in this exciting area of research. We are looking for a graduate with a first class honours degree or 2(i) in Microbiology and with an M.Sc or experience in biochemistry.

Jealott's Hill Research Station is pleasantly situated between Bracknell and Maidenhead. We offer competitive salaries and other benefits include profit sharing and pension. There is a staff restaurant, recreation club and shop on site.

Please apply with full details of your age, qualifications and experience to: Personnel Department, ICI Plant Protection Division, Jealott's Hill Research Station, Bracknell, Berkshire RG12 6EY. Please quote reference: Microbiol/KAP.

The closing date for this vacancy is 6 September 1985

Plant Protection
Division

(7482)A

RESEARCH ASSISTANT PROFESSOR (non-tenured track)

to study bacterial chemotaxis as part of a research group. Background in molecular genetics or protein structure/chemistry preferred. Five-year position involves light teaching load.

Salary \$24,000 to \$28,000, depending on qualifications. Must have Ph.D and postdoctoral training.

Send curriculum vitae and three reference letters to: Dr. G.L. Hazelbauer, Biochemistry/Biophysics, Washington State University, Pullman, WA., 99164-4660.

Washington State University is an Equal Opportunity/Affirmative Action Employer. (NW164)A

AGROGEN BIOTECHNOLOGIES INC. RESEARCH SCIENTIST — PROJECT LEADER ECOPHYSIOLOGY/ MYCORRHIZAE

Agrogen Biotechnologies Inc. a Vancouver based Canadian company interested in plant tissue culture, micropropagation of woody ornamentals and forest tree species and related biotechnologies is seeking a Research Scientist to act as Leader of its research project on ecophysiology of mycorrhizae symbiosis.

The position requires a Ph.D. in Forestry with specialization in ecophysiology and ectomycorrhizae, post-doctoral experience in water relations and ecophysiological evaluation of plant growth responses, demonstration of supervisory skills through the conduct of complex research projects and demonstration of independent scholarly research through publication in recognized scientific journals.

Agrogen offers the opportunity to join an energetic interdisciplinary research team, excellent research facilities competitive salary and fringe benefits.

Please forward your curriculum vitae and other pertinent information including the name of 3 references by September 30, 1985, to: Dr. D. Paul Webb, Director of Research, Agrogen Biotechnologies Inc., 1710 — 1066 West Hastings St., Vancouver, B.C., V6E 3X2, Telephone (604) 683-0345. (NW172)A

Experimental Scientist (X-Ray Diffraction) Synchrotron Radiation Research

The Daresbury Laboratory, one of the Science and Engineering Research Council's major laboratories, situated in the North Cheshire countryside, is developing large scale national facilities for research into atomic, molecular and biological sciences, nuclear physics and computational science. In particular, the Synchrotron Radiation Source (SRS) supplies X-radiation, UV and IR to over 20 experimental stations where new and exciting research programmes are being carried out.

We have a vacancy in the Synchrotron Radiation Division for a person who would be developing facilities for powder diffraction and single crystal work, including surface diffraction. A two-circle instrument is already installed in the intense X-ray beam from the SRS wiggler magnet and a four-circle instrument is being purchased. We need a person with a strong background in physics, chemistry or materials science with practical experience in the application of diffraction techniques. The person appointed will assist a wide range of instrument users in the development of their research programmes and play a leading role in the application of the two-circle and four-circle instruments to new scientific problems. Dedication, enthusiasm and a willingness to form part of a team of hard working scientists are all essential pre-requisites for this post.

Depending on qualifications and experience the appointment will be made in the grade of Scientific Officer or Higher Scientific Officer on a salary scale of £6,190 to £8,561 or £7,788 to £10,541 per annum. There is a non-contributory superannuation scheme, a generous leave allowance and a flexible working hours scheme. Applicants should have a degree or equivalent in a relevant subject.

For further information please contact the Personnel Officer, from whom application forms may be obtained and should be returned quoting reference number DL/927 to:

The Personnel Officer, Daresbury Laboratory,
Science and Engineering Research Council,
Daresbury, Warrington,
Cheshire WA4 4AD.

SCIENCE & ENGINEERING
RESEARCH COUNCIL

LA TROBE UNIVERSITY Melbourne, Australia

School of Biological Sciences RESEARCH ASSOCIATE IN BIOCHEMISTRY

A Research Associate is required to work on cyclic AMP metabolism and Ca^{2+} mediated processes (including protein phosphorylation) in plants. The appointee will be a member of a research group headed by Dr Gideon Polya in the Department of Biochemistry. It is expected that the successful applicant will commence in 1985. The position is funded by the Australian Research Grants Scheme for a period of 2 years. Applicants must have a PhD in biochemistry or a closely related field. Further details of the position may be obtained from Dr Polya by writing or telephoning (03) 478 3122 Ext 2157. Applicants should ask two referees to send their confidential reports to the Staff Officer, La Trobe University, by the closing date, or as soon as possible thereafter.

Salary: \$A22,614 — \$A23,934.

Applications marked 'Confidential' and quoting AO/004/002, close with the Staff Officer, La Trobe University, Bundoora, Victoria, Australia 3083, on 16 September 1985. Candidates in UK should also send a copy of their applications to the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, from whom further general information is available.
(W2148)A

MEDICAL RESEARCH COUNCIL CLINICAL & POPULATION CYTOGENETICS UNIT BIOLOGIST

Applications are invited for a Short-Term Non-Clinical Scientific post in the above Unit, tenable for 3 years from October 1985. Candidates of immediately post-doctoral or equivalent status, and having some experience in cytogenetics or relevant molecular biology will be preferred. The appointee will work with a group using DNA probes in studies on chromosome anomalies in normal and malignant human cells.

Remuneration will be at an appropriate point on the scales for University non-Clinical academic staff. Further details from, and applications, with names and addresses of two referees, to the Administrator, MRC Clinical and Population Cytogenetics Unit, Western General Hospital, Crewe Road, Edinburgh EH4 2XU, by September 9th, 1985, quoting reference HJ/8/2989

UNIVERSITY OF LONDON Imperial College of Science and Technology POSTDOCTORAL RESEARCH ASSISTANT

required for a 2 year appointment to do in-line measurement and computer analysis of electro-cardiographic signals and their interpretation in relation to a computer model of the human thorax, in collaboration with St Mary's Hospital.

The successful candidate will be expected to have a postgraduate degree in Electrical Engineering and Computer Science, a knowledge of real-time programming and experience in physiological measurement in a clinical environment. Salary will be on a scale £8,753 — £13,383 (under review).

Applications to Dr D M Monro, Department of Computing, Imperial College, SW7 2AZ by 12 September 1985
(7486)A

UNIVERSITY OF LONDON Institute of Obstetrics and Gynaecology — Hammersmith Hospital, Ducane Road, London W12 0HS POST DOCTORAL RESEARCH ASSISTANT

required to study the hormonal regulation of protein synthesis in human endometrial carcinoma. The project will involve tissue culture and analysis by PAGE of cellular and secreted proteins labelled in-vitro. Previous experience of these techniques is desirable but not essential. The position is available for 3 years and is funded by a project grant from the Cancer Research Campaign. Salary up to £11,205 inc of LW.

Applications in the form of a CV including the names of 2 academic referees should be sent to Dr J O White at the above address. Informal enquiries can be made by telephoning (01-743-2030 Ext 547)

Closing date 19 September 1985.
(7485)A

UNIVERSITY OF LEEDS DEPARTMENT OF PHYSICS POSTDOCTORAL RESEARCH FELLOW

(Astrophysics)

Applications are invited for the above post for work with Dr A Hillas on modelling the emission ultra high energy (10000 TeV) radiations from Cygnus x-3 and related objects, as a probe of the environment of close binary stars, and gain insight into the origin of cosmic rays.

Applicants should have a PhD or relevant research experience. The post, funded by the SERC, is available for a fixed term of up to two years.

Salary within the range £7,520 - £8,920 (under review) on the 1. Range for Research and Analogous Staff according to age, qualification and experience.

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 52/33, closing date for application 12 September 1985. (7442)A

UNIVERSITY OF CAMBRIDGE POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for a postdoctoral research assistant to work on the processing of transcripts of chloroplast DNA from higher plants. This will include the removal of introns from transcripts of protein-coding genes. Experience of molecular biology techniques would be an advantage. The position which is supported by SERC, is for a period of three years from 1 October 1985, or as soon as possible thereafter. The salary will be on the National 1A scale.

Applications with curriculum vitae and the names and addresses of two referees should be sent as soon as possible to Dr J C Gray, Botany School, University of Cambridge, Cambridge CB2 3EA, from whom further details may be obtained
(7483)A

ASSISTANT EDITOR

Leading German scientific/technical publisher seeks young science graduate (preferably chemistry, physics) with excellent command of English (native speaker) for editorial duties (initially copy editing) related to English-language subscription journals in the area of analytical chemistry, analytical instrumentation, etc. Previous publishing experience highly desirable, knowledge of German advantageous. Location will be in historic city in South-West Germany. This vacancy is to be filled in the near future.

Applications with CV and photo to Box Number W2131, c/o Nature, 4 Little Essex Street, London WC2R 3LF.

GRANTS & SCHOLARSHIPS

**UNIVERSITY OF
NOTTINGHAM**

**Department of Applied
Biochemistry & Food Science**
**MAFF POSTGRADUATE
SCHOLARSHIP**

**Development of Methodology
for Meat Identification in Foods**

Following demonstration that the concentration of 3-methyl-L-histidine provides a robust, unequivocal index of the proportion of animal protein in foods which have been too severely processed to permit the use of electrophoretic or immunological techniques, the methodology has been refined and developed. Further investigation of this, and related procedures in food analysis is being supported by a Postgraduate Scholarship over the 3-year period 1985-88.

Remuneration (and appropriate allowances) will be at the rates advertised in "Postgraduate agricultural scholarships, 1985," Ministry of Agriculture, Fisheries & Food, London.

Applications are invited from those holding a 1st or upper 2nd class honours degree in Food Science, Chemistry or Biochemistry. Experience in column chromatography (preferably in high performance liquid chromatography) would be an advantage.

The successful applicant will be expected to read for the PhD degree of the University of Nottingham under the supervision of Professor R A Lawrie.

Applicants should send a cv (including the names of 2 academic referees) to the Secretary, Faculty of Agricultural Science, University of Nottingham, Sutton Bonington, Nr Loughborough, LE12 5RD (7470)H

WRC/UWIST John L van der Post Fellowship in Biotechnology. Stability of cloned catabolic genes and recombinant host bacteria in activated sludge. Applications are invited for the above Fellowship which is funded for three years by the Water Research Centre (WRC) to start from January 1 1986. Applicants should have a PhD, or expect to obtain one by the starting date, in microbiology, genetics or a related discipline. Experience of recombinant DNA techniques would be a definite advantage. The research, which will be carried out at both UWIST and WRC Processes laboratory in Stevenage will be supervised primarily by Dr J C Fry and Dr A J Weightman of UWIST. Advice will also be given by other UWIST and WRC staff when required. The project will involve the application of techniques for genetic manipulation to the analysis of heterogeneous microbial populations into which defined genetic markers will be introduced. The effects of manipulations on the stability of cloned genes encoding enzymes of halogenated aromatic catabolic pathways will be examined. Survival of recombinant host bacteria inoculated into laboratory and larger scale activated sludge plants and cloned gene transfer in the mixed microbial culture will be analysed by DNA hybridization and fingerprinting techniques. The Fellowship will be on the research and analogous staff scale 1A and will start in the range £7,520—£12,150 according to age. Applications in the form of a letter of application, a CV and the names of two referees should be sent to: Dr J C Fry, Department of Applied Biology, UWIST, PO Box 13, Cardiff CF1 3XF. Further details can also be obtained from the above address if required. The closing date for applications is 13 September 1985 (7476)F

nature FIRST CONFERENCE IN JAPAN

◎ January 20 ⇒ 22, 1986

◎ Keio Plaza Hotel, Tokyo, Japan

ature is pleased to announce a conference on the future of molecular biology and its applications to biotechnology and medicine, to be held at the **Keio Plaza Hotel, Tokyo, Japan**, January 20-22, 1986. The conference will be addressed by distinguished molecular biologists from the United States, Europe and Japan.

The speakers from the United States will include Nobel Prize winners **James Watson** (*Cold Spring Harbor*), who (with F.H.C. Crick) first suggested the structure of DNA, and **Walter Gilbert** (*Harvard University*). Other speakers include: **Stanley Cohen** (*Stanford University*), **Tom Blundell** (*Birkbeck College, London*)

Walter Gehring (*University of Basel*)

Richard Lerner (*Scripps Clinic, La Jolla*)

Sydney Brenner (*Laboratory of Molecular Biology, Cambridge*)

Susumu Tonegawa (*Massachusetts Institute of Technology*)

Shosaku Numa (*Kyoto University*)

Tasuku Honjo (*Kyoto University*)

Ken-ichi Matsubara (*Osaka University*)

Yoshiki Hotta (*University of Tokyo*)

Mitsuaki Yoshida (*Cancer Research Institute*)

Tadatsugu Taniguchi (*Osaka University*)

Hisayuki Matsuo (*Miyazaki Medical College*)

Tokindo Okada (*National Institute for Basic Biology*)

The three main topics to be covered by the conference are

- Molecular biotechnology
- Development and regulation
- Immunology and virology

and the programme is being designed to provide an opportunity for those working in industry, medicine or academic research to bring themselves up to the forefront of research through discussion with world leaders. There will be ample time for questions and discussion. Simultaneous translation services into English and Japanese will be available.

Registration fees:
¥80,000 (before 30 November, 1985)
¥100,000 (after 1 December, 1985)

EARLY HOMO ERECTUS

Mass ion

The new force in b

ZetaPrep® Technology. Engineered for mass ion exchange. Powered with a unique solid matrix. Thrusting you in to a new age of upstream purification. Boosting mass flow and volume flow with results that outdate every other known separation method. Giving you quantum savings in time and money.

Unique solid matrix!

Designed for highly efficient, ultra-fast extraction of proteins, peptides and enzymes, the ZetaPrep solid matrix comes in a cartridge that's completely self-contained. With its unique, multi-directional radial flow, this patented rigid format offers optimal surface area for rapid bulk binding, plus the strength to withstand high flow rates.

All ZetaPrep housings and cartridges are completely sterilizable and compatible with standard equipment. Shown here is the ZetaPrep 100 for laboratory separations.

Economics you just can't ignore!

Capable of one-step purification and concentration with up to 80% purity or more, ZetaPrep will slash your production costs to a fraction of what they are today. Because ZetaPrep is so easy to operate, simple to automate and efficient in use, you'll cut expensive man hours to a minimum.

ZetaPrep's incredible flow lets you radically reduce total processing time. Gets you fast binding, wash and elution flow rates. And at least 10 times higher throughput. With no more packing problems. No more fines removal. Just all the benefits of a totally enclosed system—and yields that are truly astounding.

Amazing scale-up potential

LKB's comprehensive range of ZetaPrep cartridges and Multi-Cartridge Systems lets you select different sizes, extend in series or even couple in parallel for virtually unlimited flow rate and process capacity. With DEAE, QAE and SP functional groups, you can now exploit this amazing scale-up potential from lab, through pilot to fullscale industrial production. In biotechnology, pharmaceuticals or any other process that needs cost-effective purification of proteins and biopolymer products.

exchangeTM

process engineering!

Scale up to 720 liters per hour

Seeing is believing!

Find out how much you can win. That'll convince you just why ZetaPrep Technology has been so successful in such a short time. Why many of the world's leading biotech and drug companies have gone from initial trials to routine industrial processing in just a few months. Why you should try ZetaPrep yourself. Post this coupon today, and we'll send you technical information, full details on test kits available and all prices. Your nearest LKB office delivers fast.

Available also in plastic housing, this ZetaPrep 3000 Multi-Cartridge System, is used for full-scale industrial bioprocessing.

ZetaPrep is manufactured for LKB by AMF Molecular Separations Division. **AMF**

Something Special

Imagine the world's simplest operating ultracentrifuge. Add the most reliable drive ever designed—the Ultra-Smooth vacuum-encased induction system. Include automatic "Soft-Start," built-in diagnostics and the ability to run every Beckman high performance rotor. Top it off with a most attractive purchase price. And you have the new Model L7-55—the one you have been asking for.

With speeds to 55,000 rpm, forces to 408,000 *g*, integrated circuit logic and remarkably

simple controls, the L7 is ideal for everyday applications. It's the perfect addition to the Beckman family of induction drive ultracentrifuges, joining the premier L8M models—the ultimate in centrifugal research tools—and the Benchtop TL-100 for rapid microvolume separations.

Use the L7 for the routine jobs. Save your L8M for investigations where microprocessor control and memory are an advantage, where delicate gradients call for acceleration/deceleration versatility, where computer

interfacing is needed for remote control or record keeping. When you want to cut run times for these jobs by more than half, use the TL-100.

The workaday Model L7-55: it's something special—especially for you!

To get better acquainted, ask for Brochure SB-667. Beckman Instruments, Inc., Spinco Division, 1050 Page Mill Road, Palo Alto, CA 94304.

Antisera to cytoskeletal proteins

among more than 400 quality products
developed and manufactured by

Bio-Yeda

Bio-Yeda's large product range keeps you at the forefront of biotechnology—and the reasons are quite clear:

Bio-Yeda is a pioneer in the field of cytoskeletal protein antibodies. Far ahead of the competition, the company is on the leading edge of scientific research.

In fact the chances are excellent that you have already used Bio-Yeda's high quality immunochemical and biochemical products. They are sold all over the

world under names you'd recognize on any reagent shelf.

Bio-Yeda's expertise begins with its unique association with the renowned Weizmann Institute of Science, and the company's own powerful R&D facilities.

The products developed and produced by Bio-Yeda include a comprehensive range of conju-

gates, monoclonals, antibodies to human and animal proteins and antisera to hormones and drugs.

For further information and a detailed Bio-Yeda catalog, call your nearest Authorized Bio-Yeda Distributor, or contact Bio-Yeda directly.

Hot on delivery...

...cold on arrival

When you order molecular biologicals from Pharmacia you'll find we're pretty hot on delivery.

We'll dispatch your order as soon as we get it, packing it carefully in wet or dry ice.

Now our enzymes are supplied in screw cap mini vials with new waterproof labels, and will easily fit into your centrifuge

tubes and freezer trays.

At Pharmacia Molecular Biology Division that's all part of the service. We realize that the success of an experiment depends on the quality of the products used and the speed at which you get them. With us you'll find that the only thing kept on ice is your product - not your

experiment.

Contact us today and we'll send you our free catalogue with details of over 800 molecular biologicals.

Pharmacia... your partner in molecular biology.

NATURE VOL 316 29 AUGUST 1985

A coloured replica of *Homo erectus* skeleton KNM-WT 15000, the most complete early hominid skeleton yet found. Discovered near Lake Turkana in Kenya, it was excavated from sediments dated at 1,600 million years old. Colour code: fawn, parts modelled in mirror-image; yellow, parts added for mounting purposes only, green, intervertebral disks, epiphyseal plates and filler on the cranium for casting purposes. See page 788.

SCIENCE IN AUSTRALASIA

Australia and New Zealand are most alike in their great distance from everywhere else. Both maintain scientific establishments comparable with those of Europe and North America. In *Nature's* special Australasian issue, Alun Anderson and John Maddox describe their special problems and particular achievements in research and development, and recommend what should be done.

Copies of this special issue are available now.

Australian orders should be sent to:

John Rosenbloom, Macmillan Co. of Australia Pty Ltd., Locked Bag 12, South Melbourne 3205, Victoria, AUSTRALIA. Telephone: (3) 6998922.

Please enclose remittance of A\$6 per copy.

Prices and order address for other countries are set out below.

GUIDE TO AUTHORS

Authors should be aware of the diversity of *Nature's* readership and should strive to be as widely understood as possible

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an italic heading of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or Washington. Manuscripts should be typed (double spacing) on one side of the paper only. Four copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc., should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc., should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts, in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963-65). The first and last page numbers of each reference should be cited. Reference to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Requests for permission to reproduce material from Nature should be accompanied by a self-addressed

UPDATE IN MOLECULAR BIOLOGY 1985

Genes and Systems in Development

You are invited to join a select group of participants and some of the world's foremost speakers at NATURE's fifth international conference.

Presented in conjunction with the University of California at San Francisco.

**OCTOBER 7, 8, 9, 1985—SHERATON-PALACE HOTEL
SAN FRANCISCO, CALIFORNIA**

The 1985 conference presented by NATURE, the international weekly journal of science, in association with the University of California at San Francisco will address what is perhaps the central unanswered question of biology today: How is the process of development directed by genes?

For three days, you will meet and listen to preeminent scientists, physicians and biotechnologists describe their research and first-hand involvement in experimental approaches involving the application of molecular biology to systems and organisms. Topics will include the diagnosis and therapy of genetic defects, homeotic genes, yeast development, development of the immune system—including T-cell receptors—and the use of new biological materials in medicine and industry. Roundtable discussions will be held each afternoon to give delegates ample opportunity to mix with and question the speakers. Participants will have an opportunity to take part in detailed discussions and present their own ideas. Poster presentations are also being invited.

WHO SHOULD ATTEND

Senior Level Scientists, Medical Research Scientists, Biotechnologists, Scientific Policy Makers, R & D Scientists, Departmental Chairpeople.

TO REGISTER FOR THE CONFERENCE

Return the form with your check, credit card authorization, or an authorized purchase order.

Full 3-day registration fee. \$375.00

Pay only \$350.00 if you register before September 15.

LOCATION

The Sheraton-Palace Hotel located at 639 Market Street is convenient to the business and financial districts as well as downtown's most stylish shops and finest restaurants. Since its opening in 1875, this elegant hotel has hosted such world figures

as seven U.S. presidents, Winston Churchill, Nikita Krushchev, Sarah Bernhardt, Enrico Caruso and Oscar Wilde.

ROOM RESERVATIONS

A large block of rooms has been set aside for attendees at preferred rates. However, we suggest you make your reservations early as delegate places and accommodations are filling fast. Rooms can be reserved directly with the Sheraton-Palace Hotel by calling 800-325-3535. Be sure to mention your participation in the NATURE 1985 Conference to qualify for special rates. Singles: \$95. Doubles: \$105 and \$115.

CMEs WILL BE AWARDED

Extended Programs in Medical Education of the University of California School of Medicine in San Francisco designates this continuing medical education activity for 18 credit hours in Category 1 of the Physician's Recognition Award of the American Medical Association and the Certification Program of the California Medical Association.

YOUR REGISTRATION FEE COULD BE TAX DEDUCTIBLE

CONFERENCE DINNER

Our gala Conference dinner will be held Tuesday, October 8, in the historic, glass-domed Garden Court. To insure seating, please include your dinner ticket requirements and payment of \$29.50 per person with your registration.

EXHIBITS

A major exhibition of scientific products and services will be held in conjunction with the Conference.

POSTER SESSIONS

To have your poster considered, please include a working title and brief synopsis of your topic and send to Posters Editor, Nature Publishing Company, 65 Bleecker Street, New York, 10012

FINAL PROGRAMME

Genes and Systems in Development: Nature Update
in Molecular Biology, Sheraton Palace Hotel, San
Francisco, 7-9 October 1985.

DAY 1 MONDAY, 7 OCTOBER

8 45-8 50	Chairman	
8 50-9 40	<i>Drosophila</i> early development	<i>C. Nüsslein-Volhard, Max Planck, Tübingen</i>
9 40-10 30	Genetic control of <i>Drosophila</i> development	<i>D. Hogness, Stanford University</i>
10 30-11 10	COFFEE	
11 10-12.00	Comparative expression of homeobox genes in fly and mouse	<i>W. McGinnis, Yale University</i>
12 00-1 30	LUNCH	
1 30	Chairman	
1 30-2 15	Cytoplasmic localizations in the amphibian egg	<i>J. Gerhart, University of California, Berkeley</i>
2 15-3 00	Genes that control nematode cell lineage	<i>H.R. Horvitz, Massachusetts Institute of Technology</i>
3 00-4 00	ROUND TABLE with day's speakers	
4 00-4 30	TEA	
4 30-5 30	Closing talk	<i>G. Stent, University of California, Berkeley</i>

DAY 2 TUESDAY, 8 OCTOBER

8 45-8 50	Chairman	
8 50-9 40	A master regulatory locus that determines cell specialization in yeast	<i>I. Herskowitz, University of California, San Francisco</i>
9 40-10 30	Regulatory proteins in bacteria and yeast	<i>M. Ptashne, Harvard University</i>
10 30-11 10	COFFEE	

11 10-12 00	Simple and combinatorial regulation of gene transcription	<i>K. Yamamoto, University of California, San Francisco</i>
12 00-1 30	LUNCH	
1 30	Chairman	
1 30-2 15	Control of animal growth by gene transfer	<i>R. Palmiter, University of Washington, Seattle</i>
2 15-3 00	Models for human gene therapy	<i>T. Friedmann, University of California, San Diego</i>
3 00-4 00	ROUND TABLE with day's speakers	
4 00-4 30	TEA	
4 30-5 30	Closing talk	<i>E. Jaworski, Monsanto Company</i>

DAY 3 WEDNESDAY, 9 OCTOBER

8 45-8 50	Chairman	
8 50-9 40	Structure analysis of T-cell recognition	<i>M. Davis, Stanford University</i>
9 40-10 30	Expression of immunoglobulin genes in transgenic mice	<i>U. Storb, University of Washington, Seattle</i>
10 30-11 10	COFFEE	
11 10-12 00	Proto-oncogenes: the good and the bad	<i>J.M. Bishop, University of California, San Francisco</i>
12 00-1 30	LUNCH	
1 30	Chairman	
1 30-2 15	Cell recognition during neuronal development	<i>C. Goodman, Stanford University</i>
2 15-3 00	Molecular insights into mammalian systems	<i>F. Bloom, Research Institute of Scripps Clinic</i>
3 00-4 00	ROUND TABLE with day's speakers	
4 00-4 30	TEA	
4 30-5 30	Closing talk	<i>D.W. Martin, Genentech</i>

Spying is getting out of hand

State Department allegations of Soviet surveillance in Moscow will cause much more trouble than the technique can have been worth. The time has come to agree a code of conduct for spies.

JUST as science fiction has a tendency to become fact, the literary genre of the spy thriller is turning into a curious kind of reality. So much is clear from the US State Department's claim last week that the members of its embassy's staff in Moscow have been contaminated with a chemical (mtrophenylpentadiene) which can be made to be fluorescent by irradiation in the ultraviolet. The allegation, on which further details are promised, is that the material has been planted in people's clothing and on, say, the steering wheels of motor cars in such a way that drivers' hands are likely to be contaminated. The announcement lends credence to the idea that, by means like this, it would be possible for Soviet security authorities to learn what members of the US embassy are about during the course of their working day.

There are several things to say, of which the first is that such a practice would be a serious infringement of the rules that should govern the conduct of diplomatic missions, laid down by the Vienna conventions on the subject. The principle is (or should be) that even people who work as diplomats in foreign countries are, like their hosts, entitled to a measure of personal privacy and to the presumption that they are not criminals — unless evidence to the contrary comes to light. That is why the agreements governing the conduct of embassies usually allow for people's freedom to travel within a certain well-defined area, and entail the assumption that meetings with local residents are by definition innocent unless discovered to be otherwise. A little reflection will show that the whole business of international diplomacy would grind quickly to a halt if these assumptions were not valid. Seeking to provide continuing surveillance of what foreign diplomats are up to, as the Soviet Union may have been doing, would be a serious breach of these important principles.

But even if the allegations are borne out by further evidence, what in principle will have been accomplished? The use of chemicals fluorescent in the ultraviolet has a minor place in forensic science as a means of marking objects whose origin is known, but a more conspicuous place in the luxuriant detective-story literature of the West. The obvious difficulty, in the scheme the Soviet authorities are said to have used to track the movements of members of the US embassy in Moscow, is that there is no obvious way in which generalized use of the fluorescent chemical could possibly have been of value to them. It is unthinkable that the authorities could have scoured Moscow with ultraviolet lamps, looking for traces of US diplomats whose clothing had been doped with the tracking chemical. What would be possible is to tell whether some otherwise unknown person seen seated in some public place had been a US diplomat, or whether a particular high-denomination currency bill (a dollar or a rouble) had been peeled off a stack of notes by a person carrying the tell-tale chemical on his fingers. In other words, if such a chemical has been used and has been found

useful by Soviet counter-intelligence authorities, it is more likely that its function has been to help tell what Soviet citizens have been doing than to keep a permanent watch on the movements of US diplomats. But the chances are that a technique like this would have been of only marginal value in the legitimate prosecution of counter-intelligence by the Soviet authorities. If real, the allegations probably point to some over-zealous and impracticable scheme suggested by an over-enthusiastic committee.

Even if diplomats elsewhere are unlikely to be exposed to hazards of this kind, because other police authorities are unlikely to copy the bizarre technique now described, there is not much else that is cheerful at this stage. If the details of the allegation are borne out, they are bound to sour the climate in which the Soviet Union and the United States approach the next few critical months of conversation about arms control, and about their general relationship with each other. That is the opposite of good news. In the United States, thrown into anxiety about national security by recent cases of espionage and by fears that foreign nationals, diplomats and others increasingly function as espionage agents, the result of the disclosures from the Moscow embassy may be to amplify still further the demand for extra restrictions on the movement of people away from the places to which they are formally posted. And the result of that would be a further twist in the depressing game of tit-for-tat that has characterized the relationship between the Soviet Union and the United States for too long now.

So, in a sense, the best hope is that the allegations now made by the State Department turn out to be untrue, or that while the details may be verified, the implication that chemicals have been used as a means of keeping track of diplomats may be mistaken. Unhappily, that is unlikely to be the case. But there is a chance that the Soviet leadership will be able to argue, with reasons given, that any such practices were carried out without its knowledge, perhaps by junior people in some over-eager part of its establishment. Even that would be a great deal to ask for; the Soviet Union has never been happy to confess to imperfections in its way of running its own affairs. Yet this, it seems probable, will be the only escape the government of France will have from the allegations in New Zealand that French agents were somehow involved with the sinking of the Greenpeace vessel at the end of June.

Espionage and its elaborations (sinking ships, assassinating people) may seem to governments necessary to their domestic security but they are also a threat to international security. Is it entirely unthinkable that they should be regulated by international treaty? The obvious difficulty is that all governments engage in espionage but insist that their hands are clean. That is increasingly a sick joke. Moreover, there are at least some circumstances in which the reality of espionage is acknowledged, as when governments trade groups of captured agents at the Berlin Wall or elsewhere. Why not go the obvious step further, and negotiate a kind of code of conduct for intelligence services. An agreement not to take direct action against third parties (such as Greenpeace) would not, after all, constitute an admission that other less foolish practices are matters of routine. President Reagan and Mr Gorbachev might usefully spend a few minutes on the topic at their meeting in November. □

Biological manuscripts

Contributors are reminded that, with the transfer of the Biological Sciences Editor to the Washington office, they should in future send four copies of all manuscripts offered for publication either (as at present) to London or to Washington.

Upsetting apple-carts

The British research establishment is ripe for a shake-up. Here is one recipe.

THE past year has been a bigger trauma for the British research community than even its immediate predecessors, dominated as they were by the dwindling value of the funds available for research. Now, perhaps not before time, structural change is in the air. Several unrelated issues have come to the boil at the same time. The Science and Engineering Research Council, with a new chairman and a substantially changed membership (see p. 756) must soon produce a plan for the years ahead that will give the largest of the research councils a coherence that will hold it together in the face of centripetal tendencies born of its complexity. The University Grants Committee is committed to a plan for concentrating financial support on the universities strongest in research, but neither the committee nor its dependants know how the system will work. The Advisory Board for the Research Councils (ABRC) is busily putting out fires where it can find them, and is for example embarked on an inquiry into the plight of the British Geological Survey, the largest single component of the Natural Environment Research Council (NERC), but seems not yet to have attempted the more urgently needed inquiry into its own constitution.

The immediate effect is that people in laboratories have been painfully reminded of the fate that has already befallen some thousands of researchers and academics, whose jobs have melted away in the past few years. But as the whole world knows, there is nothing so demoralizing as uncertainty. It is in everybody's interest that the changes now under way should be carried through quickly. Things have reached the point at which almost any decisions would be better than the continuing indecision that seems to grip the establishment. There is nothing new in the recipe for change that follows, most of which has been advocated in the past year or more. Other recipes might serve the same purpose. The need is that somebody should pick one of them and stick to it.

Money. The government has kept its promise of five years ago that research council budgets would stay constant, and there has even been some extra money for earmarked purposes such as information technology. It is intolerable that there should have been so little substantial help with the reorganization of laboratories forced on the Agricultural and Natural Environmental Research Councils in the past few years, for the government has thus allowed what it considers to have been past mistakes to cast a shadow over the health of the whole enterprise. But people had better learn to live with the notion that there will be no extra funds. But reorganization is necessary for other reasons than financial shortage.

Management. The touchstone for the past dozen years in the management of British civil science has been the Rothschild principle, by which government departments, proxy "customers" representing the interests of the end users of research, commission much of the work carried out in civil research establishments. That principle is now dead, as shown by the ease with which government departments have been able to walk away from research institutes they had previously supported. (The British Geological Survey is that most conspicuously left high and dry by departmental fickleness of this kind.) So there is a need for other mechanisms for supporting important and creative work. To detach some parts of the publicly supported research network altogether from the government would make sense. ("To privatize" is the fashionable verb.) The Plant Breeding Institute, perhaps the most immediately productive of the agricultural research council's establishments, is the obvious candidate if it were allowed also to enjoy the income generated by its findings through the National Seed Development Organization; why does nothing happen? But if the government hopes that the cost of public research could be drastically reduced by hiving off large chunks of it, that ambition should be suppressed. Nor is there as much hope as there may seem in

schemes for encouraging parts of the research enterprise to compete for research contracts with private industry; the universities and private research organizations are now eagerly exploiting that market, the former at cut-price rates. Deciding what parts of the public research network to keep and to cherish, and what parts to close down, is an urgent need. Since many of the neglectful government departments are probably mistaken in their indifference to research, the British government corporately should take a view on the wisdom of transferring organizations such as the institutes responsible for geological survey and oceanography back to where they came from (the Department of the Environment and the Royal Navy, respectively).

Leadership. One of the contributory causes of the present decline of British science is that working scientists no longer have a sense that there is a powerful and influential group of people looking out for the well-being of their work. The heads of the research councils are mostly reasonable men, but are undemonstrative and, by tradition, are also anxious not to give the impression publicly that they seriously dissent from the way in which science is being managed, or mismanaged. The result is that they seem to their constituents more like civil servants than the spokesmen of their subcommittees. In the peculiarly British environment, the Royal Society might most suitably play this role. But would the task of helping to point the scientific enterprise in the right direction be feasible within the convention of politeness to which the society is committed?

Institution. Many of the organizations responsible for the direction of civil research in Britain have outlived their usefulness, or have reached the point where only substantial change will fit them for what emerges as their purpose. ABRC itself is a point at which reform should start. The council is too large to be a workable committee, and too representative of conflicting interests to be an effective way of settling contentious issues. To the extent that the council's function is to advise the Secretary of State for Education and Science, one man would suffice. To the extent that it is necessary to put forward the opinions of the users of what the research councils provide — that there should be some predetermined pattern of spending — a handful of outsiders would be the ideal. To the extent that the council should have a part to play in helping to understand what is happening to British research, there is a need for a more effective secretariat than at present. All this is roughly what Sir Douglas Hague, the chairman of the Economic and Social Research Council and one of the members of ABRC, was saying when he joined the council two years ago. Why have his fellow members not listened to what he was saying? And why have the same people not understood the case for disbanding NERC, the research council that had the bad luck to be set up with terms of reference too ambitious for the components with which it was endowed.

Coordination. One of the chief diseconomies in the present organization of research in Britain is that there is no way in which the different parts of the research enterprise can be meshed with each other. Defence research is an entity on its own (but change may be on the way). And separate government departments continue to maintain laboratories and research institutes which become, as morale sinks deeper, more separate from each other than they have ever been. The National Physical Laboratory, dependent on the Department of Trade and Industry, has been in its time a powerful stimulant of research in universities and elsewhere. It is still a worthy place, but much less a laboratory to be proud of. That, too, is a field ripe for reform.

On the face of things, it would be for the government to put these things to right, just as it has fallen to the government to decide what should next be done about the renegotiation of the British relationship with the European high-energy physics laboratory (CERN) at Geneva. But no doubt from depression, the country's capacity to make decisions seems to have been undermined. The notion that any decision is better than indecision is, of course, dangerous; it provides a licence for foolishness. That is why the scientific community itself should find some way of taking charge of events, such as they are. □

Ballistic-missile defence

US under pressure from Europe to share data

Washington

Now that negotiations on allied participation in the Strategic Defense Initiative (SDI) have begun in earnest, the US government and the Pentagon are coming under strong pressure from the British and West German governments to grant full access to technical know-how gathered in the course of the development as part of the price of overseas participation. But the British government has also raised the possibility that participation might not be worthwhile unless the value of the contracts awarded to British companies and research organizations reaches some predetermined value — \$1,500 million has been mentioned, to the consternation of some administration officials.

The report that the British government is asking for contracts worth at least \$1,500 million appeared last week in the *Baltimore News* newspaper and has been obliquely confirmed. But British officials have said that any figure mentioned at this early stage should be regarded as an "opening bid", rather more an indication of the scale on which the Pentagon should be thinking than as an ultimatum.

Negotiations appear to be at a relatively early stage, with the arrangements for dealing with the security of classified information during the research phase of SDI agreed but not yet formally adopted. One of the points made by British negotiators is that any involvement of British companies as contractors for SDI will involve the British government in supervision and monitoring on a substantial scale, the cost of which would be far from negligible. But the chief concern is that companies or other research entities involved with SDI should not be dealt with as mere research contractors and recompensed on the basis of the time and trouble expended, but that they should be genuine partners in the parts of SDI in which they are engaged.

SDI is likely to centre on fields such as infrared sensors (the basis of boost-phase detection) and signal-processing, in both of which British defence research establishments and associated defence manufacturers have some expertise. One of the British demands is that there should be no restraint and British companies should not be at a disadvantage, compared with US participants, in the later exploitation of developments in which they have been engaged.

A more distant and more difficult issue, raised chiefly by the government of West Germany, is whether governments and national companies participating in SDI should also have access to the later com-

mercial exploitation of technical innovations in which they have not been directly involved.

Even though these questions have not yet been decided, the United States

appears to be in some haste to bring the negotiations to a conclusion. With the sequence of diplomatic meetings planned for next month and thereafter, the bilateral summit in November chief among them, there are obvious benefits in being able to announce allied participation in SDI. No doubt the potential partners have made similar calculations. Just what price will be struck for the political advantage and the technical assistance may be the kind of question the game of poker is designed to answer. □

UK overseas students

Market forces shrink demand

FIVE years after the British government's decision to require overseas students to pay a full "economic" rate for their college or university education, the numbers are still in decline. A report from the Commonwealth Secretariat estimates that the number of overseas students has dropped to some 55,600, a fall of more than 30,000 since the introduction of full-cost fees in 1980, including a fall of 1,000 last year.

Despite a declaration from Commonwealth education ministers meeting in Nicosia (Cyprus) last year that it is important to foster the exchange of students between member nations, the Commonwealth Secretariat notes that exchanges within the Commonwealth are on the decline, but that elsewhere student mobility is increasing. West Germany now accepts 72,000 foreign students and appears to be taking more students from Commonwealth countries no longer able to send as many to the United Kingdom — including Cyprus, Tanzania and Kenya.

The United States remains by far the largest host nation, with some 340,000 foreign students. France has more than twice as many as the United Kingdom (128,000) and the Soviet Union has 82,500. Japan, at present with some 10,000 foreign students, plans to expand this to 100,000 by the end of the century.

The foreign policy implications of providing places for overseas students were recognized by the British government in 1983 when, after considerable pressure from the Commonwealth (most vociferously from Malaysia), the then Foreign Secretary Mr Francis Pym announced a three-year £46 million package to subsidize overseas students. The "Pym package", now entering its last year, singles out certain countries as specially deserving cases—Cyprus, for instance, with a large refugee population, no major university

and strategic importance to Britain — as well as potentially influential individuals from potential trading partners.

The clear determination that the United Kingdom should get "value for money" for overseas students supported financially underlines the economic problem of fostering an exchange between the developed and developing nations. With a brief that the mobility of students between Commonwealth countries is a good thing no matter in which direction the movements take place, the committee responsible for the report suggests that the less developed countries with relatively sophisticated university systems might be encouraged to take increasing numbers of students from countries with few universities.

Not only the supply of university places is affected by economic pressures. Shortage of foreign currency means that the demand is also depressed in countries such as Nigeria and Malaysia, even if the cost of education in host nations is not increasing.

In the immediate future, the current trend in Britain seems likely to continue, as fees are due to increase by a further 5 per cent for the year 1985–86. But for the long term, the committee raises the possibility that student exchanges may not be indispensable for sharing the access to high-level institutions. New information technologies, says the Commonwealth Secretariat, should be considered as an alternative. If the best learning in the world is available at the nearest computer terminal and telephone line, will there be any need for the students to stir from home?

Charles Wenz

"Commonwealth Student Mobility: A Way Forward", is the fourth report of the Commonwealth Standing Committee on Student Mobility (Commonwealth Secretariat, Marlborough House, London SW1 5HX, UK).

Australian budget

Modest gains for science

Canberra

THE federal government's budget, made public last week, allows modest gains for the government's chief science agencies at a time when the general theme is that of restraint. Indeed, with inflation between 7 and 8 per cent a year, the Hawke government plans to cut its overall deficit to just under \$A5,000 million, some 2 per cent of the estimated Gross Domestic Product for 1986.

According to science minister Mr Barry Jones, the budget for the science portfolio will increase next year to a total of \$537 million, an increase of 6.4 per cent. Within that total, however, there are small but significant shifts of emphasis. The largest single item, the budget of the Commonwealth Scientific and Industrial Research Organization (CSIRO) will be \$A336.7 million which, after allowing for inflation, represents a small cut. No doubt the issue will be reviewed after the appearance of the report on the organization by the Australian Science and Technology Council (ASTEC) expected later in the year.

The chief (if modest) winners from the new budget are the Australian Research Grants Scheme (ARGs), whose budget increases to \$A27.5 million, a rise of 10 per cent. Both the Weather Bureau and the Antarctic Division will have increases of the same size.

Perhaps more significant than these small changes, Mr Paul Keating's budget includes provision for increasing the numbers of students in tertiary education by 20,500. As yet, no decision has been made about the distribution of these places among the three sectors of higher education, but the government announced last week that it had accepted the general arguments of the plan for the reorganization of the Commonwealth Tertiary Education Commission, put forward a few months ago by the commission's chairman, Mr Hugh Hudson. Among other things, Mr Hudson advocated closer integration and liaison among the three sectors.

One unexpected feature of the new budget is that the funds available to the Australian Industrial Development Research Board next year will remain \$A65 million, a reduction of only \$A2 million on this year's budget. It had been expected that these funds would be sharply reduced to offset the plan to introduce, from 1 July next, a 150 per cent tax credit so as to provide manufacturing industry with an incentive to undertake more research and development with their own funds.

For the Australian research community, as for others affected by the budget, the biggest uncertainty for the months ahead is the way in which the economy will respond to the changes that have been made. Mr Paul Keating's plan to engineer

a shift from direct to indirect taxation has now been abandoned. The government was boasting last week of the comparatively rapid economic growth of about 4.5 per cent a year, promising more of the

British research

Bed of nails at last vacated

SIR John Kingman, who has occupied the most conspicuous bed of nails in the British research establishment for the past five years, as chairman of the Science and Engineering Research Council (SERC), leaves this week knowing that his council still has to hammer out a policy for the future. Although impending shortages of

funds sent the council and its staff into an urgent review of priorities last autumn, the resulting "corporate plan" has seemed to the council at its two most recent meetings to be more a list of options than a set of decisions. It will now be for the new chairman, Professor E.J.W. (Bill) Mitchell and the new council (which will have no fewer than eight new members when Mitchell's own place is filled) to decide what lies ahead (see *Nature* 15 August, p.568).

Kingman will become vice-chancellor of the University of Bristol at the beginning of next month. Of the British research enterprise in the past five years, he acknowledges that the British government has kept its promise to keep research spending constant, but that the parallel decline of university budgets had been a serious setback. Now, he thinks, the signs that the rate of emigration of able scientists from the United Kingdom has accelerated again shows that the chickens are roosting uncomfortably.

Politically, there are some hopeful signs. Kingman says, for example, that several Members of Parliament are now more sympathetic than they used to be and conscious that Britain differs from competitors such as the United States and France in attempting to keep science spending constant.

But he also considers that the British

same to come.

But Mr Keating has also been giving solemn warnings that the inflation rate could be sharply increased if wage settlements seek too much compensation for past inflation. Since the budget spending items now announced are fixed in cash terms, their value could be seriously affected by the inflation rate. □

scientific community has been churlish and tactically unwise in not acknowledging more fulsomely that its paymaster, Sir Keith Joseph, Secretary of State for Education and Science, had made a brave political effort to secure extra research money at the expense of student grants at the end of 1984.

Largely for financial reasons, Kingman's spell at SERC has been the most uncomfortable since the reorganization of the 1960s. It has also been a period of indecisiveness. Even major questions such as the council's future commitment to high-energy physics remain undecided and are likely to be out of the council's hands at least until the British government has decided how a renegotiation of the CERN agreement should be opened.

John Maddox

Trees: No news . . .

BRITAIN'S trees are reassuringly healthy, according to a report published by the UK Forestry Commission last week*. In a £40,000 survey during 1984, the commission found that no new phenomena were needed to explain unhealthy trees. Well-known pests, diseases and climatic influences accounted for all such cases. The survey was started because of increasing environmental damage to European forests, particularly in West Germany.

The main aims of the survey were first to assess major tree species to see whether the patterns of decline were similar to those in West Germany and elsewhere in Europe; and second, to relate the symptoms at particular sites to local conditions, especially with respect to atmospheric pollution. The species assessed in the UK survey were Norway spruce, Sitka spruce, and Scots pine.

The survey covered the whole of Britain, and included stands of 35–40-year-old trees likely to remain undisturbed for at least 10 years. Land was divided according to height, amount of rainfall and amount of sulphur deposition. (Sulphur dioxide was the only potential pollutant included in the survey; there is not enough information available on the distribution of rainfall acidity and ozone, for example, to include them in the study.) The Forestry Commission's subcompartment database was used to combine these data with, for example,

Espionage

Soviet scientist accused

A SOVIET scientist, employed at the Arctic and Antarctic Institute of the State Hydrometeorological Commission, made use of research trips abroad to pass on classified information to United States intelligence, according to *Pravda*. Soviet newspapers are usually reticent about reporting criminal or espionage cases, but this particular story was considered worthy of a three-part serial. During the past two years, the Party *agitprop* literature has paid considerable attention to the risks faced by Soviet sailors and others obliged to travel to the capitalist world. The history of the scientist-spy, Yuri V. Pavlov, (code-name Rolf Daniel) was presumably given such extensive coverage to show that even a highly educated Soviet scientist is not immune to temptation.

Pavlov, according to his own statement, quoted in *Pravda*, was the son of a mining engineer and an English teacher. Born in 1935, he studied in Leningrad, specializing in experimental nuclear physics, but abandoned his dissertation work out of boredom. After being involved for some time in a "fantastic project" to create artificial diamonds using nuclear explosions, he drifted out to the Soviet Far East and then, in 1961, took part in an expedi-

tion to Japan, Tahiti, Fiji and Hawaii aboard the doyen of Soviet research vessels, *Vityaz*. Here, *Pravda* implied, Pavlov proved a misfit, being temperamentally unsuited to carry out serious scientific work without "fanfares or laurels".

He returned to Leningrad and for the next seven years he apparently drifted from job to job seeking good pay rather than interesting work.

For a time, he was employed in what was entered in his official work record book as "secret work and documents". In 1969, he went to work for the Marine Register of the USSR and, in his own words, became "one of the central figures in the atomic inspection of the register". Between 1977 and 1980 he travelled abroad to meetings of an international working party on safety regulations for nuclear ships, visiting London (four times), Genoa, Ottawa and Hamburg. Finally he left this job however, feeling that it was "too narrow" for him and in the autumn of 1981 began working at the Arctic and Antarctic Institute, in order that he might avail himself of the opportunity of foreign travel aboard the research ship *Professor Vize*.

During his travels, Pavlov stated, he was recruited by West German intelligence and the Central Intelligence Agency. The *Pravda* narrative traces out the course of his contacts in foreign ports, the "spy kit" issued to him, the efforts of Soviet counter-intelligence to track him down and his final confession and repentance and the imposition of an (unspecified) appropriately severe sentence" (presumably the death penalty) by a military court.

The exact data which Pavlov allegedly handed over to the West are left vague, but a tailpiece entitled "instead of an epilogue" puts the story firmly in the context of US/NATO "aggression" as revealed by "star wars", psychological warfare and disinformation.

Ceaseless vigilance, says *Pravda*, is the "principal weapon" in this ideological war. Pavlov, on the contrary, exhibited the "lightmindedness" of "ideologically unstable people", who "live in a vacuum" and who must be excised from Soviet society as a "foreign body".

Perhaps the most telling summing-up of Pavlov's character faults, however, comes not in this tailpiece but in the body of the narration, where he is accused of "Manilovism". This word, drawn from the name of a character in Gogol's *Dead Souls*, does, indeed, typify the shiftlessness and lack of stability which, presumably, Pavlov exhibited, but it is a word that has not recently been much in vogue in Soviet character-analysis, having been one of Stalin's favourite epithets of condemnation.

Vera Rich

Nuclear waste

EPA regulates at last

Washington

THE US Environmental Protection Agency (EPA) has at last issued regulations that it wants to see enforced at high-level radioactive waste disposal sites. But the "final" standards are unlikely to be the end of a long inter-agency dispute on how the regulations will be enforced, and there seem likely to be many opportunities yet for opponents of geological disposal to mount legal challenges.

EPA has come out on the wrong side of an argument with the Nuclear Regulatory Commission (NRC) over regulation of disposal sites, the upshot of which is that EPA can only implore NRC to comply with a list of assurance requirements designed to ensure that there will be no significant leakage of radioactivity for 10,000 years after disposal operations are completed. The practices at the disposal sites while they are still in operation will be regulated by NRC, whose standards are different from those promulgated by EPA.

The need for a permanent resting place for US nuclear waste has become urgent in recent years. In 1982, a report from the Congress's Office of Technology Assessment warned that some power stations might have to close down unless provision was made for disposing of high-level waste, mostly used fuel rods, now accumulating in ponds at power station sites. Given the tarnished public image that nuclear power already suffers in the United States, that was an option to be avoided at all costs.

Responsibility for selecting and operating a disposal site rests with the Department of Energy, which is now engaged in processing some 20,000 comments on its proposal to carry out on-site investigations at three possible sites for a high-level waste repository. By the end of the year, the department hopes to have confirmed its previous choices and to have issued final environmental assessments. A final decision will then be made by the President and Congress.

The standards that EPA has now issued limit exposures to members of the public to 25 millirems to the whole body, 75 millirems to the thyroid and 25 millirems to any other organ. There is also a waiver whereby the EPA administrator can raise the 25 millirems limit to 100 millirems if he sees fit or 500 millirems for a one-off dose. And the standards limit projected releases of radioactivity to the environment for 10,000 years; EPA estimates that compliance with the containment requirements means that there will be no more than 1,000 cancer deaths over the entire 10,000 years considered. Tim Beardsley

... is good news

tree species and age, to provide the basis of stratified sampling schemes.

No needle yellowing, such as that found in Norway spruce in West Germany, occurred in Britain. A strong regional effect for crown density and needle age could have been caused by local environmental factors or by bias among surveying teams. Scots pine and Norway spruce hold their needles for longer at higher altitudes but had less dense crowns where rainfall is higher. Scots pine held its needles for longer, but Sitka spruce had less dense crowns, in high sulphur deposition zones. None of these signs of sickness was caused by previously unknown phenomena.

Although the news is good for Britain's trees, optimism should only be cautious. A single survey has limited use in detecting changes in forest health, but patterns should emerge with subsequent re-surveys. West German surveys cannot easily be compared with the UK data because of differences in management, altitude, climate and, particularly, age of trees (old trees are more susceptible to pollution damage). As the trees in the UK survey grow older and the local levels of pollution vary with time, patterns of damage, if they exist, will emerge.

*Forestry Commission Research and Development Paper 142 Forest Health and Air Pollution: 1984 Survey £1.40.

Nuclear India

New reactor "not for bombs"

New Delhi

INDIA has denied reports that the country's largest research reactor, commissioned on 8 August, is intended to breed plutonium for bombs to counter Pakistan's nuclear threat. A spokesman for the Department of Atomic Energy (DAE) says that the 100-MW DHRUVA reactor at Bombay is capable of producing annually 30 kg of plutonium which will be outside international safeguards, "but it is not a dedicated facility". He says that like all uranium-fuelled reactors in the world, DHRUVA will breed plutonium, but is not linked with any weapons programme.

India is not in fact dependent solely on DHRUVA for plutonium if it did decide to go nuclear. It has been reprocessing spent fuel from CIRUS, an ageing Canadian-built 40-MW reactor operating in Bombay, since 1963. CIRUS was the source of plutonium for the nuclear test in Pokran in 1974. Another 100 kg of plutonium, also from CIRUS, was used to make the Pu-U carbide fuel for the Fast Breeder Test Reactor (FBTR) which is nearing completion at Kalpakkam near Madras.

Neither CIRUS nor the first 230-MW unit of the Madras Atomic Power Plant (MAPP-I) which has been operating since 1983 is under safeguards; these apply to the US-built power plant in Tarapur, and the two atomic power reactors in Kota, Rajasthan. While Tarapur fuel has not yet been reprocessed, every gram of plutonium produced at Kota has been accounted for. India's current stock of plutonium is estimated to be at least 200 kg. DAE officials point out that it is not from lack of plutonium but by a political decision that India has not been making bombs.

Four days after DHRUVA became critical, DAE commissioned MAPP-II, the second power plant in Madras. This "90 per cent indigenous" power plant, together with DHRUVA, which will replace CIRUS in five years, will no doubt add to the stockpile of unsafeguarded plutonium which DAE says is required to fuel the fast breeder reactors India plans to build in the 1990s. The FBTR, similar to France's RHAPSODIE, is expected to become critical in September and India is well advanced in the design of a 500-MW prototype commercial breeder.

According to DAE, the DHRUVA reactor will be used to produce isotopes for agriculture and medicine, besides research on solid state which requires a higher flux of neutrons than is available at CIRUS or APSARA—a one MW swimming pool reactor built in 1956 using British supplied enriched uranium. DHRUVA, which uses natural uranium fuel and a heavy water moderator, is designed for a flux of 10^{14} neutrons at the centre of the

core, and is thus comparable to the NRX reactor of Canada. DHRUVA will, however, operate at full power only after DAE has solved the serious problem of vibration of fuel rods and ensured complete safety of the interlock systems. When one of the interlocks failed two days before the reactor went critical, four ton-

The DHRUVA (left) and CIRUS (right) nuclear reactors.

nes of heavy water worth £0.75 million were spilt. MAPP-II, which went critical without a hitch, is expected to be synchronized with the power grid in November. With the commissioning of the country's sixth nuclear power reactor, the nuclear contribution to India's total power capacity will reach 1,320 MW, or four per cent. The target, according to Dr Raja Ramanna, chairman of the Atomic Energy Commission, is 10,000 MW by the year 2000.

K.S. Jayaraman

Soviet alcoholism

Drunk driver stripped of degree

THE Soviet Union's new campaign against alcohol abuse has cost at least one scientist his degree, and the lifelong financial benefits that go with it. The legal provisions, introduced in 1976, allowing those found guilty of conduct unbecoming to a Soviet citizen to be deprived of their degrees, has so far been used only in a handful of cases involving Jewish refusniks.

The penalty has now been imposed in the bizarre case of Boris Samarin, a former employee of Leningrad University, who is just completing a four-year sentence for causing the deaths of six companions while driving under the influence of drink.

The accident, which took place in the small Karelian village of Suoyarvi, involved members of the Leningrad University Karelian Geophysical Expedition, headed by Samarin. On the way back from the expedition, Samarin was travelling in the cabin of the expedition truck, and both he and the driver, Viktor Kolesnik, were drinking heavily. When the truck ran off the road into a swamp, all six people in the body of the truck, three girl students, two women scientists and the small son of one of the latter, were drowned, Samarin and Kolesnik escaped to face the legal consequences.

Court cases are normally reported in the Soviet press only to illustrate some facet of current policy, and it was only last August, more than three years after the

crash, that the Moscow *Literaturnaya Gazeta* carried an extensive article on the incident, pointing out that Samarin was well known to be a heavy drinker, that members of the hydrogeology department were reluctant to go on expeditions with him (indeed, his expeditions regularly included a number of "dead souls", who figured in the official report but who had never actually left Leningrad), and that, nevertheless, no apparent efforts were made to curb his drunkenness nor to take the organization and running of expeditions out of his hands. How, asked the *Literaturnaya Gazeta*, could such a situation arise?

A few weeks later, the newspaper printed a reply from the rector and the secretary of the Party Committee of Leningrad University. This, in effect, pointed out that the unfortunate incident had taken place three years previously, and that as a result of the tragedy, procedures relating to university personnel and to the organization of expeditions had been considerably revised.

Last month, as a postscript to the whole affair, the paper noted that it had received a letter from Dr G.M. Nesmeyanov, the head of the Higher Attestation Committee, VAK, the body responsible for higher degrees, saying that Samarin had now been deprived of the degree of Candidate of Geological and Mineralogical Sciences.

Vera Rich

Environmental organizations

Workings of Greenpeace

THE boats of Greenpeace both symbolize and implement the direct action campaigns by which that group enters some of the world's most highly publicized environmental controversies. Greenpeace's willingness to establish a physical if non-violent presence gives it an "extreme but not extremist" character. "People want to see effective environmental campaigning for their money", says one spokesperson, pointing to press coverage of the group's activities as one measure of fulfilment of that promise.

Although environmental groups sometimes formally pool their resources, such as in the consortium fighting the US sanctioning policy on Japanese whaling, the strength of the environmental movement, according to Peter Wilkinson, member of Greenpeace's international board, lies in its diversity. Greenpeace takes a radical stance amid this diversity, though not as radical as that of groups espousing violence. Alan Pickover, Greenpeace international coordinator for marine animal campaigns, says that the group's position on the outer fringes often serves to push governmental compromises towards the middle ground of environmental opinion, which would not happen if conservative groups such as the Royal Society for the Protection of Birds were the primary environmental voice.

The sinking of *Rainbow Warrior* has not changed Greenpeace campaign priorities, although the loss of the £250,000 investment has resulted in a scramble for campaign funds and rearranged schedules for other ships. Greenpeace offices worldwide, says Mr Wilkinson, have been inundated with messages of support, although the level of contributions has not yet been assessed.

With the loss of *Rainbow Warrior*, which was based in the United States, Greenpeace is left with only two large ships. The older of the two, *Serius*, has just left an aborted attempt in Iceland to stop that country from killing 200 whales next year for "scientific research". Only the first instalment has been paid on the ocean-going tug *Greenpeace*, now on its way to Mururoa and Antarctica. Green-

peace had bought this vessel before *Rainbow Warrior* was sunk and will have to pay the remaining \$360,000 over the next three years. The organization also owns a river-going vessel bought with publicly raised funds and equipped to detect pollution as well as a hot air balloon held by the East Germans ever since it inadvertently sailed over the Berlin Wall.

Greenpeace has offices in 15 countries. For an office to have a vote on Greenpeace policy, it must not only be self-sufficient but also contribute funds to international campaigns. Some of the six fledgling offices have simply not had the time to mature; others, such as the French office, are important for political reasons even if they do not make much money. Every fall, representatives from these 15 countries meet to discuss policy and international campaign budget issues. Their decisions determine the organization's priorities for the coming year as well as setting the official Greenpeace viewpoint on any given issue. An elected international board of five is responsible for monitoring as well as for emergency decisions in the course of the year.

Greenpeace offices worldwide are organized in different ways depending on individual countries' needs and laws. Only in the United States does Greenpeace maintain full-time government lobbyists because policy-making there is amenable to such pressure tactics. In Europe, on the other hand, lobbyists concentrate on international conferences. Each office supports at least one expert in each of the primary areas of Greenpeace activity, but campaign strategy in any area is settled at the international rather than the national level.

International campaign proposals fall into four categories: nuclear; marine animals, which includes fisheries; chemicals; and terrestrial animals. Before the annual meeting, the campaign coordinators responsible for these areas, armed with figures of the available funds, work out proposed budgets with the campaign directors in each area. Greenpeace commissions technical reports and also uses experts on each animal or topic at issue to determine where the greatest needs lie. The compromise decisions that are made at the annual meeting tailor the proposals to stay within the expected income for the coming year. In 1985, 29.1 per cent of direct action money was spent on marine animals, 22 per cent on nuclear, 12.4 per cent on chemicals and 1.1 per cent on terrestrial animals (mostly kangaroo pelts and meat). The high cost of the boats eats up most of the remaining 35.4 per cent; a three to four-day action in the North Sea, for example, costs roughly \$20,000.

Trouble can arise because of unexpected losses such as *Rainbow Warrior* or if offices do not raise the "notional money" they had pledged and which was divided up in the annual meeting setting out goals for that year. After the budgets for running national offices are deducted, the remaining funds from all the offices are pooled to cover Greenpeace's international campaigns. The estimated income for 1986 is \$10 million, with 80 per cent of that available for campaigns. According to one spokesperson, Greenpeace income has been increasing at roughly 10 per cent a year, with the average donation \$10-100 and virtually no donation over \$1,000. There is no extra room in the budget. According to Mr Wilkinson, Greenpeace's bank balance after campaigns is only \$300,000, which represents a dangerously small margin of leeway.

Elizabeth Collins

AIDS

US company rejects UK decision

THE UK Public Health Service (PHS) evaluation of test kits that detect the presence of antibodies to the AIDS (acquired immune deficiency syndrome) virus in the blood has been criticized by one of the companies that did not come out well from the study (see *Nature* 8 August, p.474). Of the five companies whose kits were evaluated, Wellcome Diagnostics (UK) and Organon Teknika Ltd (The Netherlands) were selected for the second stage of the evaluation, testing by the blood transfusion service. By October, all blood donated in the United Kingdom will be screened for the presence of the AIDS virus, probably using one of these kits.

But Abbott Laboratories Ltd, US manufacturers of one of the unsuccessful kits, is not satisfied with the results of the PHS evaluation. The company is lobbying government officials and physicians in the

United Kingdom to persuade them that the results of the survey are "preliminary and misleading". Kits currently available on the US market, which include Abbott's, are almost completely efficient at detecting AIDS virus antibodies.

Whether Abbott's complaint is justified will not be known until PHS publishes the details of its evaluation early next month. If Abbott's test is not one of those recommended by the health department to the health authorities for use in the transfusion service, the company will lose out in a business that is worth £5-10 million a year. Abbott claim to have a prototype kit that detects viral antigen, a test which would enable much earlier identification of people at risk to or carrying the AIDS virus and which is recognized to be the next step in the control of the disease.

Maxine Clarke

Animal intelligence

SIR—According to Geoffrey Hall's review of *Animal Intelligence* (*Nature* 25 July, p.306) "... modern experimental studies of animal learning... have found precious few differences between species that can be unambiguously interpreted as being the result of differences in intelligence. Macphail concludes that we might as well accept ... that extant non-human vertebrates do not in fact differ in intelligence". I would like to support the reviewer's comment that this conclusion is a condemnation of the skills of modern experimenters rather than an accurate judgement of the intelligence of animals. There is surely something very wrong with studies that show no unambiguous differences in intelligence between a frog or a chameleon — or even a sheep — and a sheepdog or a chimpanzee.

Very complex behaviour patterns can be built into the simple nervous system of an insect, a honey-bee can quickly learn to find its nest by what must be a quite comprehensive imprinting essential to the success of its way of life. The ability of a rat to learn its way through a maze may not have much relevance to its intelligence. Young rats may be programmed to learn complex and growing mazes of tunnels.

The primary function of intelligence must have been to improve the chance of survival or it would never have evolved. For a specific way of life in an unchanging environment, a built-in behaviour pattern that has been optimized by natural selection over 5 million years — a typical species lifetime — is not easily improved by an individual creature. Improvement must require occasional replacement of part of the built-in behaviour pattern by an anomalous behaviour locally more successful than the five-million-year optimum. This in turn requires three things. The first is a good memory of events in the individual's life, such as stumbling on a novel source of food in an accidental excursion into a normally avoided environment, or of a narrow escape by novel means from a novel hazard. The second is the ability to recognize the value of repeating the experience. The third is the ability to override the built-in behaviour pattern in order to do so.

The enormous gap between human and even the greatest animal intelligence could mean that we ought to use different words for them, but I believe that the difference is quantitative rather than qualitative. We passed a vital threshold when we became bright enough to carry throwable chipped stone weapons. A group so armed would have become very unattractive to the big predators, and survival from then on must have depended on intra-specific competition for food-bearing territory between groups. This did nothing to make us tolerant of groups of strangers but a lot to increase our intelligence. A second

threshold was passed when we developed language. The value of this in original practical thinking is often exaggerated, but its value in transmission of thought and knowledge and hence in inter-group fighting was overwhelming.

The value of intelligence will be much increased if the environment undergoes a large and permanent change. At the end of the Cretaceous period, the Earth seems to have been struck by a large meteorite and the resulting dust clouds may have persisted long enough to eliminate many species of plants and animals over large areas. The survivors will then have been thrown suddenly into a changed biological environment in which many of the less adaptable species may later have died out. Then those species, for example the early mammals, that could diverge from their built-in behaviour, and learn from their own experience and from novel behaviour of parents or other conspecifics, would have had a great and sometimes overwhelming advantage over those with rigid behaviour patterns.

To measure intelligence we must do

more than measure memory. The ability of a rat to learn a maze is a good test of memory, but could be using the same kind of built-in learning pattern as that of the honey-bee. It would be better to give the rat a chance of some lateral thinking by, for example, painting a particular scent on the wall in the middle of each straight section on the side to which the rat should turn at the next fork. Increased speed of learning another maze with the same cues could hardly result from any built-in pattern. Similar problems could presumably be arranged for a goldfish, a tortoise, or more expensively a chimpanzee.

To summarize, I believe that there are differences in intelligence, which must in principle be observable, between different vertebrates, and that there are understandable reasons why these should have arisen. Furthermore, in testing for intelligence, I believe that one should try to distinguish between memory and the ability to notice correlations between experiences, and should look for ability to override normal or usual types of behaviour.

46 Vernon Road,
Edgbaston,
Birmingham B16 9SH, UK

PhD theses

SIR—A PhD is supposed to be a training in research. Normally this process is conducted over a period of three years, financed by either government or industry, and involves three years' supervision by a university teacher, to which must be added the cost of equipment both capital and consumable, and technical assistance over the requisite period. The return for the many thousands of pounds of outlay per candidate is a thesis on a university library shelf and a piece of paper for the successful candidate which hopefully will enable him or her to command a higher salary than he or she could otherwise have expected.

While it is true that theoretically theses can be consulted in university libraries, in practice this is rarely done. References to PhD theses occasionally appear in the scientific literature, but usually only when an author refers to his own unpublished thesis.

Research is not recognized as having been brought to a conclusion until it has appeared in print in a recognized scientific journal. An essential part of training in research should be the preparation of the work for publication as a scientific paper. A PhD should not be awarded until there is evidence that the major new contributions to science have been published or at least accepted for publication in an appropriate reputable journal. If the material is not suitable for publication then it was not necessary for it to be done in the first place. If there are a large amount of basic data for which there should be ready access, then this could be

deposited in suitable archives as is already the practice with learned societies.

It must surely be time for the antiquated PhD thesis system to be thoroughly overhauled. The stupendous waste of resources cannot be justified at this time. It cannot be beyond the wit of man to devise a system more in keeping with present needs.

Modest disclaimer

SIR—John Maddox's readable account (*Nature* 11 July, p.101) of the experiment that T. Corle and I made to measure Maxwell's displacement current inside a capacitor as it is being charged does us too much credit. Although we may have been the first to measure the profile of the magnetic field between the capacitor plates, we were not the first to measure the total magnetic flux.

That experiment was done almost 60 years ago by M. R. van Cauwenberghe (*J. Phys. Radium* 10, 303; 1929). The title of that work, "Vérification Expérimentale de L'Équivalence Électromagnétique entre les Courants de Déplacement de Maxwell et les Courants de Conduction", aptly expresses the results of a very pretty measurement which used an iron-core, toroidally-wound solenoid to measure the magnetic flux through the central portion of a capacitor.

D.F. BARTLETT

Department of Physics,
University of Colorado,
Boulder, Colorado 80309, USA

Rates of galactic star formation

A remarkably simple argument successfully accounts for the rate of star formation in different galaxies. The snag is that the timescale is uncomfortably short.

How could star formation be infectious, or autocatalytic, "catching" in the vernacular? Simple prejudice says that such a mechanism is too anthropomorphic to be real. But the simple sight of a spiral galaxy such as that of the Milky Way will show that the pattern of star images, but especially that of new stars, has a clumsiness that suggests their congregation. The mass of stars in the Orion nebula argues the same case. The objective way out of this dilemma is to follow Schmidt (originator of the fast sky-camera) in supposing that the rate of star formation is somehow a function of the density of the raw material, interstellar gas. Obviously the functional relationship cannot be linear, for then the ratio of stellar mass to that of the immediately surrounding gas would be uniform in space. Schmidt (*Ap. J.* 129, 243; 1949) suggested that the rate of star formation might be proportional to the square of the density of interstellar gas, or something like that.

Michael A. Dopita, from the Mount Stromlo and Siding Spring Observatories, who has a better autocatalytic idea, points out (*Ap. J.* 295L, 5; 1985) that no relationship of the type proposed by Schmidt can explain why the Smaller Magellanic Cloud has only one fifth as much mass locked up in stars, per unit mass of gas, as has the Larger Magellanic Cloud. Infection, autocatalysis or positive feedback in star formation is his solution.

Suggestions that star formation may stimulate further star formation are far from novel. The mechanics of such a process are easily described. Newly formed stars will heat and even ionize the immediately surrounding interstellar medium, while those massive enough to run through their evolution quickly to form supernovae will add hot material to their environment. The result is that the interstellar medium is filled with hot gas in a set of circumstances, far from equilibrium, in which the colder material in the environment is compressed into clumps that may be massive enough to collapse under their own weight into proto-stars and eventually stars. Dopita refers to several explicit accounts, going back to the late 1970s, of how such a mechanism may account for observed properties of galaxies.

His own contribution is what he calls a "law of star formation" to replace that originally suggested by Schmidt. Time will tell whether it provides a sufficient ex-

planation of the variation of the rate of star formation from one galaxy to another as well as from place to place within a single disk-shaped galaxy. But its immediate virtue is the simplicity of its argument.

To make sense, a law of star formation must link the observed rate of star formation with something else that can be observed. Dopita settles for the surface brightness of neutral hydrogen of a galaxy, or of a part of it, which the radioastronomers are able to measure directly. The essential link between these quantities is simply that of kinetic theory, that the mean squared velocity of the gas is proportional to the pressure.

Dopita's argument then starts from the assumption that the interstellar gas pressure is a linear function of the two quantities representing the mass density of stars and the rate at which that variable changes with time as a consequence of star formation. In gas-rich galaxies (such as both the Magellanic clouds) but also in other circumstances, the rate of star formation will be the dominant determinant of interstellar gas pressure. In those circumstances, Dopita concludes, the total rate of star formation in a galaxy should be proportional to the product of its total mass and the surface gas density (in grams per cm^2 , for example).

The prescription seems to work remarkably well. At least on a log-log plot (of the rate of star formation and the product of total mass and surface gas density), both the Magellanic clouds, our own galaxy and a score of other gas-rich galaxies lie within a factor of less than 10 of a straight line, which is probably as much as can be expected for quantities such as the rate of star formation whose measurement is more a matter of inference than of observation. Certainly the result will be taken as an explanation of why the Smaller Magellanic Cloud has many fewer stars than its companion satellite galaxy — its mass is smaller.

The more typical case in which the interstellar gas pressure is a function both of the rate of star formation and of the density of pre-existing stars leads to a more complicated but still simple relationship. One necessary step in the argument is to estimate the fraction of the material incorporated into new stars which remains locked up in them. They must be objects not so massive that they form supernova explosions. The result, however, is a first-order linear differential equation for the

surface density of gas as a function of time. Integration leads directly to an expression for the surface gas density as an exponentially decreasing function of time which, significantly, does not decrease to zero but, rather, to a non-zero value. In other words, even in the galaxies most productive of new stars, there will always remain a certain amount of gas that is not incorporated into stars.

Again, the agreement with observation is good. The surface density of gas as a fraction of the total surface density of a galaxy should be a straight-line linear function of the ratio of the star-formation rate to the total mass of stars, either for an entire galaxy or for part of it. In the sample of galaxies Dopita uses for the comparison, the only two galaxies that do not lie near the curve are, in a sense, exceptions that "prove the rule" — other evidence suggests that they have recently accreted gas from some extragalactic source, and are thus artificially young.

Dopita himself says it is remarkable that "such a simplistic" model should give such a good fit. He also points to what may be the most uncomfortable consequence of the argument, the short timescale for galactic evolution implied by the constants in the model, determined by the best fit of the observations with the predictions. Most galaxies, on this basis, are using up their gas content on a time scale which is short, on the order of 1,000 million years, compared with the time scale of the Universe. Dopita is again quick to point out that this difficulty has arisen previously, most notably in the work of the late B.M. Tinsley and her colleagues but specifically in work such as that of R.C. Kennicutt (see *Ap. J.* 272, 54, 1983), in which ultraviolet emission from hydrogen is used as a direct index of star formation.

On the face of things, this implies that the history of the present era of star formation in isolated disk galaxies is shorter than has previously been assumed and that, for some galaxies, the renewal of the stellar population may have only a short way to go. The puzzle is an important conundrum whose resolution is nevertheless not entirely beyond the bounds of possibility. Plainly the Dopita law does not take account of all the possibilities. But any explanation can only further complicate the difficulty of learning enough about the evolution of galaxies to rack the question of the evolution of the Universe as a whole.

John Maddox

Palaeoanthropology

Palaeobiology and age of African *Homo erectus*

from Eric Delson

FINDS of ever-older human relatives and potential ancestors have caught the public's imagination in recent years. Kenyan fossils newly described on page 788 of this issue by Brown *et al.*¹ could help to swing the pendulum of public interest back toward younger fossils belonging to species of our own genus, *Homo*. Since 1969, Richard Leakey and his colleagues have recovered human and other fossils from deposits along the eastern shore of Lake Turkana in northern Kenya. Now, a group has crossed to the west side of the lake; early work has yielded a fossil already touted in the press as a "strapping youth" whose bones will shed yet more light on human ancestry².

The new fossil has been identified as a representative of *Homo erectus*, the extinct species first named *Pithecanthropus erectus* or "Java Man" by Dubois in 1894. Skulls of many individuals of this form are now known from Java and China, mainly estimated to date between 1.2 and 0.25 Myr old^{3,4}. It is widely accepted that populations similar to *H. erectus* were directly ancestral to the earliest members of the living species *H. sapiens*, although the exact timing, geography and mode of transformation are still controversial. Unfortunately, limb bones are scarce in the Asian sites, and some of the most complete have been questioned as to their specific identification⁵.

That is the main value of the new Kenya fossil — it preserves almost all of the skeleton of a 1.6-Myr-old individual who can be sexed (as male, by pelvis shape) and aged (12 years, from tooth eruption timing). Fossils identified as *H. erectus* have been known in eastern Africa since 1960, when Louis Leakey reported a skull cap from Olduvai which matched those from Asia. Moreover, Olduvai and other sites have yielded partial limbs and pelvises attributed to *H. erectus*, but none has been associated with a well-preserved cranium, always rendering precise taxonomic identification doubtful. The West Turkana fossil (catalogued as KNM-WT 15000) preserves most of the skull and lacks only the extremities and forelimbs (the right humerus remains). The team expects to find additional portions of the skeleton with further excavation, but this degree of preservation is otherwise unknown before the Neanderthals of 40,000–100,000 years ago. By comparison, 'Lucy', the 3-Myr-old partial adult female skeleton of *Australopithecus afarensis* recovered by Johanson⁶, has a lower jaw but only bits of the skull; many fewer ribs and vertebrae; the upper and lower leg bones of only one

side of the body; but does preserve most of the two forearms and left humerus missing in WT 15000.

What will this new information tell us about how *H. erectus* lived? That is still hard to say, but one point much emphasized is the apparently great height of the individual: 1.6 m (5 ft 5 in) at death, perhaps 1.8 m (6 ft) if adult¹. Brown *et al.*¹ have moderated this claim, especially because the skull of *H. erectus* was lower than that of the modern *H. sapiens* whose bones were used to develop the height regressions; the regression estimates should consequently be reduced.

Previous estimates for the height of *H. erectus* ranged between 1.55 and nearly 1.8 m^{7,8}. They were usually based only on the length of the femur (thigh bone) and

Locations of major *Homo erectus* sites. There is controversy over whether the European and Baringo fossils should be allocated to *H. erectus* or *H. sapiens*¹².

did not consider skull height differences. Thus, the WT fossil might not have been especially large for this species to begin with. Moreover, additional cavils need to be evaluated. Modern humans show an adolescent growth spurt, especially in males. If such a spurt existed in *H. erectus*, it might have led to a height greater than the estimated 1.6 m, had the specimen lived longer.

Similarly, it is unclear that dental eruption timing then was the same as it is today; T. Bromage and C. Dean have questioned the equivalence of such timing in *Homo* and *Australopithecus* species based on counts of perikymata (developmental lines in tooth enamel)⁹. On the other hand, if most *H. erectus* individuals were rather shorter than WT 15000 (which is less likely), it is possible that this individual was atypically tall or died young because selection acted against his continued growth.

Palaeoanthropologists will probably be more interested, however, in the insights that this fossil will provide into the

patterns of growth and inter-individual differences among earlier humans. As evidenced by both dental eruption and epiphyseal fusion stages, WT 15000 was clearly juvenile. Yet Brown *et al.*¹ note that the face is larger and more massive than that of an adult *H. erectus* skull from the east side of Lake Turkana they have just described¹⁰. That skull, ER 3733, is widely accepted as female, so that its relative gracility compared with WT 15000 is not surprising (except for the age of the latter). It would be interesting to compare WT 15000 with ER 3883 (ref. 10). Some authors think the latter was a male (ref. 8) but I consider it another female and the large but stratigraphically younger Olduvai OH9 to be the male in this sexually dimorphic species.

This question leads inexorably to the two main recent foci of attention on *H. erectus*: does the species illustrate stasis or phyletic change through its 1.5 Myr span; and are the African forms really the same species as the Asian? One of the most important types of information that bear on both these questions is accurate ages for the fossils. Although Pope³ and other workers have recently argued that the oldest Asian *H. erectus* are often significantly younger than previously thought (1–1.2 Myr at most), careful re-analysis of several East African geological sequences has clarified the age of the earliest supposed members of the taxon there. Also in this issue, McDougall *et al.*¹¹ on page 792 present new data on the age of one major Turkana Basin marker horizon, the Okote Tuff complex. They report that the basal levels of this 10–15-m-thick unit date to no more than 1.64 Myr. The pumice fragments dated have a composition different from that of the enclosing tuff, suggesting reworking upwards of older pumice into the slightly younger tuff. Brown and Feibel¹² on page 794 offer further local correlations and review other dates which indicate that it is not much younger (>1.52, probably >1.6 Myr). In addition, they determined that a tuff slightly below the horizon of WT 15000 is equivalent to one of two newly defined tuffs on either side of the Lower Okote, yielding the age of 1.55–1.65 Myr for the skeleton.

These dates and others in the Early Pleistocene (through to perhaps 1.0 Myr) make it simple to begin the study of temporal variation in *H. erectus*. But as noted by Pope³, dates in Asia are still highly uncertain and younger African fossils (especially in the Maghreb) are also of questionable age. Thus, although studies such as those of Howells¹³ and Rightmire¹⁴ have suggested that variation through time is not continuous or even directional in *H. erectus*, Wolpoff¹⁵ has recently argued strongly for a gradualistic view of temporal variation and change in this species. His comparisons of 13 cranial characters across specimens grouped into three time ranges are superficially persuasive, but there are too many potential problems

for his analysis to be convincing. Several individual fossils are of questionable identification, sexual variation is not considered and the raw data are not available to see the precise effects of these factors. Equivocal age determinations and the use of time bands rather than age estimates that would permit regression analysis also disturb me. As Wolpoff notes, it has been "excruciatingly difficult to test the punctuated equilibrium model in the fossil record", not least because of methodological disagreements among researchers.

An examination of Wolpoff's list of specimens reveals that whereas East African and Indonesian fossils dominated the 'early' and 'middle' *H. erectus* time groups, the sample from Zhoukoudian, China dominates the 'late'. Some authors have recently questioned whether such comparisons are as meaningful as we might like—are the African fossils indeed members of a palaeobiological species *H. erectus* as defined from the unique characteristics of the Asian specimens defining this taxon? Howell¹⁶ reviewed the consensus position of geographical identity some years ago, providing a detailed descriptive definition without specific regard for the derived versus the conservative nature of the characters discussed. Rightmire^{17,18} has been the most vocal recent proponent of this view, arguing that several uniquely derived characters define *H. erectus* in Asia and Africa without recourse to the arbitrary use of temporal gaps or rubicons.

On the other hand, Wood¹⁹ and Andrews²⁰ argue strongly that African fossils assigned to *H. erectus* share only conservatively retained features with Asian members of that species, not any of their derived characters. Thus, they imply the need for recognition of a new species to receive African fossils possibly intermediate between *H. habilis* and *H. sapiens*. Stringer²¹ is more cautious, but agrees with

the lack of shared derived features in specimens from the two regions; he notes further that if *H. erectus* were to be defined broadly enough to include all of these fossils, most derived conditions seen in the younger Asian specimens (especially those found in China) would reject the concept of stasis in favour of definite change over time.

Palaeoanthropologists continually make the claim that more fossils will help answer pressing questions, and field workers who find them reap well-deserved rewards. If WT 15000 is any example of the quality of

material to be expected in future years from the West Turkana sequence, there will certainly be much grist for our mills. But the milling process must include careful and probing analyses of all the available fossils, matched with a willingness to test both revisionist and entrenched hypotheses and to embrace new interpretations, if we are to take full advantage of the hard-won fossils. □

Genetic diseases

Probe for muscular dystrophy

from P. Michael Conneally

DUCHENNE muscular dystrophy (DMD) is probably the most common X-linked disorder in man, affecting one in 4,000 males, the disease being transmitted by carrier females. Sisters of affected boys have a 50 per cent risk of being carriers, but there has been no reliable test for prenatal diagnosis or for carrier females, although serum creatine kinase levels are elevated in approximately 70 per cent of carriers¹. The locus for DMD is in the middle of the short arm of the X chromosome (Xp21) and two DNA probes that flank the locus have been reported within the last two years², but unfortunately they are quite far away. Elsewhere in this issue Monaco *et al.*³ describe the successful cloning of a DNA fragment that detects a deletion which is in or very near the DMD gene. This is a major breakthrough that forms the basis for much more accurate detection of females carrying the gene and for prenatal diagnosis, and that will also help us to an understanding of the aetiology of this lethal disease.

About 600 males affected by DMD are born annually in the United States alone. It is a progressive muscle-wasting disease with onset before the fifth birthday; victims are confined to wheelchairs by their early teens and usually die before they reach their early twenties. In families with one affected boy, 50 per cent of his sisters are likely to carry the gene, so about the time the affected boy dies, his sister may be giving birth to another affected boy. The new probes will mean that accurate prenatal diagnosis and carrier detection will now be available for families with affected children, and so should lead to a substantial decrease in the burden the disease places both on families and health services.

The method that Monaco *et al.* have used, which is reported in detail in a separate publication⁴, involves a very clever technique that can also be used for a number of other genetic disorders. The method allows the cloning of DNA missing from patients homozygous (or

hemizygous in the case of X-linked traits) for a chromosomal deletion. The principal of the technique is to hybridize excess DNA from the patient with the deletion to DNA from normal humans: the DNA that fails to hybridize is consequently enriched with sequences from the region of the deletion. As an extra precaution, in the case reported here, the DNA from a boy with DMD (and other problems, like retinitis pigmentosa) and a small deletion in the short arm of his X chromosome was hybridized to DNA from cells with an excess (five) of normal X chromosomes. This method is likely to be generally useful in cloning DNA containing the affected gene in specific genetic disorders involving chromosome deletions or translocations. In the past few years, it has been possible to go from genomic DNA libraries to chromosome-specific libraries and in many cases now to site-specific probes. The approach of cloning DNA from chromosomal deletions should accelerate the tedious task of finding the gene responsible for a genetic disorder, as it greatly narrows down the set of sequences from which the gene has to be isolated.

Now, Monaco *et al.*³ describe how seven of these probes from the region deleted in one DMD patient were used to check for deletions in other DMD patients and also to do linkage analyses. Five of 57 males with DMD were found to have deletions, each missing at least 38 kilobases of genomic DNA. Two subclones detect restriction fragment length polymorphisms, which can be used to identify particular regions of DNA (for an explanation of this technique, see ref. 5). These subclones were used in a linkage study, showing that the clones represent DNA very closely linked to the DMD locus, so they can be used as a marker for the gene. It is interesting that nine per cent of the mutations at the DMD locus are deletions. In two other X-linked disorders, Lesch-Nyhan syndrome and ornithine transcarbamylase deficiency, deletions have been found in 18 and 7% of cases respectively^{6,7}.

DMD is a genetic lethal because affected males do not live to reproduce. As the frequency of the gene will be twice as high in females as in males, one-third of the DMD genes are lost each generation. A similar number of new mutations arise to take their place. Thus, if male and female mutation rates are equal, one third of all DMD cases should be new mutations. There is quite a lot of controversy over this estimate but these probes should now enable us to resolve the dispute, as well as determine the relative mutation rates in the sexes. The most exciting aspect of these findings is that in the very near

future the DMD gene should be cloned and transgenic mice produced. These are major steps in determining the aetiology of DMD, which will in turn lead to fundamental insights into the basic mechanisms of this neuromuscular disease. □

Immunology

Are peptides good antigens?

from G. Ada and J. J. Skehel

It is generally considered that most antibodies elicited after immunization with a protein in its native conformation will react well with the native molecule, but that only a minority will react with the denatured protein, with linear peptides derived from it or with synthetic peptide analogues. Initially, these conclusions came from studies (reviewed by M. J. Crumpton, ICRF) of the antigenicity of proteins such as myoglobin and of tobacco mosaic virus (TMV), in which it was also observed that antibodies to modified proteins on binding to native molecules caused changes in their conformation — for example, the binding of anti-apomyoglobin to myoglobin resulted in the release of the haem prosthetic group. Similarly, when protein fragments or synthetic peptides were used as immunogens, the resulting antibodies reacted poorly with the parent molecules. In the past few years the use of synthetic peptides as antigens has been extensively documented, and a Ciba Foundation Symposium was recently convened* to discuss advances in our understanding of the antigenicity of synthetic peptides and of their usefulness as biological reagents and as components of future vaccines.

Evidence in favour of the importance of segmental mobility of TMV protein in antibody recognition was reviewed by A. Klug (MRC, Cambridge). Seven continuous epitopes in the TMV protein have been located to regions in the molecule which correspond to sequences with high local mobility, as shown by X-ray crystallography. Such observations suggest that the local mobility of the polypeptide chain facilitate interaction of antibodies with the protein antigen, and that antibodies to these regions of high mobility react with peptide analogue because the peptides in solution can assume the conformation of the mobile segments. If, however,

peptides longer than eight residues are used to assign regions of antigenicity, additional epitopes may be found, corresponding to more structured regions of the molecule, including α -helices.

The molecular basis of the antigenicity of synthetic peptides was also considered by R. A. Lerner (Scripps Clinic) in a nuclear magnetic resonance study of the conformation of a peptide from influenza haemagglutinin. In solution the nine-residue peptide was found to contain a type II β -turn stabilized by a hydrogen bond between the carbonyl of the first residue and the amide group of the fourth, a conformation different from that which the peptide assumes in the native molecule. The possible antigenic significance of such a structure may be revealed by analysis of the structure of peptide-antibody complexes that are available.

As a contribution to the study of the degree of protein flexibility involved in antigen-antibody reactions, A. B. Edmundson (University of Utah) reported a study by X-ray crystallography of the interaction between a number of synthetic peptides and the binding site in an immunoglobulin light-chain dimer. *N*-formylated peptide antigens assumed shapes which conformed to the space available for binding in the main cavity of the site. The conformation of the binding site also changed to improve structural complementarity with the peptide ligand. Among the adjustments noted were rotations and translations of aromatic side-chains and expansion of the binding cavity by movement of the first, second and third hypervariable loops.

Several contributions dealt with practical aspects of the production of anti-peptide antibodies and peptide synthesis. PPD (purified protein derivative of tuberculin) reacts well with T cells but poorly with B cells. Coupling PPD to peptides enhances anti-peptide antibody production in animals pre-sensitized with BCG (P. J. Lachmann, MRC, Cambridge).

When inoculated into BCG-sensitized rats, PPD-peptide conjugates cause delayed-type hypersensitivity reactions which facilitate retention of the complex at the site of injection and possibly contribute to enhanced antibody production. M. Sela (Weizmann Institute) reported that covalent attachment of muramyl dipeptide to a synthetic poly-DL-alanine-diphtheria toxoid octapeptide conjugate greatly increases its immunogenicity. Immunity to cholera toxin can be elicited either by a polymerized peptide from the toxin or by peptide conjugated to a lipid moiety such as the dipalmityl lysine group. M. Geysen (Commonwealth Serum Laboratories) summarized a procedure for the rapid synthesis on a solid support of a large number of peptides and its application in a study of a putative discontinuous epitope of foot-and-mouth disease virus, the main antigen determinants of which are on the VP1 protein. A monoclonal antibody against the epitope which neutralizes virus infectivity but does not react with isolated VP1 polypeptides or with synthetic hexapeptides covering the complete VP1 amino-acid sequence was used as template. Peptides of increasing length were synthesized and assayed for antibody binding after addition of each residue, some of which were β -alanines to allow structural flexibility. Finally, an octapeptide that bound to the antibody to high titre was obtained.

Two papers were presented on the antigenicity of peptides corresponding to the repeat sequences which occur in many malaria antigens. V. Nussenzweig (New York University Medical Center) described studies of the species-specific circumsporozoite protein (CSP) in which a single epitope has been identified for all monoclonal antibodies. A dodecapeptide containing three four-residue repeats conjugated to diphtheria toxoid induces the formation of antibodies which react with both CSP and the immunizing peptide and which, in an *in vitro* system, is 90 per cent effective in preventing infection. Such preparations are expected to form the basis of an antimalarial vaccine. R. F. Anders (Walter and Eliza Hall Institute) reported on two antigens, S and RESA, isolated from the merozoite stage of *Plasmodium* infections. Peptides equivalent to portions of the repeat sequences of the S-antigen, which is released on schizont rupture, have been used to show that anti-S antibodies present in sera from infected individuals are specific for the repeat sequences. At present, such antibodies are not implicated in protection from malaria infection. RESA, the ring erythrocyte surface antigen, is inserted into the erythrocyte membrane at the time of merozoite invasion. It contains blocks of related but different repeat sequences; peptides equivalent to these repeats elicit cross-reacting and repeat-specific antibodies. The biological significance of these findings was discussed, particularly

* 'Synthetic Peptides as Antigens', London, 4-6 June 1983. The proceedings will be published under the title *Synthetic Peptides as Antigens* by Pitman Publishing, London, in February 1986.

in relation to the possibility that such cross-reacting antigens produced at different stages in the life cycle of the parasite may modify the host immune response to the parasite's advantage.

V.C. Stevens (Ohio State University) reported the use of a 37-amino-acid synthetic peptide corresponding to the carboxy-terminus of the human placental hormone, chorionic gonadotropin (hCG), as a component of a birth control vaccine. Since this sequence is not shared by pituitary hormones of similar structure, its use as an iso-immunogen is considered acceptable. The length of the peptide, which appears to contain type II β -turns in solution, is critical for optimum inhibition of biological activity. When conjugated to diphtheria toxoid and administered to female baboons in a squalene-water emulsion with muramyl dipeptide, the peptide prevents 95 per cent of pregnancies; in due course fertility is regained.

Two presentations provided examples of the use of anti-peptide antibodies as experimental reagents. In an analysis of the site on human IgG responsible for the production of auto-antibodies (rheumatoid factor), a peptide analogous to the glycosylated region in the $\gamma 1$ -domain has been found to be the most active in eliciting the autoimmune response (D.R. Stanworth, Birmingham University). Differences in the extent of glycosylation at this site may contribute to its autorecognition. Experiments were also described on the use of ϵ -chain peptides to elicit antibodies which might modulate IgE-mediated hypersensitivity in rats and humans. G. Evan (Ludwig Institute, Cambridge) described the use of peptides to produce monoclonal and polyclonal anti-

bodies against the product of the *myc* gene and their use to identify the intact *c-myc* phosphoprotein in normal and transformed cells. They have also been used to localize the protein in cell nuclei in culture and in tumour masses by whole-body detection of ^{125}I -labelled antibodies.

Considerable enthusiasm has been generated for the use of peptides as components of vaccines, and the results obtained with CG and malarial CSP peptide analogues have gone some way to support this. In both cases, the size of the immunizing peptide is important and this may indicate a requirement for more than one sequence in a peptide to be recognized, or that peptides of these sizes more readily assume conformations required for immunogenicity. But it also became clear that many synthetic peptides do not induce antibodies that react with the native parent protein, arguing against the general applicability of peptides in vaccine production at this stage. Such observations also have implications for the interpretation of basic studies of protein antigenicity in which the definition of antigenicity is simply based on the characteristics of the assay systems employed, which often involve the use of peptides or modified proteins as antigens. As a consequence the criteria which have been singly deduced from these studies to be indicative of antigenic regions in native proteins are unlikely to be universally applicable. $\square$

Computers

More parallel than others

from D. Parkinson

PARALLELISM in computers takes many forms. Single operations use parallelism to enhance performance by, for example, fetching all 'bits' of a word simultaneously from memory or by using parallel circuitry to speed up operations such as addition or subtraction. Single-operation (bit-parallel) has been common since the earliest computers, when manufacturers began to use 'pipelined' operations to speed up the execution of streams of instructions. Pipelining is the computer's equivalent of the industrial production line, in which a complex operation is split into several sub-tasks and the operands are fed through a series of specialized facilities that perform these sub-tasks. It is a well-established procedure in computer design and usage, but the invention of the vector processor and creation of general purpose multiple-processor systems have awakened new interest in the possibilities

of parallel processing.

As a trivial example, imagine the following basic operations on a stream of instructions: fetch the instruction from memory; decode the instruction; obey the instruction. A three-stage pipeline could be constructed that would allow all three instructions to be analysed simultaneously. The first would be obeyed while the next is being decoded and the third is being fetched, the process being three times faster than a non-pipelined system.

The pipelining principle is also well-established for building high-performance signal or process-control systems. Here the tasks in the pipeline might be allocated to separate special-purpose boxes for performing operations such as calibration and convolution or transforms. Both these applications of pipelining are examples of parallelism, but they display parallelism at different levels of 'granularity'. The

instruction-decoding example is fine-grain parallelism where the amount of work between synchronization activities is small. The signal processing application exploits coarse-grain parallelism where large amounts of computation are carried out between synchronizations. There is, of course, nothing that prevents the operations of the coarse-grain system being implemented by systems that exploit fine-grain parallelism.

The vector processor, such as CRAY-1, CYBER-205, is a further refinement of the pipeline principle to perform repeated application of identical instructions to sets of data, the so-called vectors. If we wished to perform the operation $x(i) + z(i)$ ($i = 1 \dots N$), then increased performance is possible if the hardware can perform the instruction-decode operation only once and include all indexing operations in the pipeline. Vector processors have special facilities to perform these operations and so can provide increased performance for that range of computations which can be expressed in terms of the vector operations. The instruction-decoding base for a vector instruction is more complex than for a simple scalar instruction, so there must be minimum number of elements in the vectors before vector instructions can be faster than a set of scalar instructions. This characteristic of vector processors means that the programming or computational methods for full exploitation of a vector processor can be very different from those used in the simple early computers.

Alongside the development of vector processors, multiple-processor systems have been developed consisting of many interconnected computers, all of which can be used to solve a given task. The earliest system was the ILLIAC IV, intended to be a 256-processor system but only one quarter of the machine was ever built. Although great computational power could be achieved on parts of problems, many problems suffered large-scale degradations because of inadequate facilities for moving data amongst the processors.

The attractions of obtaining increased performance by using many computers is obvious, hence the many attempts to develop such systems. To date, the most successful of these have been two designs in the United Kingdom — the DAP from International Computers Ltd and the CLIP IV from University College, London. Six DAPs have been installed since 1980, each with 4,096 processors in a 64×64 array. They are used in a wide range of general-purpose computations. The CLIP is available commercially in various configurations of 32×32 , 32×64 and 64×64 processors.

The processor arrays are specialized in the sense that they all respond to a single instruction stream broadcast from a master processor. Hence, if one processor is performing an addition operation, all the

other processors also perform an addition operation (which might be a dummy). Although this 'lock-step' characteristic appears very restrictive, most user experience has shown that such lock-step processor arrays are highly flexible. Processor arrays and vector processors are often called single instruction multiple datastream (SIMD) processors, as a single instruction produces many results.

It is generally accepted that a collection of processors that did not have to work in lock-step fashion would be more flexible than a SIMD system. Therefore, there are many attempts to develop multiple instruction datastream (MIMD) systems, mainly as part of programmes such as fifth generation ALVEY and ESPRIT. One of the dreams of computer scientists is the ideal MIMD computer with the following properties: it supports a programming methodology that does not need to know how many computers are in the system; it can double in performance if the number

of computers is doubled; and it automatically rejects any failing computer yet continues to work.

The production of computers with these desirable properties is a major research target. Nearly every day there is a new proposal for a computer architecture system which its designers claim will meet the aims. Many one-off experimental systems exist in universities, but none seem to have gained external acceptance. There is, perhaps, an analogy between the programmes to build an ideal MIMD system and that to build an operational fusion power generation plant. Everyone agrees that it would be a good thing to do, lots of money is being thrown at the problem, but nobody has yet shown that it can be done. However, interesting things are happening—watch this space! □

Quantum fluid dynamics

Instabilities at absolute zero

from K. W. Schwarz

ILLUSTRATIONS of flow around a sphere are a seemingly essential part of every textbook on fluid dynamics. At low velocities, the fluid is seen to make its way smoothly past the sphere. The nonlinear nature of flow phenomena, however, becomes spectacularly evident at higher velocities, with the appearance of a vortex ring (similar to a smoke ring) in the wake of the sphere. At still higher velocities, the ring is intermittently shed into the fluid, leading eventually to completely turbulent flow behind the sphere. McClintock, Bowley and colleagues, on page 797 of this issue¹, examine the quantum mechanical analogue of this venerable problem. In the latest in a series of remarkably elegant experiments, using electrons injected into liquid helium to form bubbles, they find, unexpectedly, that when a bubble is pulled very quickly through the fluid a stream of microscopic quantized vortex rings is generated. The similarity to classical flow around a sphere is both striking and aesthetically satisfying, and it should help us understand better the appearance of instabilities in quantum fluids, such as ⁴He.

Helium-4 remains liquid down to absolute zero. In this limit, it obeys the laws of quantum mechanics, which operate on a macroscopic scale under such conditions. The rules governing the motion of this 'superfluid' are therefore very different from those of classical fluid dynamics, and are still only imperfectly understood. Two kinds of excitations are known to be possible in superfluid ⁴He: vibrational excitations, somewhat analogous to sound waves, and flow excitations in the form of quantized vortex lines. The latter are

essentially localized microscopic whirlpools, the fluid circulating rapidly around a central line about 0.1 nm thick, with the velocity dropping off away from the core. Such quantized vortex lines can exist as arbitrarily configured continuous curves in the fluid, either as segments which terminate on boundaries, or as free-floating loops and rings. Once there, they obey the laws of classical fluid dynamics. What is not understood is how they arise in the first place as an instability of quantum flow. Thus it is of the utmost interest to study how 'superflow' past a simple object such as a sphere becomes unstable.

To carry out their experiments the authors make use of the well-established fact that an excess electron injected into liquid helium forms a well-defined spherical bubble with a radius of about 1.5 nm. Such electron bubbles can be accelerated through the superfluid by applying an electric field, and their motion can be detected as a current. Since the movement of such a structure displaces thousands of helium atoms, the flow around it can be thought of as macroscopic. Yet, the dimensions of the bubbles are so small that any quantum instability that occurs can be expected to involve individual excitations of the kind described above. Earlier investigations^{2,3} had in fact established that, depending on the pressure, a rapidly moving electron bubble will either create a single vortex ring to which it remains attached, or it will emit a continuous stream of vibrational excitations. Thus, depending on circumstances, instability with respect to either type of possible excitation was known to occur.

Although they have also made major contributions to our knowledge of the vibrational-excitation instability⁴, McClintock, Bowley and coworkers have more recently concentrated on the situation where the flow around the bubble becomes unstable leading to the creation of quantized vortex rings, a situation that appears to more closely resemble the classical problem. By doing experiments in isotopically pure ⁴He at sufficiently low temperatures, the scattering of thermal vibrations by the moving bubble becomes rare, so they have been able to study the problem in its purest form. That is, they can look at what happens as the bubble is pulled more and more forcefully through the zero-temperature superfluid. They find that initially the bubble accelerates exactly as would a sphere moving through an ideally frictionless classical fluid⁵. When a critical velocity is reached, a quantized vortex ring attached to the sphere is created. The unexpected result of their latest experiment¹ is that, when a very large field is applied to pull the bubble through the fluid very quickly, a continuous stream of vortex rings is emitted by the moving bubble.

These latest results promise to lead to new insights into the nature of quantized-vortex creation. At present, not much is understood theoretically about this process. An early calculation by Schwarz and Jang⁶ demonstrated that the critical velocity is determined by the instantaneous application of energy and momentum conservation, implying that the vortex appears as the result of a sudden quantum transition. This point of view appears to be generally accepted today and much more ambitious models have recently been proposed^{7,8}. The subject, however, is controversial, and in particular the very basic issue of defining the configuration in which the quantized vortex first appears remains under debate. By comparing experimental results of the kind reported here against hydrodynamic calculations using various starting geometries for the vortices, it may now be possible to determine this initial configuration. Prospects for attaining this milestone seem encouraging, although a great deal more theoretical and experimental effort will be required. □

Cytoskeleton

Splitting hairs and other intermediate filaments

from Peter M. Steinert and Alasdair C. Steven

EVEN though keratinized tissues rich in intermediate filaments were possibly the first biological substances to be probed by X-ray diffraction techniques (ref. 1), solving their structure remains a plum to be picked. These filaments, 10–15 nm in diameter, form one of the three major cytoskeletal networks in eukaryotic cells. They differ from the other two, F-actin and microtubules, in several important respects. For example, unlike the other two, intermediate filaments are composed of α -helix rich fibrous protein subunits, and their distributions and state of assembly in cells seem to be governed by quite different rules. Their precise function(s) in cells remain obscure, so an understanding of the details of their structure is an important first step in elucidating their cellular functions. A flurry of recent papers describing the amino-acid sequences of around 30 subunits suggests that the broad principles of intermediate filament structure will soon be understood.

All the filaments have been found to contain a central α -helical 'rod' domain of conserved secondary structure, flanked by end domains of variable size and chemical character. The rod domains possess four discrete segments of precisely conserved size that can form coiled-coils, termed 1A, 1B, 2A and 2B, interspersed by regions that cannot form coiled-coils (*a* in figure). The rod domain sequences conform to several distinct types: the 10–15 acidic keratins (Type I); the 10–15 neutral-basic keratins (Type II); vimentin, desmin and glial fibrillary acidic protein (Type III); and neurofilament proteins (possibly comprising at least one other type²). Convincing evidence now shows that pairs of subunits align in parallel and in axial register to form two-chain coiled-coil molecules (*b* in figure)² but it is not known how these molecules combine to generate higher orders of intermediate filament structure. Observations using the scanning transmission electron microscope³ suggest that most filaments,

irrespective of their subunit composition, contain about 16 molecules in cross-section. These and other data have also contributed to the emerging concept that the rod domains form the cores of intermediate filaments and that the interactions of these domains are primarily responsible for defining filament structure. The end domains are located on the periphery of this core and define the functions of different filaments in cells^{2,3}.

At the immediately supramolecular level, several lines of evidence invoke a dimeric association of molecules in a four-chain oligomeric complex^{4,5}. It is plausible that such an association should be based

particles, but interpreted them not as models 3–5, but as staggered pairs of four-chain complexes. Again, the complexes might be parallel or antiparallel, but their neighbouring constituent two-chain molecules should nevertheless comply with models shown in *c*.

The ingenuity of these experiments notwithstanding, their apparent incompatibility poses a problem: which data are correct? Or is every investigator right? Assuming that keratin and Type III intermediate filaments do share a common structure, there may be at least one way to reconcile this paradox. Conceivably, there may be multiple modes of intermolecular associations in fully assembled filaments, so that more than one of the models in *c* may be applicable. Then, disassembly or reassembly of intermediate filaments under conditions of varying salt or pH might selectively weaken different sets of interactions and split the same structure into different four-chain complexes. This idea could be tested by the

on alignment of the long (1B and 2B) coiled-coil segments²; if so, there are essentially only five possibilities (*c* in figure). Models 1 and 2 predict the segments to be about 48 nm long and the others predict them to be about 70 nm.

Two recent studies have cast some light on these alternatives. Using quick-freeze deep-etching electron microscope techniques, Ip *et al.*⁶ have characterized a 48 nm particle as the tetrameric building block for vimentin. This is consistent with models 1 or 2, but cannot distinguish between them as the differences depend on the polarity of the molecules. But, by using a monoclonal antibody against region 2B of the desmin rod, Geisler *et al.*⁷ seem to have answered this question. They found dumbbell-shaped structures averaging 48 nm in length, denoting antibody binding at both ends of a similar tetrameric desmin complex and compatible only with model 2. However, in other studies on isolated α -helix-enriched particles obtained from proteolysed keratin intermediate filaments, 1B tetramer particles were obtained^{8,9} which could only have derived from models 1 or 4 and not from model 2. Under modified salt conditions, Ip *et al.*⁶ visualized larger 70-nm-long vimentin

experimental approaches described here.

Taken together, recent reports make it likely that neighbouring pairs of two-chain coiled-coil molecules in intermediate filaments are antiparallel, meaning that the filaments are non-polar structures. Thus, unlike the other mainstays of the cytoskeleton, F-actin and microtubules, intermediate filaments don't know whether they are coming or going. Further developments in this rapidly evolving field hopefully will extricate researchers from a similar dilemma. □

100 Years Ago

MANY interesting excursions have been arranged for the Aberdeen meeting of the British Association. One of them will, of course, be to the great granite quarries in the neighbourhood of Aberdeen. Her Majesty has invited 150 of the members to Balmoral, where they will be shown over the grounds and have lunch. It is not to be expected that the Queen will personally receive all the members, though it is possible that a few representative men of science may be presented to Her Majesty.

Plate tectonics

Room at the top of the world

from J. Tuzo Wilson

BENEATH the ice the Arctic Basin is vast, poorly known and difficult to study. Perhaps the only thing that can be said with certainty is that its geology and geophysics are complex. This lack of information has enabled some scientists to claim that there is no room in the Arctic for the global motions of the Earth's crust required by plate tectonic theory. This raises a dilemma for supporters of that theory, but fortunately a broader view and new data from two expeditions (Weber, J. R. & Sweeney, J. F. *J. geophys. Res.* **90**, 663, 1985; Sweeney, J. R. *Geos* **13**, 8, 1984) suggest alternative solutions.

One aspect of the problem is that most mid-ocean ridges (where new oceanic crust is created) are aligned roughly north-south, spreading out from a ring through the southern oceans (Fig. 1a). This rough symmetry of the mid-ocean ridge system is a relic of the break-up of Gondwana which commenced about 250 Myr ago (Fig. 1b). At that time, the southern continents were clustered round Antarctica. But since the girth of the globe increases towards the Equator, the continents were forced to separate as they moved slowly northwards. This spreading apart of those continents which once surrounded Antarctica like blocks in an arch explains why they all have triangular or trapezoidal shapes narrowing to the south. Once across the Equator, one would expect the continents to be forced together again and to override mid-ocean ridges, just as North America has overridden the East Pacific Rise. If forced to converge in Arctic regions, there would not be enough space

Fig. 1 Cartoon maps of the world as it is now (a) and as it was 200 Myr ago, before the break-up of Gondwana (b). The spreading centre which formed a ring around Antarctica has expanded greatly, driving the continents northwards. Today, a subduction zone decouples the movements of the southern and northern continents.

for them or to permit any fresh spreading.

As if not content with the rate of progress towards such a continental crash, dozens of fragments like those of Baja and western California have been moving polewards up the coast of North America. This has created a complex of terranes in Alaska and British Columbia, which led P. B. Jones (*Can. Soc. Petrol. Geol.* **80**, 83, 1982) to suggest that all of Alaska is moving towards the Arctic Basin. But that view is at odds with new data emerging from Canadian expeditions which indicate extension rather than compression in the Arctic. The impasse can be avoided if account is taken of the globe-encircling zone of subduction and continental collision which separates the Gondwana continents from the others. This zone extends from the Mid-Atlantic Ridge near the Azores eastwards along the active mountain and island arcs of southern Eurasia to Indonesia and thence around the rim of the North Pacific Ocean to Central America and the Caribbean (Fig. 1a). The sliver of western California which is now moving north lies on the southern side of this zone. This suggests that rather than pushing into the Arctic Basin, the fragments now forming Alaska could have been accreted at a subduction zone which 'insulated' the Arctic.

An important question in plate tectonics is whether ocean basins are passively pulled apart at mid-ocean ridges, or whether the spreading is driven actively by forces originating in the mantle. D. I. Gough (*Nature* **311**, 428, 1984) has shown that a whole variety of phenomena, ranging from topography to *in situ* stress measurements indicate that active spreading is continuing beneath the western United States in the region which has overridden the East Pacific Rise. This supports the latter possibility, which is lent further credence from recent discoveries in the Arctic Basin.

The chief conclusion from the LOREX (Lomonosov Ridge Expedition) expedition, reported by Weber and Sweeney, is that the Lomonosov Ridge (Fig. 2) is a remarkably uniform, steep-sided, flat-topped feature with at least one kilometre of flat-lying sedimentary layers underlain by a root, extending perhaps to 25 km depth within which the density increases downwards from 2.5 to 2.95 g cm⁻³. This lends support to the widely accepted view that the ridge is a block-faulted fragment of continental margin detached from Siberia 53 Myr ago by normal seafloor spreading at the Nansen-Gakkel Ridge in the Nansen Basin.

Weber and Sweeney suggest from limited data that the Alpha Ridge may once

have been joined to the Lomonosov Ridge and have had a similar origin, but that extension, including faulting, and injection of much mafic rock (as in the Lord Howe Rise north-east of New Zealand) can explain its thinner crust and magnetic lineations. They also admit that it could be a plateau of thick oceanic crust. Other results indicate that the Canadian end of the Makarov Basin is a faulted trough 25–60 km wide produced by extension "other than typical seafloor-spreading". It is partly filled with flat-lying sediments and has a crust 14 km thick.

Preliminary analysis of data gathered on a later expedition — CESAR (Canadian Expedition to Study the Alpha Rise) — reported by Sweeney, strengthens the idea that the Canada Basin also opened by

Fig. 2. Sea floor geography beneath the North Pole, showing the main tectonic features.

spreading when a crustal block, comprising northern Alaska and northwestern Siberia, which had lain against the Canadian Arctic Islands, rotated to its present position. Imprecise age determinations suggest that continental break-up began some time between 131 and 113 Myr ago and that new sea floor was formed from 118 to 79 Myr ago. H. R. Jackson, D. Forsyth, & G. L. Johnson (personal communication) support these views and show that the thickness and seismic velocities beneath the Alpha Ridge correspond to those of the thickened oceanic crust beneath other large oceanic plateaus, including the Manihiki, Shatsky and Hess rises. All these features formed during the magnetically quiet period in the late Cretaceous, probably at complex plate junctions.

The inescapable conclusion to be drawn from these studies is that despite the expectation from global tectonics that the region would be under compression, abundant spreading has in fact occurred. Together with the evidence for active spreading under the western United States, the new data from the North Pole support the view that spreading is caused by powerful forces within the mantle. □

the highly successful series**

NEW COMPREHENSIVE BIOCHEMISTRY

General editors: A. Neuberger and L.L.M. van Deenen

VOLUME 12

Sterols and Bile Acids

edited by J. Sjövall and H. Danielsson

This volume contains authoritative reviews by renowned experts in the fields of biosynthesis, metabolism and functions of sterols and bile acids. The fourteen chapters cover biosynthetic pathways, in vertebrates, invertebrates and plants, regulatory mechanisms and interactions with proteins. Further, absorption of lipids and physicochemical properties of sterols and bile acids are reviewed.

VOLUME 11

Modern Physical Methods in Biochemistry Part A

*edited by A. Neuberger and
L.L.M. Van Deenen*

The progress which has been made in the biological sciences, particularly in biochemistry, over the last 20 years has been caused to a large extent by the development of sophisticated physical methods and their application to biological problems. Our knowledge of the structure and especially the conformation of protein and nucleic acids has been helped greatly by the use of mass spectrometry and a variety of optical methods, such as circular dichroism and the extension of optical rotary dispersion to low wavelengths. The use of electron spin resonance has been of special use in our understanding of oxidation and reduction processes, and also has been helpful in other problems affecting the structure of important organic molecules. The use of nuclear magnetic resonance has been another very important development in biological sciences. It is even being used to an increasing

extent in physiological investigations, and its application to clinical medicine is likely to be of considerable benefit. The use of X-ray crystallography goes back to the 1930s, but in recent years the techniques have been refined so that resolution has been increased to a significant extent. This volume describes the techniques used in a manner which is intelligible to the non-expert, and to describe at least some of the applications of these techniques to important biological problems. The present book will be followed by a second dealing with a variety of other physical techniques. It would be quite impossible to deal with all physical methods which will be used over the next 5 or 10 years, but we hope to cover most of the major techniques which will be applied in solving important biological problems.

VOLUME 10

Glycolipids

edited by H. Wiegandt

Knowledge in the field of glycolipids has rapidly expanded in recent years due to the advancement of specialised techniques. This work is a comprehensive reference source and the first book to deal with all three major groups of glycolipids: the sphingolipids, including their sialic acid containing components, the gangliosides; the glycerol- and isoprenol-glycolipids.

It was the intention of the author not only to review the most recent advances of glycolipids but also to provide an introduction for the interested non-specialist reader. All scientific institutions, including those affiliated to the interested industries (pharmaceutical) and hospitals, will find this work an invaluable practical guide and reference.

Bioenergetics

edited by L. ERNSTER

Bioenergetics is the study of energy transformations in living matter. It is now well established that the cell is the smallest biological entity capable of handling energy. Every living cell has the ability, by means of suitable catalysts, to derive energy from its environment, to convert it into a biologically useful form, and to utilize it for driving life processes that require energy. In recent years, research in bioenergetics has increasingly been focused on the first two of these three aspects, i.e., the reactions involved in the capture and conversion of energy by living cells, in particular those taking place in the energy-transducing membranes of mitochondria, chloroplasts and bacteria. This area, often referred to as membrane bioenergetics, is the main topic of this volume.

The fall of Nikolai Vavilov

J.R.S. Fincham

The Vavilov Affair. By Mark Popovsky. *Archon/Clio:1985**. Pp.216. \$22.50, £21.40.

This book, by a former Soviet writer now resident in the United States, traces the career, downfall and destruction of the most famous Soviet biologist of the inter-war period. N.I. Vavilov was the son of a wealthy self-made businessman and one of two brothers, the other a physicist, who both became Academicians.

As a young man Vavilov spent two years (1912–1914) in England under the tutelage of the geneticist William Bateson and the plant breeder Rowland Biffen. At the time of the 1917 revolution, when he was 30, he had just been appointed to a professorial chair in Saratov. In 1920 he left Saratov to become head of the Bureau of Applied Biology in Petrograd and five years later was appointed Director of the new All-Union Institute of Applied Biology (in effect, Plant Breeding), the foundation of which, according to Popovsky, was a consequence of Lenin's having read an American book on the great potential of plant breeding. This Institute became the headquarters, and Vavilov the chief, of a great network of research institutes and experimental stations employing, it is said, as many as 20,000 people. With these resources at his disposal, Vavilov devoted his great energies to organizing and leading plant-hunting expeditions to many parts of the world and established very extensive collections of wild relatives of cultivated plants for investigation in his own institutes. He also wrote indefatigably on plant geography, the history of agriculture and origins of cultivated plants, and the theory and practice of plant breeding, with emphasis on the use of wild species as sources of such valuable traits as disease resistance.

From the early 1930s, Vavilov's enterprises came under increasing challenge from the ambitious T.D. Lysenko whose position, which may be summed up as Lamarckist, anti-élitist and ignorant, attracted increasing political support. In the Soviet climate of the time, criticism of Vavilov's science as academic and insufficiently practical slipped easily into accusations of philosophical and ideological error and eventually of treason. Vavilov was arrested while on a collecting expedition in August 1940, and sentenced to death as a saboteur and spy in July 1941, but was not in fact executed; he died in the prison hospital in Saratov in January 1943.

Mark Popovsky started his research into Vavilov's life in 1964. At that time the process of posthumous rehabilitation was already well under way, and Popovsky was able to gain access to a number of different sources. For the period up to 1940 he cites mainly the archives of the Lenin Academy of Agricultural Sciences (from the Presidency of which Vavilov was displaced by Lysenko in 1933) and of Vavilov's old Institute. He also interviewed a considerable number of Vavilov's former colleagues. In 1966 he published a narrative based on this information under the title 'A Thousand Days of Academician Vavilov' in a Soviet magazine. This account was cited (with some critical amendment) by Zhores Medvedev in his definitive book *The Rise and Fall of T.D. Lysenko*, published in I.M. Lerner's English translation in 1969.

The most novel part of the present book is based on the massive police files on Vavilov to which Popovsky was rather amazingly granted access. These contained a full record of Vavilov's lengthy interrogation and brief trial, as well as a large collection of much earlier material — letters from Vavilov's opponents and from police informers — and some later letters from Vavilov appealing for clemency. Popovsky describes his daily visits to the procurator general's office in Moscow, where he sat making notes under the eye of an invigilator who allowed him to see more than he was supposed to, assuming, Popovsky conjectures, that a person of such affrontery must be acting on higher

authority. The official purpose of this exercise is not made clear. There was obviously no intention of allowing Popovsky to publicize his findings. Indeed, he subsequently ran into increasingly bad trouble with the authorities for disclosures. In 1977 he was allowed to emigrate, and managed to smuggle some of his notes out with him, much of the rest having already been sent abroad.

So what do we learn from this new evidence? We obtain some insight into the material — a mixture of bigotry and personal malice — from which the charges against Vavilov were fabricated. We also learn, not too surprisingly, that, under pressure of prolonged interrogation, Vavilov was prepared to compromise. He admitted the charges of deliberately leading Soviet plant research along wrong paths and was prepared to incriminate others (already dead) as accomplices in that crime. However, he continued to deny that he had been guilty of espionage. He never lost hope that, even though imprisoned, he would be allowed to resume scientific work, perhaps in the kind of institute of captive scientists described in Solzhenitsyn's *The First Circle*. It appears that in June 1942 Beria had decided to permit this, but that in the confusion of the war the plan was forgotten or countermanded. At all events, seven months later the opportunity was lost and Vavilov was dead.

In the final chapter of his book Popovsky recounts what he was able to find out as a member of a group sent to Saratov by a Commission of Investigation set up by the Soviet Academy of Sciences. This group interviewed, not very fruitfully it appears, some of the prison hospital staff who had charge of Vavilov during his last days. Popovsky devotes several pages to the cause of death, accusing the prison staff of falsely misrepresenting it as pneumonia

Before the storm — Vavilov in 1928, driving an electric plough on a station belonging to the Central Asian State University. With him is his son Oleg.

*Archon, Box 4327, 995 Sherman Avenue, Hamden, Connecticut 06514, USA. Clio Distribution Services, 55 St Thomas' Street, Oxford OX1 1JG, UK.

when it was really starvation. It hardly seems to matter much, and one supposes that it may well have been a combination of the two; the circumstances must have been conducive to both conditions.

What was Vavilov's standing as a scientist and what did he achieve? In his own time he enjoyed a considerable international reputation, demonstrated by his election as President of the 1939 (Edinburgh) International Congress of Genetics (which he was prevented from attending). This was no doubt in part a gesture of support for a fellow scientist in difficulties, but was also a recognition of his scientific stature, recognition that was reaffirmed in a special session of the 1980 (Moscow) Congress. But, tragically, much of his work was aborted. His plant collections were largely lost and most of the great books that he had planned could never be written. His most important theoretical contributions, the idea of centres of origin of cultivated plants and the Law of Homologous Variation (which may be para-

phrased by saying that related species have similar genes subject to similar kinds of mutation), hardly bulk large in today's textbooks; they have achieved the status of the valid but obvious — the fate of many good ideas in science. Vavilov's commitment to the preservation and exploitation of wild species is now widely shared, and this may well be his most important scientific legacy. But he will probably be most remembered as a victim of the perversion of science in the service of ideology and the struggle for power.

Mark Popovsky has written a most saddening and thought-provoking book. As a work of history it suffers from the defect that its most important sources cannot be checked, either by the reader or now by the author himself. But it is as good a biography of Vavilov as we are likely to get in present circumstances. □

Sweet — and sour

John Yudkin

Sweetness and Power: The Place of Sugar in Modern History. By Sidney W. Mintz. Viking: 1985. Pp.274. \$20, £14.95.

DURING the past three centuries, the quantity of sugar consumed in Britain has risen from an average per person of 4 lb a year to the present 100 lb, so that it now constitutes a greater proportion of the diet than does any other food, or indeed a greater proportion than that contributed by all the meat, poultry, eggs and fish that we eat. There have been similar increases in sugar consumption in other industrialized countries, although they began more recently. By itself, sugar would not be consumed in very great quantities, and then only in solution. But in combination its wide range of properties make it suitable for use in sweetmeats and fruit preservation, for enhancing the taste of vegetables and meats, for making jam and ice cream, and for making intricately sculptured designs ranging from the icing on cakes to large sculptures of figures and buildings.

The cultivation of sugar cane began in the Far East about 500 bc and during the seventeenth and eighteenth centuries in particular spread rapidly to many parts of the world where the climate is tropical or sub-tropical. Because it needs intensive labour, the growing of cane as a crop resulted in a massive movement of populations and was responsible for the resettling of great numbers of Africans in the Caribbean and central and north America, and for the extinction of the indigenous population of several of the Caribbean islands. It is difficult to exaggerate the demographic, cultural, social and economic effects of the importation of black slaves to the Western hemisphere. Among other things, it was responsible for the dependence of the sugar-growing countries on what virtually became a monoculture, and thus for the distortion of local agriculture, local food supplies and local patterns of nutritional deficiencies.

What was the cause of the enormous increase of sugar growing in these countries and its consumption both there and in the industrial nations, beginning with Britain? In his wide-ranging account of the history of the subject, Dr Mintz mentions such factors as rapid developments in the efficiency of production of the cane and its yield of sugar, technical improvements in refining, the introduction of sugar from beet, the spread of the drinking of hot beverages — tea, coffee and chocolate — as well as the discovery of eating chocolate, and, finally, the rise in the purchasing power of individuals in the consumer nations. He also convincingly develops the theory that production and

Something in the air

James E. Lovelock

Chemistry of Atmospheres: An Introduction to the Chemistry of the Atmospheres of Earth, the Planets, and their Satellites. By Richard P. Wayne. Clarendon: 1985. Pp.361. Hbk £30, \$39.95; pbk £14.95, \$19.95.

TEXTBOOKS about the atmosphere have until now not fully reflected the new knowledge from space exploration. Just as important, they have failed to observe that the atmosphere is essentially a biological product. These earlier texts stand in science rather as does the Old Testament to a Christian; not wrong, merely unfulfilled. Richard Wayne's admirable book is definitely of the New Testament of atmospheric science.

The book is easy and enjoyable to read. It is a fine piece of craftsmanship, with a most comprehensive bibliography and index, and illustrates with clarity the interactions between the professional practice of physical chemistry and the larger domains of science and the world itself. It is especially refreshing to find illustrations taken where appropriate from sciences ranging from astronomy to zoology. Here the demarcation disputes over the territorial boundaries of science no longer imprison our imagination.

My only point of difference is over the space given and the deference shown towards that curious obsession of aeronomists — impending doom from the depletion of stratospheric ozone. We inhabit a world where the environment is threatened by carbon dioxide increase, changes in land use, acid deposition and a rise in the concentration of tropospheric

ozone. To spend more than a few words on the lesser ailment of stratospheric ozone depletion seems out of balance. I well understand why physical chemists are transported by thoughts about the stratosphere and the ozone there. Ozone is a key constituent of an important part of the atmosphere and the stratosphere is an near-ideal reactor for the study of photochemical reactions, no less than 250 of which have so far been listed. It should not be necessary to use doubtful arguments about a possible increase of skin cancer in the next century to justify such important research. This disagreement over emphasis in no way detracted from my enjoyment of the thorough discussion in the book of the intricate chemistry of real or potential pollution problems. There is also proper and decent speculation about consequences and on what more we need to know.

Recent explorations have brought the upper atmosphere down to Earth. The chapters on ionization and on the air glow nicely bring together the old and the new chemistry of this upper region of the air. And the account of extraterrestrial atmospheres describes the very different chemistry of those barren worlds and provides a contrast to that of the Earth where life has created a strange and beautiful anomaly in the Solar System.

Chemistry of Atmospheres is much more than a first-rate student text. It is also a scholarly interim report on the state of the subject as seen by a broad-minded physical chemist. Anyone with a serious interest in the atmosphere and the chemistry of the gaseous particles it carries will benefit greatly from reading Richard Wayne's book. □

James E. Lovelock is an independent scientist working at Coombe Hill, St Giles on the Heath, Launceston, Cornwall PL15 9RY, UK.

distribution of sugar powerfully affected the relationship between the wealthy and the labouring classes: "Probably no single food commodity on the world market has been subjected to so much politicking as sugar". This is a view that, in more lurid detail, is exposed by Al Imfeld in his recent book *Zucker* (unfortunately not yet translated from the German). Together with *Sweetness and Power*, these accounts serve as an illustration of the extent to which the study of this universally popular food is the province of the historian, economist, demographer, geographer, anthropologist and sociologist, as well as the clinician and scientist.

As a final attractive titbit, Dr Mintz

Enough to make you sick? Etienne Tholoni, a great French sugar baker, puts the finishing touches to a life-size chocolate nude with spun-sugar hair. She is lying on a bed of six-hundred sugar roses. (Centre de Documentation du Sucre; reproduced from *Sweetness and Power*.)

serves up a splendid dessert in which he discusses the current changes in the traditional eating patterns of industrialized societies, and the extent to which the multifarious uses of sugar play a part. The wide and increased proportion of specialized manufactured food and snacks, and the fast-food revolution, have changed when, where, what, how much and how quickly people eat, and the result is to produce what Dr Mintz calls "desocialized eating".

This is a book that can be read for its fascinating story or studied as a well-researched, scholarly and excellently documented work; it is beautifully written, with a good index, copious bibliography and extensive notes. Such a combination of qualities is a rare commodity — unlike the ubiquitous substance that is the subject of the book. □

Eating for survival in China

Brian Bertram

The Giant Pandas of Wolong. By George B. Schaller, Hu Jinchu, Pan Wenshi and Zhu Jing. University of Chicago Press: 1985. Pp.298. \$25, £23.75.

WE HAVE been waiting for years for data on giant pandas in the wild in China. A full-scale collaborative research programme in the field started there at the end of 1980; it is still continuing, but the results of the first 18 months of work have now been published.

George Schaller is renowned for his ability to obtain superb data from large wild mammals — gorillas, lions, snow leopards — under difficult conditions. With his work on giant pandas the tradition continues. As the report makes clear without emphasizing the point, pandas are exceedingly difficult creatures to study. Quite apart from the administrative, logistical and language problems involved, the animals inhabit dense bamboo forest on steep mountainsides. The climate is unlovely: "... cool and wet ... snow fell between late October and April ... on rare days when the rainclouds part and sun reaches the valley ... even when it did not rain, fog continued to swirl along slopes, everything remained sodden ...". And the quiet, shy and relatively inactive pandas cannot be seen through the bamboo if more than 10–15 metres away, and they do their best to remain further away than that. During a 16-month preparatory phase, the research team saw pandas only 39 times. Only radio-tracking makes them at all possible to study, but still not at all easy.

The team had radio-collars on six individuals, and so managed to get information from over 1,500 panda locations. In the three main data chapters they present the results. The hard-earned information is fascinating, but pandas basically are not exciting for the very good reason that their lives are largely taken up with eating bamboo (over 99 per cent of their diet). Nonetheless, the book brings out beautifully the complex and highly unusual interaction between the panda and its food supply.

Giant pandas, as carnivores in origin, have a short gut in relation to their body size and to their food needs, and they cannot break down cellulose. Digestion is inefficient, and the food passes through the gut rapidly. A 90 kg panda has to take in between 12 and 38 kg of bamboo per day; the amounts vary with the season, and depend on whether the panda is feeding on leaves (in summer), leaves and young stems (in winter) or old stems and new shoots (in spring). It defaecates about 48 times per day, the faeces totalling 20 kg

or more in weight. The nutrient level of bamboo apparently remains relatively constant through the year, but while bamboo is always abundant it is time-consuming to gather. Protein intake levels seem adequate, and the prodigious amounts consumed are probably required to obtain enough digestible carbohydrate, particularly in spring, the lean season for pandas. At this time of the year, the limitation on the animals' intake of food may be their guts' ability to deal with the bulk.

A panda in the Wolong study area spends most of its life taking in food. It forages for 13 hours a day, rests (conserving scarce energy) for 10 hours, and fits everything else (which is not much — drinking, travelling, grooming, defaecating, scent-marking, playing and socializing) into the one remaining hour. It is no wonder therefore that the home ranges and the daily distances travelled are both small, and the animals very largely solitary.

One chapter brings together the information on reproduction, breeding behaviour and communication from captive studies in zoos and from this first major field study. There is probably delayed implantation; this is suggested by the extraordinarily variable gestation period (ranging between 97 and 163 days in fewer than 30 measured pregnancies in captivity), the time lag after copulation before a progesterone rise, and the minute size (90–130 g) of the one or two offspring at birth. At about 0.011 per cent of maternal weight, these are the smallest eutherian mammal babies known.

Anatomical, physiological and behavioural features are used to re-examine the old problem of giant panda phylogeny. The species appears in many independent respects to be quite closely related to the bears, whereas the much smaller red panda seems to be close to the Procyonids (the raccoon and its relatives). But in many other respects giant pandas seem to be merely enlarged red pandas and phylogenetically close to them. There has clearly been a much greater degree of convergence in evolution than is comfortable to taxonomists. The authors' solution to the contradictions is the more usual one of considering red and giant pandas to be the closest relatives, and therefore of necessity distancing both from both bears and raccoons. This is not the conclusion of the most recent molecular studies in which O'Brien *et al.* (*Nature*, in press) have asserted that the giant panda is close to the bears and the red panda close to nothing else.

The data on giant pandas in the wild will be useful in managing the small wild population, estimated at about 1,100, mostly in a few circumscribed reserves. But equally valuable will be the fact that the study has focused international interest on the plight of the giant panda and on the steps which will need to be taken

for the conservation of the species and its habitat.

The long-cycle flowering and subsequent temporary die-off of bamboo, and consequent starvation of pandas, has received a great deal of publicity. The situation is very complex. In "proper" panda habitat, with a variety of bamboo species, each flowering intermittently but asynchronously, the pandas' food supply does not disappear. But human pressure has in particular resulted in the loss of the lower-altitude species of bamboo in many areas, in effect removing the pandas' emergency alternative rations. The animals can and do switch between different bamboo food types, as this study showed; but it also showed that they have very little spare time to spend in searching for and gathering their food. They are near the limits of their existence, for several reasons. The remedies for the situation will form the basis of the research team's next report. We shall await it just as eagerly. □

Matter of a letter

Stillman Drake

The Galileo Affair: A Meeting of Faith and Science. Edited by G. V. Coyne, M. Heller and J. Zyciński. *Specola Vaticana, V-00120 Stato Città Del Vaticano, Vatican City State; 1985. Pp.179. Pbk \$7 (individuals), \$9 (libraries).*

In 1979 the Pope expressed concern that Galileo had suffered at the hands of persons and instrumentalities of the Catholic Church. Citing a passage from Galileo's open letter of 1615 on religion and science, addressed to the Grand Duchess of Tuscany, he implied that Galileo's theological position was sounder than that of his judges at his trial for suspected heresy, in 1633. The Pope proposed a thorough re-examination of the Galileo affair, placing blame wherever it historically belonged.

Several publications at Vatican City have subsequently appeared. Among the first was the complete official text of all documents relating to the affair now extant at Rome. Most recent is this book, the proceedings of a conference held at Cracow in 1984 and attended by historians, philosophers, scientists and theologians. History of the Galileo affair occupies the first section, followed by sections on Galileo and science, and on cultural repercussions of the Galileo affair.

As translator of Galileo's letter of 1615 and of his books, I oppose the claim (p.30) that the former "is filled with assertions that the Earth's motion, both diurnal and annual, can be conclusively proved by

necessary demonstrations based on sense experiences". No such categorical assertion was made. The part of the letter cited says no more than that after decades of unopposed study, Copernican astronomy was being attacked by philosophers just when it was beginning to appear well-founded by manifest experiences (telescopic) and necessary demonstrations (mathematical).

One such set of foundations was the phases of Venus announced at the beginning of 1611. Another was eclipses of Jupiter's satellites, published in 1613 with some predictions by Galileo and his remark that motion of the Earth had to be considered in calculating them. His calculations showed that the Earth was not at, or even near, the centre of Jupiter's orbit. The scholar concerned is also mistaken in assuming that Galileo alluded to his explanation of tides, which involved no measurements, mathematical calculations or predictions subsequently verified observationally.

In 1615 Galileo openly stated his Copernican belief; no action had yet been taken by theologians on the matter. The purpose of his letter was to show that any action would be untimely, not to prove any scientific conclusion. In 1616 an edict regulating Copernican books was issued. Thereafter Galileo discussed the matter only hypothetically, having promised in his letter to abide by Church action if, contrary to his advice, any were taken.

Thorough re-examination of the Galileo affair as proposed by the Pope is

Galileo — from rhetoric to science.

Mary Evans

still far from accomplished. Another scholar at Cracow writes (p.137): "The revolutionary ideas of Galilean astronomy were due to fortunate conjectures and insights which had no critical empirical confirmation before 1838". No scientist altered his astronomy because of Bessel's observations. Moreover Galileo's calculations of satellite eclipses were not fortunate conjectures. Whether philosophers should reject them as critical empirical confirmation of the Earth's place and motions is at least questionable. Philosophy and rhetoric are no longer science, as they were until Galileo separated them from it.

AIDS: the scientific story so far

June Goodfield

A Strange Virus of Unknown Origin. By Jacques Leibowitch. Translated by Richard C. Howard. *Available Press (Ballantine, New York); 1985. Pp.172. Pbk \$4.95 (United States), \$6.50 (Canada).*

ACQUIRED immune deficiency syndrome, AIDS, struck medical consciousness at a time when, as Robert C. Gallo points out in his foreword to this book, prominent scientists were predicting the end of the great human infectious epidemics. Though the disease had certainly already been present in a few special localities, it appeared where it might have been least expected, namely in technologically advanced, relatively healthy societies.

The medical community might have been taken by surprise, but the cause of AIDS was discovered with a speed probably unparalleled in the history of infectious diseases. A new virus, unique to human beings, preferentially attacks the helper T-lymphocytes, the very cells whose activity is crucial in the mounting of an adequate immune response. The immune deficiency thus provoked lays the victim open to a whole variety of invariably fatal opportunistic infections. As they watch the spread of AIDS gather momentum, medical scientists are realizing that, far from being over, a new, dangerous period of infectious epidemics may just be starting.

We are fortunate that a scientist involved in research into this disease from its very beginning has now written this excellent, slim book. Jacques Leibowitch is a clinical immunologist who has been both close to the problem and totally committed to its solution. Here he successfully demystifies AIDS, recognizing, as we all should, that to know your enemy well is the first step towards victory. Taking us on a survey through the history and origins of the epidemic, he presents a comprehensive and authoritative clinical and epidemiological picture that culminates with sections on prevention and the prospects for treatment — not at all bright as of now.

Everyone from professional scientists to the general public will find this book of great value. It is marred, however, by one stylistic fault. Though at the beginning the writing is fluent and witty, the book finishes in a series of choppy, condensed paragraphs covered liberally by sub-headings, so that it takes on the quality of a briefing paper for a select committee. □

June Goodfield is Adjunct Professor at Cornell University Medical College, 1300 York Avenue, New York, New York 10021, USA, and author of Quest for the Killers/From the Face of the Earth (Birkhäuser/André Deutsch, 1985).

Rural poverty breeds fertility

from Alok Vajpayee

The conditions of village life in rural India create the need for large families. Reduced fertility will come only with improvement.

THE Family Planning Programme (now known as the Family Welfare Programme) has been in operation in India since 1953. The main approach is to fix targets for sterilization operations and other methods of contraception for each area and to press the responsible authorities to achieve them.

This approach is unnatural, because most villagers in India need large families. Motivating them to adopt family planning is a difficult task. The more primitive the way of life the larger the family they need. This is a matter of survival, not simply an option as many villagers well realize.

Of course, the villages are changing, but very slowly.

The urbanization of the villages is followed by a change in life style. And when a village becomes a town the residents will need smaller families. The rural population of India resides in some 576,000 villages, 55 per cent of which contain fewer than 500 persons and 23 per cent of which have between 500 and 1,000 persons (these data and others in this article are from *Health Statistics of India — 1984*, published by the Ministry of Health and Family Welfare). The smaller the village, the greater will be the need for a large family.

Rural life is harder than urban life, which is why a rural family needs more working hands. In the villages, a family must itself do almost all the work required for its survival. In other words, a rural family is more self-sufficient than an urban family. Take, for example, water supply and the disposal of domestic liquid and solid wastes. For both tasks, an urban family does not have to exert itself at all. Water is supplied to houses through pipes and, for the disposal of liquid wastes and excreta, there is a public sewer system.

Services

In villages, these tasks demand careful attention. According to official statistics, in 1984 some 83,000 villages were without even a single source of year-round drinking water. People have to go and carry water, sometimes from a source miles away from the home. For defaecation, almost 100 per cent of the rural population goes to the fields, outside the villages. In the absence of a proper drainage system and a piped-water supply, because of the space available in village houses, the financial constraints and the lack of technical expertise in the villages for the con-

struction and maintenance of sanitary latrines, it is better for them to go into the open for defaecation than to construct and maintain a latrine in their houses.

In the cities one can purchase all types of services; there are laundry services for washing clothes, crèches to look after the children . . . and many other types of service. In the villages, by contrast, such services cannot be purchased; instead, those considered essential must be performed by the family itself.

Electricity makes life extremely comfortable and saves much human and animal labour. But by 1983, about 275,000 villages had not been electrified while even in those with electricity, the supply is erratic and is frequently interrupted.

Agriculture is the main occupation of the villagers and needs a great deal of human labour, at least as practised by most Indian farmers. For the purchase of household items, clothes, utensils and so on — the majority of villagers depend on weekly markets which are held in larger villages, or they may go to a nearby city. But there is a great problem of transport. Of the villages of India, 53 per cent were not connected by all-weather roads in 1982.

So therefore, all of the tasks performed by a rural family require a great deal of human labour and time, and only a large family is suitable for such a life style.

In the villages, life and property are much more insecure than in the cities. Robberies, land disputes, murders, thefts and familial rivalries are common, but the nearest police station is usually too far away to be contacted quickly, while the law enforcement agencies are lax. At any one time, most of the police force is engaged on law enforcement in the cities, handling strikes and regulating traffic, for example. Even the mass media have an urban bias. A quarrel or theft in a metropolitan city may hit the headlines of a national daily while a major atrocity on villagers may go unnoticed. Most of the national newspapers and magazines suffer from myopia.

A large family gives a sense of security against such happenings as well as 'insurance' against natural calamities such as floods, fires and the like.

The very old and the very young, the sick and pregnant need special care and attention. A large family can deal with sudden crises such as illness and the normal stresses of birth and old age without

help from outside. A young grandchild may be assigned the duty of watching grandma and helping her, or vice versa.

In the villages, professional expert help cannot be easily obtained. According to an estimate made in 1979–80, only 10–15 per cent of births in India were conducted by trained attendants. Most of the rural population depends on quacks for treatment.

Mortality

Inevitably, the death rate is higher in the villages than the cities. In 1982, the crude death rate for the rural population was 12.9 per 1,000 population, while in the urban areas it was 7.4 per 1,000 population. There is a positive correlation between death rate and birth rate; the higher the mortality, the greater will be the fertility. The collapse or removal of a family member in a small family of four or five, with only a few relatives, will have far more serious consequences than in a large 'unplanned' family.

Mortality in childhood, especially infant mortality and under-five mortality, is very high in the villages. The infant mortality rate in 1980 was 124 per 1,000 live births in the villages and 65 per 1,000 live births in urban areas. The under-five mortality rate in 1980 was 46.1 per 1,000 for rural areas and 22.2 for the urban areas. The smaller the chances of survival of a child, the higher will be fertility. Villagers feel that they should produce too many children if they are to be sure that at least one or two sons will survive to provide care for their parents in old age.

So if the government wishes family planning to be a success rather than a mere slogan, it must provide intensive maternal and child health facilities, giving sufficient health coverage to the mother and her new-born. Child-health is the best motivator of family planning.

As things are, the villagers of India need large families. Overall socio-economic uplift and rural development will bring about a change in life-style that will diminish the need and will ultimately reduce fertility. Rural electrification, better transport facilities for rural areas, the construction of good roads, better medical facilities, the provision of a piped water supply and the like are thus the long-term agents of demographic change. □

Control of eukaryotic messenger RNA synthesis by sequence-specific DNA-binding proteins

William S. Dynan* & Robert Tjian

Department of Biochemistry, University of California, Berkeley, California 94720, USA

The enzymatic machinery that carries out RNA synthesis provides the cell with the means to adjust the patterns of transcription in response to environmental and developmental signals. In eukaryotes, this regulation is mediated in part by promoter-specific transcription factors, which are DNA-binding proteins with the ability to discriminate between distinctive DNA sequence elements found in the promoter regions of different genes. The presence of these factors bound to DNA enables other components of the transcriptional machinery, including the RNA polymerase, to initiate transcription with selectivity and accuracy.

THE principal method of identifying the DNA sequence elements that control transcription in eukaryotes has been to mutagenize DNA sequences near the start of transcription, then to test the altered templates either by reintroduction into the cell or by introduction into some experimental substitute, such as an *in vitro* transcription system. Accumulation of new RNA or protein is measured after a period of time, and from this an inference is made about the effect of sequence changes on promoter strength. These studies have shown that, although promoters for protein-coding genes vary in sequence, they are organized according to a common plan (Fig. 1).

Many promoters have an element called a TATA box, with a consensus sequence 'TATAAA', located 25–30 base pairs (bp) upstream from the beginning of the transcribed sequence (for review, see ref. 1). Mutation in this region generates 5' (upstream) heterogeneity in the transcripts^{2–4}, although the overall level of RNA synthesis may not be significantly reduced. Further upstream from the start site of transcription is a region containing one or more additional promoter elements. Some upstream elements, such as the 'CCAAT' or 'GGGCGG' homologies, have now been found in many different promoters, whereas others, such as the metallothionein metal regulatory element^{5–7}, or the heat-shock regulatory element⁸, have a more specialized role. As we shall establish, upstream promoter elements are a principal target for the action of promoter-specific transcription factors.

The activity of many promoters is modulated by an enhancer, which is a separate regulatory element. The enhancer must be on the same molecule of DNA, but can be 1,000 bp or more from the promoter, and may be located either upstream or downstream from the transcription start site (Fig. 1)^{9–12}. The prototype enhancer is found in simian virus 40 (SV40), a DNA tumour virus^{9,10,12–14}, but control elements with similar properties have since been found in other viruses and in the cellular genome (for example, refs 11, 15–17). Some enhancers are tissue-specific^{18–26}, whereas others mediate transcriptional responses of certain genes to steroid hormones²⁷.

Protein factors in transcription

The understanding of promoter function gained by analysis of DNA sequences has certain limitations, which can be overcome only through identification, purification and characterization of the proteins required for transcription. One would like to know how the proteins that bind to promoter and enhancer elements bring about transcriptional regulation and, in particular, to understand how the abundance and activity of transcription factors change through cell growth and development.

The enzyme responsible for mRNA synthesis, RNA polymerase II, differs from prokaryotic RNA polymerase holoenzyme in that it seems to lack any inherent ability to recognize promoters in an *in vitro* reaction. It has recently become clear that crude extracts from eukaryotic cells contain factors that impart promoter specificity to the purified RNA polymerase II and allow *in vitro* initiation of transcription at the same start sites as are used *in vivo*^{28–33}. Some of these factors seem to be required for initiation at all promoters^{34–40}, whereas others are required for initiation at certain promoters but not others. Many of these latter, promoter-specific, factors bind DNA sequences in their respective target promoters. DNase footprinting⁴¹ has been used to measure this site-specific binding in several instances^{39,40,42}. In the ideal case, the binding and transcriptional properties of a factor can be related experimentally, with stimulation of transcription requiring sequences within the binding site, and moreover, with binding and transcription stimulatory activities co-purifying during fractionation of the extract.

The promoter-specific factor Sp1

Sp1, a protein possessing many of the characteristics described above, is a factor obtained from cultured human cells and required for transcription of SV40 (ref. 37). Activation of transcription by Sp1 requires a well-defined upstream element, which in SV40 occupies a region 50–100 bp upstream from the start site for early viral RNA transcription^{14,43–45}. When this sequence is deleted, the early promoter is no longer able to respond to Sp1 (ref. 42) and, inversely, when the sequence is fused to a heterologous TATA box element, the hybrid promoter becomes Sp1-responsive (D. Gidoni and R.T., unpublished). The Sp1 target element seems to function bidirectionally⁴⁶, and plays a role in directing late viral transcription from the opposite strand of the DNA^{14,42,45,47–51}.

Binding experiments show that purified Sp1 interacts directly with the sequences required for the transcriptional response⁴². The sequence asymmetry of the Sp1-binding site is a distinctive feature; unlike the binding sites for prokaryotic transcription

Fig. 1 Arrangement of DNA sequence elements controlling transcription of a typical eukaryotic protein-coding gene. The enhancer may be located upstream or downstream of the site of transcriptional initiation.

* Present address: Department of Chemistry and Biochemistry, University of Colorado, Boulder, Colorado 80309, USA.

factors, such as the lactose operon repressor, the phage λ repressor, or cyclic AMP receptor protein (for review, see ref. 52), there is no suggestion of dyad symmetry in the region. Sp1-DNA contacts detected by dimethylsulphate protection fall within a sixfold repeated sequence moiety ('GGGCGG'; ref. 53). Sp1 forms strong contacts with three of these GC boxes and weakly contacts two others (Fig. 2). Contacts have so far been detected only in the major groove of the DNA and on one strand. Alteration of individual GC boxes by oligonucleotide-directed mutagenesis suggests the presence of five independently bound protomers within the overall region, with each Sp1 protomer contacting one GC box and protecting ~20 bp from DNase (D. Gidoni, J. Kadonaga, H. Barrera-Saldaña, K. Takahashi, P. Chambon and R.T., unpublished).

Other Sp1 binding sites

When Sp1 was first isolated, its interaction with SV40 was thought to be unique. Recently, however, Sp1 has been shown to be required for *in vitro* transcription of several genes of herpes simplex I virus, including immediate early gene 3 (ref. 95) and a delayed early gene, thymidine kinase⁹⁶. The pattern of Sp1 binding differs from that in SV40, with each control region in the herpes virus containing multiple separate 'unit sites' for Sp1 binding (Fig. 3). Each unit site covers ~20 bp and presumably accommodates a single Sp1 protomer. Binding at the thymidine kinase promoter is particularly interesting because Sp1 seems to interact with the 'distal elements' previously defined by mutational analysis^{54,96}. Activation seems to require both Sp1 and a second, as yet unidentified, factor that binds in the region between two Sp1-binding sites.

In addition to these viral genes, several cellular sequences also interact with Sp1. A DNA segment from the monkey genome, which functions *in vivo* as a bidirectional promoter element⁵⁵, contains two Sp1-binding regions, one of which, the β -site, is shown in Fig. 3⁵⁶. Multiple Sp1-binding sites are also found in 5' flanking sequences of the mouse dihydrofolate reductase (*dhfr*) gene (W.S.D., S. Sazer, R.T. and R. Schimke, unpublished; for sequence, see ref. 57). The monkey β -binding region is relatively large and may be a complex binding site, like that of SV40. The mouse *dhfr* promoter, by contrast, shows unit binding sites reminiscent of those found in the herpesvirus promoters. All the Sp1-binding regions contain one or more perfect copies of the GC box hexanucleotide GGGCGG, which may be present in either orientation with respect to transcription. Not all GC boxes bind Sp1 equally well, and sequences outside the core hexanucleotide seem to modulate the efficiency of binding. A consensus sequence, compiled from 19 individual strong binding sites, is shown in Fig. 3⁹⁷.

Recently a number of additional GC box-containing promoters have been described. These include promoters for cellular genes, such as human metallothionein-1A (ref. 58), hamster hydroxymethyl-glutaryl coenzyme A reductase⁵⁹, mouse hypoxanthine phosphoribosyl transferase⁶⁰, mouse adenine phosphoribosyl transferase⁶¹, human adenosine deaminase⁶², and rat type II procollagen⁶³, as well as promoters for other viral genes, including herpes simplex I immediate early genes 4 and 5 (ref. 95) and AIDS retrovirus (refs 64-66; K. Jones, J. Kadonaga, P. Luciw and R.T., unpublished). Some of these putative binding sites have been tested in our laboratory for their ability to bind Sp1, but in most cases binding is merely predicted from the DNA sequence.

No shared regulatory feature is evident among the diverse promoters in which actual or potential Sp1-binding sites have been found, and thus we cannot at present explain why some promoters have Sp1-binding sites and others do not. It is possible that Sp1 provides a framework to which other regulatory proteins may bind; it is also possible that Sp1 provides a basal, constitutive level of transcription that is then modulated by other positive or negative regulatory factors. The occurrence of binding sites in the transcription control regions of unrelated viruses suggests that Sp1 is not only widespread among different cells but also

Fig. 2 The Sp1-binding region of SV40. Ellipses represent Sp1 molecules; darker shading indicates higher-affinity binding. Filled GC box moieties are fully protected from dimethylsulphate modification, the hatched GC boxes are partially protected and open GC boxes are unprotected. The initiation sites for late RNA are heterogeneous; only the most Sp1-proximal is drawn.

readily available within the cell to facilitate rapid viral gene expression on infection.

Heat-shock transcription factor

A factor that is similar enzymatically to Sp1 is involved in directing the heat-shock transcriptional response. When cells of any organism are exposed to abnormally high temperature, several heat-shock mRNAs are induced. In *Drosophila*, and apparently in mammalian cells as well, the induction of transcription is mediated by a conserved heat-shock regulatory sequence found in the upstream region of the promoters for heat-shock RNAs (ref. 8; for review, see ref. 67). A heat-shock transcription factor (HSTF) has been isolated from *Drosophila* that seems to interact with this element in a manner analogous to the interaction between Sp1 and its recognition sequence⁴⁰. In the promoter for the relative molecular mass (M_r) 70,000 heat-shock protein, HSTF binds 40-95 bp upstream from the TATA box (Fig. 4). Like Sp1, the HSTF binds to its target sequence in the absence of RNA polymerase II and is promoter-specific, stimulating transcription of the heat-shock gene but not, for example, the actin 5C gene⁴⁰.

One of the attractive features of the heat-shock system is that the *in vivo* role of the factor-sequence interaction has also been analysed. Digestion of chromatin with exonuclease indicates that sequences in the HSTF binding site are accessible in normal cells, but protected, presumably by HSTF, in heat-shocked material^{68,69}. HSTF can be isolated in more-or-less equivalent amounts from normal and heat-shocked cells; therefore, its appearance at the promoter during the heat-shock response probably reflects a change in localization or properties rather than *de novo* synthesis. The nature and mechanism of this change remains to be elucidated.

Other DNA binding factors

The degree to which the effects of upstream elements are reproduced *in vitro* varies depending on the promoter and the way in which the extract is made⁷⁰. With some promoters, such as rabbit β -globin, upstream sequences required for *in vivo* expression have had no effect *in vitro*⁷¹. In other instances, upstream sequences have had a substantial effect on *in vitro* transcription. In addition to the promoters mentioned specifically above, upstream sequences have been shown to be required for maximal *in vitro* transcription of the adenovirus-2 major late promoter^{70,72}, the silkworm fibroin promoter⁷³, one of the sea urchin histone promoters⁷⁴ and the *Drosophila* alcohol dehydrogenase promoter⁷⁵. The dependence on upstream sequences implies the presence of corresponding factors in cell extracts, and at least in the case of the alcohol dehydrogenase and adenovirus promoters, it has been possible to detect the binding of these factors directly, by DNase footprinting (ref. 75, W. Morgan and R.T., unpublished; R. Roeder, personal communication). Although not yet correlated with an upstream element, the elevated histone promoter transcription seen with extracts from S-phase cells may reflect the functioning of yet another promoter-specific factor⁷⁶.

In addition to proteins that bind upstream sequences, a factor that binds the region containing the TATA element has been

Fig. 3 Different arrangements of Sp1-binding sites. Ellipses represent Sp1 molecules, with darker shading indicating higher affinity binding. Arrows within Sp1 symbols represent GC boxes, with the arrow pointing in the 5' → 3' direction on the G-rich strand of DNA. For clarity, only those GC boxes that actually bind Sp1 are drawn. Some promoter regions have additional GC boxes that do not bind Sp1, possibly because of steric hindrance from Sp1 at adjacent sites. The GC box consensus sequence was obtained by comparison of 19 strong binding sites⁹⁷. Dotted rectangle in herpes thymidine kinase gene represents an additional factor binding between Sp1 molecules.

identified both in *Drosophila*³⁹ and in mammalian cell extracts (ref. 77; W. Morgan and R.T., unpublished; M. Sawodogo and R. Roeder, personal communication). The *Drosophila* factor interacts with several *Drosophila* promoters, including those of the actin, histone H3 and histone H4 genes³⁹. Binding (as assayed by DNase footprinting) occurs in the absence of upstream factors, with the protected region extending from about -40 to +25.

Initiation of transcription

In addition to the site-specific DNA-binding proteins described here the actual initiation of transcription requires RNA polymerase II and at least three other enzymatic factors (refs 34–39; D. Reinberg and R. Roeder, personal communication). Under appropriate conditions, these proteins form a complex at the promoter before initiation of transcription.

Various kinetic and order-of-addition experiments have been of some help in elucidating the steps involved in complex assembly. Davison and coworkers⁷⁷ showed by an indirect depletion assay in a mammalian system that DNA fragments containing a functional TATA box homology could sequester an essential transcription factor from the reaction. Fire and coworkers⁷⁸ carried this approach further and developed a model for ordered assembly of a complex at the adenovirus major late promoter. Their results suggest that factors present in two fractions bind first, in an indistinguishable order, followed by association of RNA polymerase II and, in a final rapid step, factors present in a third fraction. In the absence of nucleoside triphosphates, no initiation occurs and the complexes are stable for at least an hour. Although it is important to interpret these experiments cautiously, because separation and purification of the components might cause events to happen differently *in vitro* than in the cell, this sort of experiment seems to be the best available tool for elucidating the roles of the multiple factors that participate in the initiation reaction.

A marked inhibition of RNA polymerase II activity is seen when β - γ -imido ATP (AMP-PNP) is substituted for ATP in the promoter-directed *in vitro* transcription reaction⁷⁹. The ATP analogue, which cannot be hydrolysed at the β - γ position, apparently fails to satisfy a requirement for hydrolysable adenosine nucleotide during the initiation reaction. AMP-PNP can be hydrolysed normally at the α - β position, and in the post-initiation elongation phase of the reaction can be incorporated normally into RNA. Addition of deoxy ATP to a reaction containing AMP-PNP restores the ability to initiate even though

the deoxy compound cannot be incorporated into the nascent RNA chain^{37,80}, clearly demonstrating that the requirement for β - γ hydrolysis is separate from elongation. The requirement for a hydrolysable adenosine compound is independent of which base is present at the 5' terminal position in the RNA, and has been seen only with RNA polymerase II and not with the other eukaryotic RNA polymerases. As yet, it is not known whether hydrolysis is carried out by the polymerase itself, or by one of the additional factors involved in initiation.

How factors influence transcription

The role of upstream factors should be viewed in the context of their interaction with other components of the transcriptional machinery. In the simplest case, an upstream factor might bind next to the transcriptional initiation site, thus inducing a conformational change in either the DNA or in other proteins that make up the initiation complex (Fig. 5a). An example of a promoter that may be activated by this mechanism is that for the *Drosophila* *M*, 70,000 heat-shock protein, where the most proximal heat-shock recognition sequence is only 15 bp from the TATA box. In other heat-shock promoters, however, as well as many of the Sp1 responsive promoters (refs 67, 81; see also Fig. 3) the upstream factor binding site may be situated farther from the initiation site, making direct protein-protein contact less likely as a mechanism for transcriptional activation. Moreover, many promoters have multiple binding sites for upstream factors, with the most distal sites clearly out of range for direct contact with proteins bound at the initiation site.

There are several possible models that could explain the apparent ability of upstream factors to act at a distance. After initial binding to the recognition site, a factor might shift positions to make productive contact with other proteins at nearby sites (see Fig. 5b). A necessary consequence of this model is that an input of energy would probably be required to allow the factor to dissociate from its high-affinity binding site and move along the helix. An alternative model is that the upstream factor might remain in place but induce a conformational change in the DNA helix, such as an unwinding; in this case, the arrow in Fig. 5b can be taken to represent the propagation of the conformational strain through the DNA. A different possibility is drawn in Fig. 5c, where a second factor binds alongside the first to create a continuous scaffold of protein. This interstitial binding may occur in herpes thymidine kinase, where a second factor has recently been found to bind between the two Sp1 sites (see Fig. 3). Another model supposes that factors bound at multiple upstream sites allow DNA to condense into a compact nucleoprotein structure (Fig. 5d). There is as yet no direct evidence for such a structure, although similar models have been proposed to explain the role of multiple binding sites involved in site-specific recombination and DNA replication in bacteria⁸² and for enhancer activation of promoters in eukaryotes⁸³.

Some upstream elements function bidirectionally. This might be expected with the heat-shock element, where the consensus recognition sequence has a dyad symmetry. Similarly, in herpes thymidine kinase, two Sp1 binding sites are present in opposite orientations, making it easy to explain the activity of the upstream elements when their overall orientation is inverted⁸⁴. The properties of the SV40/Sp1-binding region are more difficult

Fig. 4 Arrangement of HSTF binding sites in the promoter for the *Drosophila* *M*, 70,000 heat-shock protein. Stippled ellipses cover region where binding has been reported; open ellipses indicate regions of potential HSTF binding further upstream from the initiation site.

Fig. 5 Models for the action of promoter-specific factors. *a*, Transcription factors (stippled) bound to upstream elements, in direct contact with other proteins (shaded) bound at the initiation site; *b*–*d*, action at a distance. *b*, Upstream factor shifts position to contact proteins at initiation site, or alternatively, alters conformation of DNA, with effect felt at initiation site. *c*, Additional proteins bind interstices to create a continuous scaffold of protein in the promoter region. *d*, Transcription factors condense into a compact nucleoprotein structure, with looping-out of intervening DNA.

to explain, however, because despite its marked sequence asymmetry, the region is clearly involved in the genesis of transcripts from both viral strands^{14,43–45,47–51} and retains its ability to direct early RNA synthesis when inverted⁴⁶. This apparent paradox has not been resolved, although a simple possibility that cannot yet be excluded is that activation of transcription in opposite directions occurs by different and independent mechanisms.

Activation of transcription by enhancers

One persistent question in the field is whether enhancers are fundamentally different from upstream promoter elements of the sort that interact with Sp1 or HSTF. Clearly, as more experiments have been done, many upstream promoter elements have been found to have characteristics once thought to be distinctive properties of enhancers, such as bidirectionality and a degree of flexibility in spacing^{42,46,81,84}. So far, however, only enhancers have shown an ability to influence transcription over distances of a kilobase or more, and to work upstream or downstream of the promoter.

It seems probable that enhancers, like promoters, will turn out to be regions of interaction for site-specific DNA binding proteins. This has been shown directly for the enhancer-like glucocorticoid response elements of murine mammary tumour virus and the human metallothionein II_A gene, both of which bind glucocorticoid receptor^{5,85–87}. It is uncertain whether enhancers are sites for binding of a single protein or, like promoters themselves, are sites for assembly of a multiprotein complex, with some proteins binding directly to the DNA and others involved in other aspects of the reaction. There is evidence that different enhancers compete with each other for limiting components in the cell^{87,88}, which is consistent with the idea that various cellular and viral enhancers interact with at least some common factors.

Several groups have been successful in showing an effect of the SV40 enhancer in an *in vitro* system where transcription is activated 10-fold or more under optimal conditions^{89–92}. It is not yet certain, however, that the activation is caused by the enhancer *per se*, and not to other sequences, such as elements of the late promoter, that are present in the same region of SV40. In addition, the unique and distinguishing feature of enhancer activity, the stimulation of promoters over distances of ≥ 1 kilobase (kb), and from downstream of the gene, has not yet been demonstrated with an *in vitro* system.

Little more is known now about how enhancers transmit their effects over distances than when these elements were first discovered. Assuming that enhancers act at the level of initiation of transcription^{93,94}, it seems evident that they must facilitate some rate-limiting step; moreover, if they are binding sites for proteins they should follow the ordinary rules governing pro-

tein-DNA interactions. The models discussed previously for upstream promoter elements are therefore likely to be applicable to enhancers as well. A looping out of intervening DNA, in particular, could explain several features of enhancer-promoter interactions⁸³, and would allow a DNA-binding protein to exert its effect over any distance.

Conclusions

In this review we have chosen to focus on experiments involving biochemical fractionation and analysis of proteins from cell extracts. To keep this review brief, we have largely omitted discussion of several valuable alternative approaches. These include the use of enzymatic and chemical probes for analysis of chromatin structure in promoter and enhancer regions, as well as attempts to obtain mutants in the genes encoding trans-acting factors. Similarly, we have not discussed trans-acting factors such as the adenovirus E1A protein, which seem to modulate transcription by a mechanism other than sequence-specific DNA binding.

Although many details remain to be established, recent work clearly indicates the existence of promoter-specific transcription factors that recognize distinctive sequence elements found 40–100 bp upstream from the initiation site in eukaryotic protein-coding genes. Several such factors have been isolated and each factor recognizes a different sequence element. Binding activates transcription and allows the transcription machinery to discriminate between different promoters in an *in vitro* reaction. Within a promoter there are often multiple binding sites for the same or different factors, and the distance to the start site of transcription can vary significantly, suggesting that a mechanism exists for transmitting the activating signal through at least short stretches of intervening DNA. In addition to the sequence-specific DNA binding proteins, several other factors required for transcriptional initiation have been partially characterized, and these proteins, together with RNA polymerase, assemble via an ordered pathway into a functional preinitiation complex.

We thank many friends and colleagues for their ideas and comments on the manuscript. This work was supported in part by the National Cancer Institute.

Residence time of thorium, uranium and lead in the mantle with implications for mantle convection

S. J. G. Galer & R. K. O'Nions

Department of Earth Sciences, University of Cambridge, Downing Street, Cambridge CB2 3EQ, UK

The residence times of thorium, uranium and lead in the upper mantle are estimated at ≤ 600 Myr, and should be similar for related elements that are strongly concentrated in the continental lithosphere. Their upper mantle abundances are close to steady state and are mostly supported by entrainment of material from a lower mantle layer with long-term convective isolation. These lithophile trace elements and rare gases, such as ^3He , are effective chemical probes of the deeper mantle.

ONE of the main aims of geochemistry is to quantify the mass transfer processes that have occurred between different portions of the Earth, such as those responsible for the generation of the continental crust and atmosphere. The development of the continents, for example, has resulted in a marked transfer of the principal heat-producing elements (K, U and Th) and related large-ionic-radius trace elements from the mantle to the crust. A limit on the proportion of mantle involved in forming the continents has been imposed from the mass balance of those parent and daughter atoms involving the radiogenic isotopes of Nd, Sr, Hf and Pb (refs 1-4). These geochemical considerations together with those of the primordial and radiogenic components of the rare gases⁵ have been central to arguments as to whether convection extends throughout the whole mantle or is separated into two layers. In the latter case of layered convection, attention has been drawn to the requirement for transport of at least heat and He across the separating boundary layer⁶.

The depleted character of the upper mantle is evident in both the elemental and isotope compositions of mid-ocean ridge basalts (MORB). In particular, trace elements that strongly partition into silicate melts (bulk solid/liquid distribution coefficient $D_1 \ll 1.00$), such as Cs, Rb, K, Th, U and light rare earths, are estimated to be present at $\leq 20\%$ of their initial

abundances¹⁻⁴. This depleted character is evident not only in Recent MORB and Phanerozoic ophiolites but also in some Archean komatiites and basalts^{7,8}, indicating that part of the mantle has been depleted for $\sim 3,000$ Myr. Because elements with the lowest D_1 values are extracted more efficiently than those with larger D_1 during melting, it can be anticipated that some relationship exists between transport, distribution coefficient (D_1), residence time (t_r) and degree of mantle depletion.

In this article, we suggest that limits can be placed on the residence times of Pb, Th and U in the mantle, and that the upper mantle has close to steady-state concentrations for these elements. The results have important implications for the origin of chemical and isotope heterogeneity in the mantle, the degree of boundary-layer interaction in a convectively-stratified mantle, and the early differentiation of the terrestrial planets.

Residence times

Th and U are highly incompatible elements that are strongly depleted in the Earth's upper mantle. The Th/U ratio or κ value ($^{232}\text{Th}/^{238}\text{U}$ ratio) of the bulk Earth has been estimated at ~ 3.85 from the Pb isotope compositions of conformable lead ore deposits^{9,10}, in good agreement with the value of 3.9 ± 0.1

n = number of samples. $\bar{\kappa}_{\text{Pb}} = \{^{208}\text{Pb}^*/^{206}\text{Pb}^*\}(e^{\lambda^{238}\text{T}} - 1)/(e^{\lambda^{232}\text{T}} - 1)$ where T is the age of the Earth (4,550 Myr), λ_i the decay constant of parent isotope i , and $^{208}\text{Pb}^*/^{206}\text{Pb}^*$ is corrected for primordial Pb (ref. 16). $\kappa_{\text{Th}} = (\lambda_{238}/\lambda_{232})(^{232}\text{Th}/^{230}\text{Th})$ where $(^{232}\text{Th}/^{230}\text{Th})$ is an activity ratio.

deduced from igneous rocks of various ages^{11,12}. The latter value of 3.9 is adopted here for the bulk Earth Th/U ratio, but a precise value is not critical to the central argument.

The present-day Th/U ratio of the upper mantle may be estimated from Th and U abundances or from $(^{232}\text{Th}/^{230}\text{Th})$ activity ratios of MORB, derived by melting the mantle beneath spreading ridge axes. Measured $(^{232}\text{Th}/^{230}\text{Th})$ activity ratios from the East Pacific Rise and other MORB (Table 1) correspond to $\text{Th}/\text{U} \approx 2.5$ in their mantle sources, however; the observation that $1 < (^{230}\text{Th}/^{238}\text{U}) < 1.3$ for most MORB also suggest that Th enters the melt phase preferentially over U and that $D_{\text{Th}} < D_{\text{U}}$ (refs 13, 14). This is consistent with Th/U concentration ratios reported by Jochum *et al.*¹⁵ which range from Th/U = 1.5 to 3.1 as the Th content increases, and should, therefore, be an upper limit on the Th/U ratios of their sources. When taken together, this implies that $\text{Th}/\text{U} \leq 2.5$ in the upper mantle sampled at spreading ridges, or around half of any estimate for the bulk Earth.

An additional estimate of Th/U, albeit a time-integrated average over Earth history, can be calculated from the Pb isotope compositions of oceanic basalts; values of $\bar{\kappa}_{\text{Pb}}$ are derived from the radiogenic additions to ^{208}Pb and ^{206}Pb from their respective parent isotopes ^{232}Th and ^{238}U making allowance for primordial Pb (ref. 16) (Table 1). Most MORB show a restricted range from 3.65 to 3.89, with an average value of ~ 3.75 (Table 1); ocean-island basalts exhibit a larger range ($3.7 < \bar{\kappa}_{\text{Pb}} < 4.2$). Thus, the Th/U ratio that the Pb in oceanic basalts has 'seen' over its history ($\bar{\kappa}_{\text{Pb}}$) is higher than the deduced $\text{Th}/\text{U} < 2.5$ of the upper mantle, but close to the bulk Earth value of ~ 3.9 .

At first sight, these relationships^{11,17,18} appear paradoxical because the low Th/U ratio of MORB, symptomatic of depletion, is expected to be a long-standing feature of the upper mantle. In Fig. 1, the response of the $\bar{\kappa}_{\text{Pb}}$ parameter (and $^{208}\text{Pb}^*/^{206}\text{Pb}^*$) to recent U-Th-Pb fractionations is examined in a simple two-stage model reducing the Th/U ratio from 3.9 to 2.5 at various times in the past. For a range of possible μ values ($^{238}\text{U}/^{204}\text{Pb}$), the Pb now sampled by MORB could not have been in an environment with $\text{Th}/\text{U} = 2.5$ for more than 600 ± 200 Myr.

The simplest explanation for this observation is that the residence time ($\bar{t}_{\text{Pb}}$) of Pb in the upper mantle is short (~ 600 Myr), and, therefore, 'buffered' by the introduction of Pb into this portion of the mantle from another reservoir possessing an approximately bulk Earth $\text{Th}/\text{U} = 3.9$. Such an effect is easier

to sustain if the concentration of Pb in the upper mantle is very low compared with the introduced material. The steady-state residence time ($\bar{t}_i$) for an element (i) is given by $\bar{t}_i = [c_i/c_0]/\dot{m}_i$, where c_i is the steady-state concentration in, and c_0 that of, material added to the reservoir at a mass flux of $\dot{m}_i$ relative to the total mass of the reservoir, so that $\bar{t}_{\text{Th}}/\bar{t}_{\text{U}} = [c_{\text{Th}}/c_0]_{\text{Th}}/[c_{\text{U}}/c_0]_{\text{U}}$. For a steady-state Th/U ratio ($[c_{\text{Th}}]_{\text{Th}}/[c_{\text{U}}]_{\text{U}}$) of 2.5 and a bulk Earth value of 3.9 for the input ratio ($[c_0]_{\text{Th}}/[c_0]_{\text{U}}$), $\bar{t}_{\text{Th}}/\bar{t}_{\text{U}} = 0.64$. Similarly, if it is assumed, for example, that the $^{238}\text{U}/^{204}\text{Pb}$ ratio of the steady-state upper mantle (μ_1) is 6.0, that of the input material (μ_0) is 8.0 and fixing $\bar{t}_{\text{Pb}} = 600$ Myr, then it follows that $\bar{t}_{\text{U}} = 450$ and $\bar{t}_{\text{Th}} = 290$ Myr. The Pb isotope compositions and Th/U ratios can be readily understood in terms of short residence times for these three elements in the upper mantle, but with $\bar{t}_{\text{Th}} < \bar{t}_{\text{U}} < \bar{t}_{\text{Pb}}$ in the same order as their respective D_i .

Fig. 1 Evolution of radiogenic $^{208}\text{Pb}^*$ and $^{206}\text{Pb}^*$ with time in a system with $\text{Th}/\text{U} = 2.5$ assuming a starting time-integrated Th/U ($\bar{\kappa}_{\text{Pb}}$) of 3.9. Lines are constructed for $^{238}\text{U}/^{204}\text{Pb}$ (μ) values ranging from 4 to 16. Comparison with the observed range of $\bar{\kappa}_{\text{Pb}}$ values (and $^{208}\text{Pb}^*/^{206}\text{Pb}^*$) of mid-ocean ridge basalts (MORB) indicates that they have spent 600 ± 200 Myr in a low Th/U environment. $\bar{\kappa}_{\text{Pb}}$ is defined in Table 1.

Fig. 2 The relationship between the steady-state bulk entrainment flux into the upper mantle and the degree of Pb depletion. ϕ_m is the integrated bulk flux over 4,550 Myr assuming a constant bulk flux m_1 , and are both expressed as a fraction of the upper mantle mass. c_1 is the steady-state upper mantle concentration and c_0 that of the entrained material, so that $[c_1/c_0]_{Pb}$ is the Pb depletion factor for the upper mantle. Some restriction on R_{Pb} and hence m_1 and ϕ_m arise from the Pb content of MORB. A value of $X_{Pb} = 1$ corresponds to the R_{Pb} ratio inferred to provide 400 p.p.b. Pb in MORB, assuming that major and trace elements are contributed to MORB from equal mantle source volumes and taking $[c_0]_{Pb}$ as that in the bulk silicate Earth⁵⁸. It is possible that Pb is contributed from a volume X_{Pb} times larger than that giving rise to the major elements in the oceanic crust. Acceptable solutions are likely to be restricted to $1 < X_{Pb} < 3$, corresponding to $0.25 < \phi_m < 0.5$.

Buffering and entrainment

The short residence time implied for Pb necessitates the Pb in the mantle region now sampled in MORB to have been introduced relatively recently from some other reservoir and therefore have a similar Pb isotope signature. Candidates for this external reservoir must be some portion of the continental lithosphere or a lower-mantle region which becomes entrained at its boundary with the convecting upper mantle. The first possibility is the upper continental crust, which is a substantial reservoir for Pb and either directly¹⁹, or as a component of pelagic sediment, might be injected into the mantle. Crustal Pb has a higher $^{207}\text{Pb}/^{204}\text{Pb}$ ratio than MORB that has been used to identify subducted sedimentary contributions to island-arc volcanic suites²⁰. As this elevated $^{207}\text{Pb}/^{204}\text{Pb}$ ratio is predominantly the result of ancient U/Pb fractionation recorded by the decay of now largely extinct ^{235}U , this difference indicates that the bulk of MORB Pb does not come from this source. Moreover, this situation is likely to have pertained throughout the time required to generate such a $^{207}\text{Pb}/^{204}\text{Pb}$ shift ($>10^9$ yr). An upper crustal source, and thus suggestions of substantial recycling of crustal Pb (and presumably other highly incompatible elements) back into the mantle^{21,22} are largely eliminated, although early recycling cannot be excluded. Furthermore, the subduction zone environment apparently efficiently filters continental-derived Pb, and probably also other constituents.

The second reservoir that might feasibly buffer upper mantle Pb is the mantle part of the continental lithosphere²³. This possibility may be best considered with respect to the magnitude of the bulk flux into the upper mantle that is required when integrated over a substantial portion of Earth history; a quantity that is minimized if the concentration of Pb in the upper mantle is very small compared with that in the bulk material added to the reservoir. This 'trade-off' is investigated in Fig. 2, where the concentration ratio R_i is the steady-state concentration of Pb in the upper mantle expressed as a remaining fraction of the input concentration $[c_1/c_0]_{Pb}$ for $t_{Pb} = 600$ Myr, and the total integrated bulk flux (over 4,550 Myr) into the reservoir (ϕ_m) is relative to the mass of the upper mantle.

Some limit on the Pb concentration in the upper mantle may be fixed from a consideration of that in MORB. Assuming that MORB represent a 10–20% partial melt followed by ~40% fractional crystallization, then for an average erupted value of

Fig. 3 A simple box model involving limited bulk entrainment at the interface between an upper and lower mantle region which are otherwise convectively isolated. It is assumed that the mass of the upper mantle box has remained constant over Earth's history, although models involving an increase in this mass and no return flux to the lower mantle box are equally viable. The concentrations of Th, U and Pb in the upper mantle box are assumed to be at steady state and supported by entrainment from the lower, minimally depleted box. The complex fractionation and removal of these elements into the continental lithosphere plus atmosphere is simply described by the single-stage extraction of partial melt as indicated. The differential partitioning of elements into the melt at this point results in variable residence times of elements in the upper mantle box and the steady-state element ratios (such as Th/U) to be different from the ratios in the material entrained at the lower boundary. However, at steady state the element ratios in input and output are equal.

400 parts per 10^9 Pb (refs 17, 24, 25), the source would contain around 20–30 parts per 10^9 . This value may be reduced by a factor X_{Pb} if the oceanic crust samples Pb from a volume that is X_{Pb} larger than from which it extracts major elements^{26,27}. This limit can now be compared with an estimate of the Pb available in the mantle part of the continental lithosphere which probably constitutes $\leq 10\%$ of the upper mantle. Comparatively Pb-rich ultramafic xenoliths from this region contain ~100 parts per 10^9 Pb (ref. 28), only a factor of 10 higher than this upper mantle value (that is, $[c_0/c_1]_{Pb} = 10$). These considerations, therefore, lead to the conclusion that the lithosphere mantle must exchange completely with the convecting upper mantle every few hundred million years to buffer upper mantle Pb, and would have a comparable age. This is, however, inconsistent with the longevity ($>10^9$ yr) of the lithosphere mantle outside the main convective flow documented by the isotope systematics of xenoliths²⁸ and silicate inclusions in diamonds²⁹. Although this does not preclude the possibility that either the mantle or crustal portions of the continental lithosphere make a contribution, they seem not to be the predominant source.

The only viable source remaining for the bulk of this Pb seems to be the lower mantle, which could buffer upper-mantle Pb for the whole of Earth's history without invoking a Pb content exceeding the bulk Earth value (Fig. 2) by virtue of its large mass. If normal ridges strip a much larger volume of mantle of incompatible elements than is indicated by the volume of oceanic crust alone^{26,27} then the estimated concentration of Pb in the upper mantle would be lowered proportionally, and similarly the flux across the boundary required to sustain this Pb. For instance, if this additional volume amounted to between 1 and 3 times that required to support the major elements in the oceanic crust ($1 < X_{Pb} < 3$), it would follow from Fig. 2 that the upper mantle would have been exchanged between a quarter and half by mass over geological time with the lower reservoir. This value is more than a factor of 10 greater than proposed by Olson³⁰ for the exchange across this boundary from scaled convection experiments.

Steady-state upper mantle

The concept of a steady-state upper mantle requires that the input and output fluxes are balanced. This has been used previously⁶ for ^3He , on the assumption that the flux into the oceans from ridges will balance an entrainment flux into the upper mantle from below. The suggested behaviour of Pb implies that, in addition to the rare gases, other highly incompatible elements in the upper mantle may also have reached steady-state con-

Fig. 4 Comparison of bulk distribution coefficient (D_i) and residence time ($\bar{t}_i$) in the upper mantle portion of the model depicted in Fig. 3. The ratio of steady state to input concentration (R_i) is related to the residence time by $\bar{t}_i = R_i/\dot{m}_1$ (see text). Curves are shown for various melt fractions (F , %) corresponding to the output material, but fixing $\dot{m}_1 = 0.0002 \text{ Myr}^{-1}$, $D_{pb} = 0.007$ and $\bar{t}_{pb} = 600 \text{ Myr}$. To fractionate elements of low D_i , such as Th and U, F must be small and of the order of D_i . Where $\bar{t}_i$ approaches the age of the Earth, elements will not have achieved a steady state. Elements of lowest D_i may be present in the steady state in proportions similar or identical to the input material depending on F .

centrations. Some of the ramifications of buffering by entrainment of lower mantle material are best explored within the context of a very simple model (Fig. 3) which uses several simplifying assumptions: (1) material from the lower mantle enters the upper mantle by bulk entrainment at their mutual interface without element fractionation; (2) incompatible elements in the upper mantle are transported into the overlying lithosphere and atmosphere which, as a first step, involves the generation of a small fraction of partial melt, causing element fractionations that can be modelled as Rayleigh melting; (3) the mass of the upper mantle has remained constant, with a return flux to the lower mantle during entrainment; (4) the lower mantle can be treated as an infinite reservoir with primordial mantle (bulk Earth minus core) trace-element abundances; (5) the system has reached a steady state. Note, however, that scenarios involving a variable upper mantle mass with time¹⁻⁴ have not been explored here but are equally compatible with the geochemical evidence.

The steady-state concentration [c_1], of an element of interest in the upper mantle compared with its input value [c_0], can be shown to be

$$R_i = [c_1/c_0] = 1/[1 + (\dot{m}_2/\dot{m}_1)(f_i - 1)]$$

and its residence time is

$$\bar{t}_i = R_i/\dot{m}_1$$

where $\dot{m}_1$ and $\dot{m}_2$ are the bulk mass fluxes shown in Fig. 3 expressed relative to the total mass of the upper mantle. f_i is an enrichment factor relating [c_2], to [c_1], during partial fusion³¹.

$$f_i = [c_2/c_1] = \{1 - [1 - F]^{1/D_i}\}/F$$

where D_i is the bulk distribution coefficient during melting and F is the melt fraction involved. The melt fraction F describes in a simple manner the complex extraction of elements from the mantle into the continental lithosphere. To produce the observed element fractionations F must be $\approx D_i$. An important parameter for the upper mantle is the integrated bulk flux across its lower boundary over geological time (ϕ_m). This is readily obtainable, as $\dot{m}_1$ in the steady state is $R_i/\bar{t}_i$ which, using $R_{pb} = 0.06$ (from Fig. 2) and $\bar{t}_{pb} = 600 \text{ Myr}$, implies $\dot{m}_1 \approx 0.0001 \text{ Myr}^{-1}$, or roughly half of the mass of the upper mantle has exchanged with the lower over geological time ($\phi_m \approx 0.5$). This value will be smaller if R_{pb} is smaller (for instance, if $X_{pb} > 1$).

A processing timescale (T_p), defined as the time taken to extract

partial melt once from the upper mantle mass, is given by

$$T_p = F/\dot{m}_2 = f_i \bar{t}_i / \{1 - R_i\}$$

which is also the residence time of a perfectly incompatible element ($D_i = 0$). T_p is related to the mixing time (T_m) of the upper mantle down to a scale sampled by a basalt, but not in a straightforward manner, and is estimated at $< 600 \text{ Myr}$ as $T_m < T_p \leq \bar{t}_{pb}$. An exchange timescale (T_e) can also be defined, and is the time taken to exchange the upper mantle mass once, which is simply $1/\dot{m}_1$.

The behaviour of the system is illustrated in Fig. 4, where the concentration ratio R_i and the residence time $\bar{t}_i$ are shown as a function of D_i for various values of F , fixing $\dot{m}_1 = 0.0002 \text{ Myr}^{-1}$, $\bar{t}_{pb} = 600 \text{ Myr}$ and $D_{pb} = 0.007$. The D_i/F ratio divides elements into three groups with contrasting behaviour. First, for $D_i/F \gg 1$, $\bar{t}_i >$ the age of the Earth and so a steady-state R_i does not pertain; second, for $D_i/F = 1$, $\bar{t}_i$ and R_i are at steady state and depend strongly on D_i but not F ; and third, for $D_i/F < 1$, constant $\bar{t}_i \approx T_p$ and $R_i \approx T_p \dot{m}_1$ (independent of D_i) result from the supply of material being rate limiting. For the time-dependent (non-steady state) case it can be shown that the concentration ratio decays exponentially to the steady-state value R_i in a characteristic time equal to $\bar{t}_i$.

Consideration of this simple model suggests that the more compatible elements ($D_i > 0.1$), for example, the heavy rare-earth elements (HREE), are unlikely to have reached steady-state concentrations in the upper mantle. Furthermore, the highly incompatible elements may be uniformly extracted over the upper mantle processing time (T_p) consistent with the observation that the abundance ratios of Cs, Rb and Ba (all with $D_i < 0.001$) are nearly constant in MORB³².

For those elements at steady state, input and output fluxes are necessarily equal, for example, the Th/U ratio of both the input and output materials should be 3.9 even though the steady-state ratio is 2.5. The material that is extracted from the upper mantle to reside ultimately in the continental lithosphere must be characterized by a Th/U ratio of 3.9 that should, in principle, identify the egress route. The Th/U ratios measured in MORB glasses¹⁵ are mostly < 3.0 , and tholeiitic series basalts from oceanic island arcs are commonly even lower³³; the fractionation of Th/U required does not seem to occur in either of these environments. This is analogous to the problem of the site of the $\sim 40\%$ reduction in the Sm/Nd ratio that accompanies the production of continental crust and should be addressed in any model of mantle chemistry, whether steady state or otherwise. Only calc-alkaline series island arc volcanics have Th/U and Sm/Nd ratios³³ in the range of continental crustal materials, and the problem of Th-U and rare-earth fractionation may be linked to their genesis. The present production rate of oceanic island arc volcanics³⁴ and their abundances of highly incompatible elements³³ appear comparable with that required to balance the fluxes of these elements into the upper mantle in the steady state.

Mantle chemistry and convection

The isotope compositions and abundances of the incompatible trace elements in mantle-derived materials have been exploited to constrain theories of basalt petrogenesis, delimit the major geochemical reservoirs and their interactions and appraise the possibilities of layered versus whole-mantle convection. The observation that those trace elements with particularly small distribution coefficients ($D_i < 1$) have $\bar{t}_i \approx 600 \text{ Myr}$, and that $\bar{t}_i$ varies with D_i , has important implications for the interpretation of element and isotope abundances in mantle-derived melts.

Correlations between the radiogenic isotopes of Sr, Nd, Hf, Pb and the rare gases have been a focal point of mantle geochemistry. It is now clear that only in those instances where the residence times of the isotopes of interest are the same (such as for two of the three Pb isotope systems) is their relationship likely to be straightforward. Where $\bar{t}_i$ values differ, as between He and Sr, a large degree of decoupling of their isotope compositions is to be expected, and this is exactly what is observed³⁵.

The significance of the well-documented correlations between Pb and Sr isotopes in MORB^{24,36}, and the Nd and Sr isotopes in oceanic basalts as a whole³⁷, should be re-evaluated in view of the available constraints on their residence times.

The relationships between D_i and steady-state concentration require that the layering in the mantle, as reflected in the concentration gradients across the boundary, would be most evident for those elements with the lowest D_i (such as Pb, Th, U, K, He and Ar) and progressively less perceptible as D_i increases to 1.0, whereas the opposite would be true for isotope gradients. Furthermore, that the lower mantle reservoir is mainly responsible for the supply of short t_i elements to the upper mantle must imply that they have been retained within this layer for the whole of Earth's history. The observation that most MORB have Pb isotopic compositions not far removed from that implied for a simple closed system over the age of the Earth (the geochron) is easily explained on this basis.

The small dispersion of κ_{Th} in MORB of 2.5 ± 0.2 (Table 1) when compared with the assumed bulk Earth input value of 3.9 indicates that the introduced Th has become exceedingly well-mixed into the upper mantle by the time that such Th is sampled at spreading ridge axes. The time required to mix the length-scale of input material down to the scale of sampling at ridges is, therefore, less than the residence time of Th in the system, that is a few hundred million years, and agrees with estimates from convection experiments in a layered mantle^{38,39}. Moreover, the islands such as Hawaii and Iceland that are considered, on the basis of high $^3He/^4He$ ratios, to lie over deep seated plume structures in the mantle have $\kappa_{Th} = 3.0 \pm 0.2$ indicating that entrained material is not exclusively sampled at these islands, but a considerable portion of depleted mantle is also included.

The implied short t_i values for the heat-producing elements K, Th and U has important consequences for the early thermal history of the Earth. It can be expected that these elements were rapidly concentrated, if not stabilized, in the outermost portion of the Earth (like the Moon) within the first few hundred million years of the planet's history; a significant fraction of the Earth's radiogenic heat production would, as a result, have been highly localized from earliest times. This partitioning of highly incompatible elements may have been unrelated to the formation of continental crust, a phenomenon that essentially involves major elements, and the fractionation history of Th/Pb and U/Pb recorded by the isotope structure in the continents may conceivably predate the formation of continental crust *per se*. In the case of the Moon, the large concentrations of incompatible elements in components of the lunar crust⁴⁰ do not necessarily imply that there was accompanying large-scale major element differentiation of the interior.

Diversity and structure of genes of the α family of mouse T-cell antigen receptor

Bernhard Arden, Joan L. Klotz*, Gerald Siu & Leroy E. Hood

Division of Biology, California Institute of Technology, Pasadena, California 91125, USA

* Division of Cytogenetics, City of Hope Medical Center, Duarte, California 91010, USA

We have analysed 19 complementary DNA clones encoding the α -chain of the T-cell antigen receptor derived from thymic transcripts, and find that 15 of them contain partial or complete variable (V_α) genes. Seven of these genes cross-hybridize to over 40 germline V_α gene segments in Southern blot analyses. Of the 19 joining (J_α) sequences examined, 18 seem to be encoded by distinct gene segments, hence the repertoire of J_α gene segments is much larger than those of the immunoglobulin or T-cell receptor β -chain gene families. We suggest that the variable domains of immunoglobulins and T-cell antigen receptors are similar in structure.

THE antigen-specific receptors on T cells, like the immunoglobulin molecules used as antigen-specific receptors on B cells, can recognize and bind an almost unlimited range of antigenic determinants. T-cell antigen recognition differs from immunoglobulin antigen recognition in that it occurs only in the context of another cell-surface protein encoded by the major histocompatibility complex (MHC), a property termed MHC restriction (for review, see ref. 1). This unique property raises the question of whether the structures of T-cell antigen receptors fundamentally differ from those of immunoglobulins.

The T-cell receptor is a disulphide-bridged heterodimer composed of α - and β -chains, each divided into variable (V) and constant (C) regions²⁻⁴. Studies of the structure and organization of β -chain gene elements have revealed that the V region of the β -chain, like that of the immunoglobulin heavy (H) chain, is encoded by three separate germline gene segments, V_β , diversity (D_β) and joining (J_β), that rearrange during T-cell differentiation to form a functional V_β gene^{5,6}. There are two closely linked C_β genes, $C_\beta 1$ and $C_\beta 2$, each associated with a cluster of six functional J_β gene segments^{5,7,8}. Each J_β cluster has one D_β gene segment located ~500-700 nucleotides upstream^{9,10}.

T and B cells use several mechanisms to generate diversity in the antigen-binding V region: (1) germline diversity. Both T and B cells use many different germline V, D and J gene segments to form a V gene. (2) Combinatorial joining. Each D gene segment seems capable of joining to any downstream J gene segment, and any V may join to any D-J combination^{11,12}. (3) Somatic mutation. The V_β genes share two somatic mutational mechanisms with their immunoglobulin counterparts. First, there is flexibility in the sites at which the gene segments are joined and this generates diversity in the junctional regions^{9,10}. Second, random nucleotides may be added to either side of the D gene segments during its joining to the V and J gene segments^{9,10}, a mechanism denoted N-region diversification¹³. Immunoglobulin V-region genes may undergo somatic hypermutation at a late stage of B-cell development, a phenomenon that has not been seen in most V_β genes^{5,11,12,14}.

The V_β gene segments differ strikingly from their immunoglobulin κ and H-chain homologues in subfamily organization. A subfamily is defined as those V gene segments that are 75% or more similar to one another at the nucleic acid level and hence cross-hybridize in Southern blots under stringent hybridization conditions¹⁵. The immunoglobulin V subfamilies are composed of 4-50 or more members¹⁵⁻¹⁷. In contrast, the known mouse V_β gene segments represent eight subfamilies, six with only one member, one with two members, and one with three members^{11,12}.

Recently, mouse cDNA clones of α -chain transcripts have been described^{18,19}. The α -chains seem to consist of V, J and C regions. Here we present the sequences of 19 additional α -cDNA clones. Analyses of these 21 α -cDNA sequences reveal that: (1) the V_α gene segments are derived from at least 10 subfamilies

each containing 1-10 members; (2) there are many J_α gene segments; (3) the diversification mechanisms for V_α genes are similar to those seen for β -chain and immunoglobulin genes; and (4) the general structure of the α -polypeptides resembles that of immunoglobulin and β -chains in primary and secondary structural characteristics.

Sequences of α -cDNA clones

Nineteen cDNA clones were isolated from a thymic library of inbred C57BL/Ka mice¹¹ using a C_α probe²⁰. The cDNA inserts were subcloned into the M13mp18 bacteriophage vector and the sequences determined using the specific-primer-directed dideoxynucleotide sequencing technique (Fig. 1)²¹. Four of the 19 α -cDNA clones (TA38, TA91, TA45 and TA20) do not have a recognizable V_α gene segment (see below); 17 contain J_α sequences; and 15 contain complete or partial V_α sequences (Figs 1, 2). The α -cDNA sequences in Fig. 1 are divided into leader, V, J and C regions according to their similarities to the V and J segments of immunoglobulins and β -chains. The V_α segment is ~90 residues long and has a leader of 19-22 amino acids (Fig. 1). The N-terminal amino acid of the mature V_α gene product is presumed to be 22 or 23 residues from the first conserved half-cysteine residue according to the general rules that have been deduced for determining the leader peptide cleavage site²². The 3' ends of the V_α sequences have been provisionally designated as the same length as that of a single germline gene segment, $V_\alpha 5H$, a member of the $V_\alpha 1$ subfamily, analysed by Winoto *et al.* in the accompanying paper²⁰. The 5' and 3' ends of four J sequences have been determined by sequence analysis of four germline J_α gene segments (TA84, TA19, TA65 and TA80)²⁰. The boundaries of the remaining J_α sequences were provisionally assigned by homology (see Fig. 1 legend). There are nucleotides present between the V_α and J_α sequences that might arise from various different sources (see ref. 20).

Subfamilies of V_α gene segments

The amino-acid sequences of the 15 V_α segments were aligned with one another and with two additional V_α segments from the literature, TT11 (ref. 18) and pHDS58 (ref. 19) (Fig. 2). The V_α segments can be divided into 10 different subfamilies, members of each subfamily being 75% or more homologous with one another at the DNA level. The V_α segments from different subfamilies are 20-54% similar to one another at the protein level (Table 1). This range of homologies is similar to that observed between the V_β and immunoglobulin V_H subfamilies¹¹. We have denoted these subfamilies as $V_\alpha 1$ to $V_\alpha 10$ (Fig. 2). Five of these subfamilies ($V_\alpha 1-5$) are represented by two members and five by only one.

To estimate the number of germline V_α gene segments in each subfamily, Southern blot analyses were performed on liver DNA from four different inbred strains of mice using V_α -containing

Fig. 1 Nucleotide sequences of 19 α -cDNA clones derived from the thymus. The leader (L), V, J and C regions are indicated. Clones TA38, TA91 and TA45 do not contain V_{α} sequences. The dotted lines between the V and J regions indicate junctional diversity arising from any one of several mechanisms (see ref. 20). The 3' ends of the V_{α} gene segments were arbitrarily chosen to be identical with the end of the germline $V_{\alpha}5H$ gene segment²⁰. The 5' ends of the J_{α} gene segments were determined by comparison with the corresponding germline J_{α} gene segments (indicated by asterisks)²⁰ or by arbitrarily assuming that the J_{α} gene segment begins one codon after the end of the V_{α} gene segment. Assignments of the 5' ends of the J_{α} gene segments for the TA31 and TA27 cDNA clones are complicated by the presence of frameshift mutations at the junctional regions. Gaps are inserted to maximize similarity. The arrow at base 429 indicates diversity at the end of the J_{α} gene segment (see text). In clone TA45, the recognition sequences for DNA rearrangement are boxed. A 500-bp *Sau3A1* restriction fragment containing the C_{α} gene was used as a ³²P-labelled, nick-translated probe³⁷ to screen a λ gt10 cDNA library constructed from C57BL/Ka thymus messenger RNA (ref. 38, modified by Barth *et al.*¹¹). The cDNA inserts from C_{α} -containing clones were subcloned into the M13mp18 vector³⁹. The subclones were sequenced using the specific-primer-directed dideoxynucleotide chain termination method²¹. Synthetic oligonucleotide probes complementary to both strands of the C_{α} gene were used to select inserts of both orientations.

Fig. 2 Protein sequences of 17 V_{α} gene segments. Clone designations (left) and V_{α} subfamily designations (right) are given. Dots indicate that the sequence is identical to that of clone TT11. The blanks indicate sequence gaps introduced to maximize homology. The asterisks indicate residues that are relatively conserved in V_H , V_L , V_B and V_{α} regions.

Fig. 3 Southern blot analysis of mouse germline DNA with complete α -cDNA clones from seven V_{α} subfamilies. Liver DNA from four inbred strains of mice was isolated⁴⁰ and *Bam*HI-digested. Similar results were obtained using liver DNA digested with *Eco*RI and *Hind*III (not shown). The 9.8-kilobase C_{α} -hybridizing bands on each filter have been aligned here and are indicated by an arrow. As the DNA migration distances varied slightly from gel to gel, hybridizing bands at the same location on different filters do not necessarily contain DNA fragments of precisely the same size. Each DNA digest (10 μ g) was electrophoresed on 0.7% horizontal agarose gels and transferred to nitrocellulose⁴¹. Hybridizations were for 24 h at 37 °C in 50% formamide, 0.8 M NaCl, 0.1 M Tris pH 7.5, 5 $\times$ Denhardt's, 100 μ g ml⁻¹ denatured salmon sperm DNA, 10% dextran sulphate and 0.5 μ g ³²P-labelled nick-translated cDNA probe. Filters were washed at 68 °C with 1 $\times$ SSC containing 0.1% SDS.

*Eco*RI fragments as probes (Fig. 3). Because some of the α -cDNAs contain only a small segment of V_{α} sequence (Fig. 1), only seven of the V_{α} subfamilies were analysed. Assuming that each distinct band represents at least one separate V_{α} gene segment, the V_{α} subfamilies analysed here range in size from 1 to 10 members, and the minimum number of bands identified for all seven subfamilies is 40. This distribution is similar to that seen in the immunoglobulin κ - and H-chain gene families and contrasts with the V_{β} gene family, where six of eight subfamilies analysed contained just one member, and the total V_{β} repertoire is believed to be <21 members^{11,12}.

Three identical V_{α} sequences have been observed to be associated with three distinct J_{α} segments, a surprising result for which we can offer no explanation apart from the possibility that rearrangement and expression of this V_{α} sequence may be preferred in the thymus. The remaining 12 V_{α} sequences are all distinct from one another (Fig. 2).

Restriction length polymorphism is observed between inbred C57BL/6J mice and the three other strains of mice analysed (Fig. 3). Differences are seen with all seven V_{α} probes. In addition, some subfamilies in different mouse strains appear to differ in their V_{α} gene segment numbers; for example, compare the C57BL/6J strain with the others (Fig. 3). The immunoglobulin H- and κ -chain gene families also exhibit extensive restriction length polymorphism, whereas the V_{β} gene family shows very limited polymorphism. Variation in band number within particular subfamilies probably represents the duplication and/or deletion of V_{α} gene segments in the various inbred strains of mice. These data are consistent with the hypothesis that multi-membered V subfamilies may undergo gene expansion and contraction by homologous but unequal crossing-over (see ref. 11).

Numerous J_{α} segments

Of the 17 J_{α} sequences described in this paper and two from the literature^{18,19}, 18 different J_{α} sequences have been identified (Fig. 4). As we found only one repeat, the repertoire of J_{α} gene

segments is probably much larger than 18. We believe that each of these different sequences represents a distinct germline J_{α} gene segment as they differ considerably from one another in sequence. The J_{α} segments exhibit a range of similarity at the protein level (32–72%) comparable with that for J_{β} segments (33–75%) and somewhat lower than that seen for J_{κ} (55–85%), J_H (57–80%) and J_{λ} (70–85%) segments. The J_{α} gene segment repertoire is larger than those of the β -chain (12) or immunoglobulin (4–5) genes. The large repertoire and diversity of the J_{α} gene segments may have important implications for antigen/MHC recognition, as the J segments in immunoglobulins usually fold to form a contact point of the antigen-binding site.

Nonproductive thymic V_{α} transcripts

Nonproductive α -cDNAs may arise by joining events which place the J gene segment in an improper translational reading frame with respect to the V gene segment, by rearrangement of a pseudogene segment or by initiation of transcription 5' to a germline J gene segment or 5' to an incomplete D–J rearrangement. Of the 15 α -cDNAs that have V_{α} gene segments, 5 seem to be derived from nonproductive transcripts. Three of these may have resulted from the rearrangement of a pseudogene. One clone, TA37, has a frameshift within the V_{α} gene segment caused by a single nucleotide deletion at position 317 (Fig. 1). The TA80 clone seems to have a base substitution that has changed the cysteine residue at position 22 to alanine (Fig. 2). This cysteine residue is invariant in immunoglobulins and β -chains and is believed to be important for stabilizing the V domain structure. In addition, the V_{α} and J_{α} gene segments have joined so that the J_{α} gene segment is out of the proper translational reading frame. Thus the TA37 and TA80 clones probably represent transcripts derived from the rearrangement of pseudogenes. A third clone, TA26, has a V_{α} gene segment virtually identical to the previously published pHDS58 V_{α} gene¹⁹ apart from a large deletion in the centre of the V_{α} region encompassing 43 residues and creating a translational frame-

shift. Two base changes within the coding region do not lead to changes in amino-acid sequence from the pHDS58 V_α segment and might represent polymorphism between the inbred BALB/c and C57BL/Ka mice. The TA26 V_α gene segment may be a pseudogene that has been rearranged and transcribed (see ref. 23), or alternatively the deletion could represent a cloning artefact. Finally, the TA27 and TA31 clones also contain a V_α - J_α junction which shifts the J_α sequence out of the correct translational reading frame. Nonproductive rearrangements of this type have been reported previously for both immunoglobulin²⁴ and T-cell receptor β -chain genes (M. Malissen, unpublished data) and are often transcribed²⁵. The remaining 10 V_α -containing clones seem to represent productive or functional V_α - J_α rearrangements, although we cannot exclude the possibility that one or more of the partial V_α sequences have mutations in their unsequenced regions that would cause them to be pseudogenes.

α -cDNA clones lacking V_α

Of the 19 cDNA clones analysed, 4 did not contain V_α sequences. One clone, TA20, extends only into the 5' half of a J_α gene segment. A second, TA45, seems to be either a germline J_α transcript or a transcript from an incomplete D - J rearrangement. Both of these transcription events are known to occur in β -chain genes^{9,26}. The TA45 clone contains a J_α sequence and a 5' recognition sequence for DNA rearrangement, consisting of a conserved heptamer, a spacer sequence of 12 nucleotides and an A/T-rich nonamer. The germline V_α gene segment has the rearrangement recognition sequence with a 23-base-pair (bp) spacer²⁰. In immunoglobulin and β -chain genes, gene-segment rearrangements always occur between recognition sequences with 12- (one turn of the DNA helix) and 23-bp (two turns) spacers^{5,6,27,28}. Hence, this one-turn recognition sequence can join to the two-turn recognition sequences of the V_α genes²⁰. As the germline sequence of this J_α gene segment has not been determined, we do not know whether the recognition sequence lies to the 5' side of a D_α or a J_α gene segment. Finally, two of the cDNA clones encode complete C_α , but no J_α or V_α regions. The sequences to the 5' side of the C_α genes are not similar to each other or to the intron sequences flanking the germline C_α gene (A. Winoto, unpublished data). Presumably, these cDNA clones represent aberrant RNA splicing events.

V_α gene diversification mechanisms

The α -chain genes apply three mechanisms used by the immunoglobulin and β -chain genes for diversification.

Germline. Southern blot analyses with V_α probes and the V_α sequence analyses suggest that at least 10 different V_α subfamilies exist which encode >40 V_α gene segments. Only one V_α sequence is repeated in the sample of cDNAs analysed. A comparable analysis of 22 V_β sequences revealed 11 repeat V_β sequences and only 13 distinct V_β gene segments¹¹. Statistical analyses of thymus β -chain cDNA clones indicate that there are ≤ 21 germline V_β gene segments¹¹ and perhaps only two D_β gene segments^{11,14}. Hence the diversity of the V_α gene segment repertoire seems to be considerably larger than that of the V_β gene segments. The germline J_α repertoire seems to be quite large in that 18 out of 19 sequences sampled are different. This J_α diversity greatly increases the germline diversity at the carboxy-terminal end of the V_α region. Although provisional alignments of the different α -cDNA clones with the available germline V_α and J_α sequences reveal additional nucleotides at the V - J junctions (Fig. 1), additional germline α -sequences will have to be determined before the existence of D_α gene segments can be established (see ref. 20).

Combinatorial joining. Two examples of combinatorial joining in the α -family have been observed in the sample of α -cDNA sequences examined. First, the same V_α sequence in clones TA84, 46 and 31 has been joined to three distinct J_α gene segments (Fig. 1). Similarly, the same J_α sequence has been joined to two distinct V_α gene segments (TA28 and A. Winoto, unpublished data). Therefore, the combinatorial joining of V_α and J_α gene segments can occur in the α -family.

Fig. 4 Protein sequences of J_α segments. The N- and C-terminal boundaries of these sequences have been approximated using the germline sequences of six J_α gene segments²⁰. Asterisks indicate amino acids conserved in the J_α , J_β , J_H and J_L regions. Dots indicate identity to the TT11 sequence. Gaps are inserted to maximize similarity. The boundaries of the remaining J_α regions were provisionally assigned to the second residue following the putative C-terminal end encoded by the V segment. Diversity in the C-terminal residue is generated by RNA splicing (see text).

Fig. 5 Variability plot of V_α regions. Variability was determined according to the method of Wu and Kabat³¹. Nine V_α segments were analysed. The variability at each amino-acid position N is calculated as: $\text{Variability}_N = (\text{No. of different amino acids that occur at } N) / (\text{Frequency of most common amino acid at } N)$. For comparison, the first and second hypervariable regions of V_H segments are indicated.

Somatic mutation. The delineation of junctional and N-region diversification mechanisms requires a comparison between germline and rearranged V_α sequences. These mechanisms are used in the V_α gene family, as demonstrated in the accompanying paper²⁰. The fact that three V_α gene segments are identical to one another suggests that somatic hypermutation has not occurred in these α -chain genes. However, somatic hypermutation occurs late in B-cell development. Here we are analysing antigen-receptor genes at an early stage of T-lymphocyte development, possibly before somatic hypermutation. Data on the receptors of mature T cells will be necessary to determine whether somatic mutation does occur in V_α genes.

Diversification of a special type occurs at the J_α - C_α boundary. The last nucleotide in the J_α gene segments may be any of the four bases (Figs 1, 4). In the immunoglobulin and β -chain gene families the final nucleotide of the J gene segment is invariant. As RNA splicing joins the last nucleotide of the J gene segment to the first two nucleotides of the C gene, four different junctional codons are generated at the J_α - C_α junction: asparagine (AAC), histidine (CAC), aspartic acid (GAC), and tyrosine (TAC). It will be interesting to determine whether this boundary

diversity has any functional significance for the T-cell antigen-binding receptor.

Structure of the V_{α} region

We have analysed the primary and secondary structures of the V_{α} regions to determine whether they resemble the V regions of β -chains and immunoglobulins.

Both the V_{α} and V_{β} regions share many conserved residues with both the V_H and variable light-chain (V_L) regions of immunoglobulins, including 14 residues in the V and 4 residues in the J regions (marked by asterisks in Figs 2, 4). An analysis of the three-dimensional structures of the V domains in several immunoglobulin molecules demonstrates that there are many highly conserved residues important for stabilization of V_L - V_H interactions and for intrachain V_L or V_H interactions^{29,30}. Most of these residues are conserved in the V_{α} and V_{β} regions.

Another approach to elucidate primary structural patterns in the T-cell receptor and immunoglobulin V regions is the variability plot of Wu and Kabat³¹; this analysis examines the distribution of variation of each residue position between members of a set of similar sequences. In immunoglobulin and β -chain V regions, two regions of relative hypervariability are noted, with

a third hypervariability³¹ region positioned at the junction of the V, D and J gene segments^{11,32}. A variability plot of the V_{α} sequences does not differ dramatically from the V_H and V_{β} variability plots (Fig. 5 and refs 11, 12). With the limited number of V_{α} sequences analysed, one must be cautious in drawing generalizations for the overall variability in this set is high. However, the regions corresponding to the two classically defined hypervariable regions (residues 30–35 and 51–60) seem to have increased variability. We note two additional areas of hypervariability (residues 8–9 and 66–71) but feel their existence is uncertain until more V_{α} -sequences are available for analysis. The junction of the V_{α} and J_{α} segments generates an additional hypervariable region (not shown).

Two further analyses have been conducted on the V_{α} sequences to assess the nature of their secondary structure. The Kyte-Doolittle hydrophobicity profile³³ plots the distribution of the relative hydrophobicities of the amino-acid side chains of a particular protein. The Chou-Fasman method^{34,35} determines the relative potential for β -pleated sheet formation. Both these analyses measure properties that are thought to reflect important secondary structural features of the protein. The Kyte-Doolittle hydrophobicity and the Chou-Fasman plots of the V_{α} , V_{β} , V_H and V_{κ} (not shown) sequences are very similar (Fig. 6). The plots represent averages of multiple sequences to minimize unusual individual variations. These data indicate that the secondary structures of the V_{α} , V_{β} , V_H and V_{κ} regions are similar to each other.

Thus, several lines of evidence suggest that general primary and secondary structural features are conserved in the V_{α} , V_{β} , V_H and V_{κ} regions: (1) they share highly conserved amino-acid residues, most of which are important for stabilization of the highly conserved immunoglobulin fold; (2) the variability plots demonstrate variability consistent with three hypervariable regions; and (3) the hydrophobicity and Chou-Fasman plots suggest similar potential for β -pleated sheet formation. These data suggest that the T-cell antigen receptor and immunoglobulin molecules have similar structure. Moreover, as immunoglobulins may also be MHC-restricted³⁶, it is unnecessary to postulate any special sites, apart from the classical antigen-binding site, for binding properties of T-cell MHC-restricted antigen receptors.

We thank Debbie Maloney and Marty Garcia for technical assistance, Marilyn Tomich and Dr Suzanna Horvath for the synthetic oligonucleotide used in the DNA sequencing, Drs Howard Gershenfeld, Craig Okada and Irving Weissman for the thymocyte cDNA library, Drs Richard Barth, Byung Kim, Joan Kobori, Mitchell Kronenberg, Ulf Landegren, Nilabh Shastri, Martha Zuniga, Tim Hunkapiller and Astar Winoto for critical comments on the manuscript, and Bertha Jones, Gwen Anastasi and Susan Mangrum for help in preparing the manuscript. This work was supported by grants from the NIH, T Cell Sciences Inc., the State of California Department of Health Services (to J.L.K.) and the Deutsche Forschungsgemeinschaft (to B.A.).

The most complete early hominid skeleton ever found was discovered at Nariokotome III, west Lake Turkana, Kenya, and excavated in situ in sediments dated close to 1.6 Myr. The specimen, KNM-WT 15000, is a male Homo erectus that died at 12 ± 1 years of age, as judged by human standards, but was already 1.68 m tall. Although human-like in many respects, this specimen documents important anatomical differences between H. erectus and modern humans for the first time.

DURING the course of palaeontological exploration on the west side of Lake Turkana, Bw. Kamoya Kimeu found a small fragment of hominid frontal bone exposed on the surface at the site of Nariokotome III, on the south bank of the Nariokotome River. The approximate latitude and longitude of the site are $4^{\circ}08' \text{ N}$, $35^{\circ}54' \text{ E}$ (Fig. 1). Near the site the Plio-Pleistocene beds strike $\text{N } 7^{\circ} \text{ E}$ and dip 5° to the west. Exposures are reasonably good along the south bank of the Nariokotome where a section was measured to establish the stratigraphic position of the hominid (Fig. 2). Several tuffs occur within this section that have been correlated with tuffs elsewhere in the Turkana Basin on the basis of their chemical composition. The hominid derives from a siltstone that immediately overlies a tuff identified as a component ash of the Okote Tuff complex of the Koobi Fora Formation. The age of this tuff is $\sim 1.65 \text{ Myr}^{1,2}$. An ash that correlates with Tuff L of the Shungura Formation (Chari Tuff of the Koobi Fora Formation) dated at $1.39 \text{ Myr}^{3,4}$ lies 34 m above the hominid level. An un-named tuff dated at 1.33 Myr^4 lies 46 m above the specimen. Thus, the hominid is probably very close to 1.6 Myr in age.

The strata consist predominantly of pale yellowish-brown sandstones and siltstones and very pale yellowish-brown to medium-brown siltstones. The sandstones and siltstones are either laminated or massive. The tuff that underlies the hominid fills cracks in an underlying sandy siltstone and contains small-to-medium-scale trough crossbeds truncated at their tops and overlain by siltstone. A small lens of fine tuffaceous sand that lies $\sim 1 \text{ m}$ above the hominid level contains abundant amphioxea and amphistrongyla of freshwater sponges. A tuff that lies 6.7 m above the hominid level contains reworked molluscs at the base and a sandstone 13.8 m above the hominid is capped by an ostracod-rich layer 10 cm thick. Mammalian fossils are rare at this locality, the most abundant vertebrate fossils being parts of small and large fish. The depositional environment was evidently an alluvial plain of low relief, consistent with the fossil fauna in the section. It is likely that the plain was only slightly higher in elevation than a lake which existed nearby, such that with only minor changes in lake level, typical lacustrine forms (for example, ostracods, molluscs) could invade the area.

Twenty-five other vertebrate-bearing sites were located and collected during the 1984 season. Individual sites were labelled by the name of the ephemeral river draining their exposures and were further numbered sequentially in order of their discovery (Table 1). As at Koobi Fora, the Okote Tuff was used as a marker horizon in the subdivision of the fossiliferous succession. Fossil assemblages were retrieved from horizons a short depth below the Okote Tuff at five localities and slightly above it at eight localities (see Table 2). Appreciably fewer taxa are represented at these new localities than at equivalent places at Koobi Fora, but this may be an artefact of sample size. The distribution of identifiable species at sites on both sides of the lake, specifically the presence of *Deinotherium bozasi*, *Elephas recki ileretensis*, *Diceros bicornis*, *Metridiochoerus andrewsi* and

Fig. 1 Map of northern Kenya to show location of site Nariokotome III.

Gazella janenschi only at horizons below the Okote tuff and *Metridiochoerus compactus* only at horizons above this tuff, provides a measure of correlative support for geochemical analyses of the tephra. *Tragelaphus scriptus* is the only species from this part of the section on the west side of the lake that is not represented yet at Koobi Fora.

Following the initial discovery, screening and washing of surface float and pebble lag led to the recovery of most of the hominid calvaria. The facial skeleton was found just eroding out from tuffaceous sediments. Excavation of an area $\sim 5 \times 6 \text{ m}$ has led so far to the recovery of the mandible, several isolated teeth and much of the postcranial skeleton. A list of the parts found so far is given in Table 3. The site plan of the excavation (Fig. 3) shows that the skeleton was dispersed before final sedimentary burial. The bones were found in a layer of tuffaceous silt of variable thickness deposited on a more indurated, flat-lying tuffaceous sand with orange root casts. The top of the fossiliferous horizon shows many signs of bioturbation and several of the bones were found broken or lying in positions suggesting that they had been trampled by large mammals. The

Fig. 2 Section at site Nariokotome III to show stratigraphic position of KNM-WT 15000.

general alignment of the long bones, separation of elements once in close articulation and the linear dispersal of the skeleton over at least 7 m, indicate minor water transport (see Fig. 3). Postmortem damage is seen and some parts of the bones are crushed, particularly where there is much cancellous tissue. There are no signs of carnivore or scavenger damage and the only pathology is a minor amount of alveolar resorption on the right mandibular body which took place before the right dm_2 was shed. The only other fauna found so far in the fossiliferous bed are many opercula of the swamp snail *Pila*, a few bones of the catfish *Synodontis* and two fragments of indeterminate large mammal bone, although equid and pygmy hippopotamus remains were found on the surface here.

The cranium has been assembled from about 70 pieces. The only main pieces missing are the nasals, ethmoid, lacrimals, central parts of the supraorbital tori, parts of the sphenoid and some parts of the vault, the two largest being bits of the right frontal near bregma and right parietal near lambda. The sutures were all unfused. The facial skeleton was positioned on the braincase by using the mandible. The mandible is undistorted, but the calvaria has a slight overall plastic deformation with the upper part displaced to the left. Only a preliminary cranial reconstruction has been possible so far and the capacity has not been measured. Table 4 lists the teeth found so far and their measurements. They are all close to the mean size recorded for *Homo erectus* from Zhoukoudian⁵. The M3 germs will have to be examined radiologically. Several of the teeth were excavated separately and returned to their alveoli. The alveoli for the deciduous upper canines are still visible lateral to the permanent canine alveoli, and the left upper canine was in the process of erupting. The degree of root development of the isolated teeth, the tooth wear stages and the eruption stage are equivalent to that in 12 ± 1 -year-old modern human males⁶. The canines erupted later than the M2s, and although this is not usual, it is a known human condition⁷. The dental age is matched in the postcranial skeleton where all epiphyses are unfused and the incongruity between growth-plate surfaces suggests that much further growth would have been possible. The cranium does not show strong tori, temporal or nuchal lines because it was immature at death. Despite this, its tori are thicker, its palate broader and its facial skeleton bigger and more massive than those of the presumed female cranium KNM-ER 3733 (ref. 8), which is from a roughly equivalent time horizon in the same basin. We take this to mean that there was probably considerable sexual dimorphism in the crania of early *H. erectus*. It is conceivable that this individual, had it lived to maturity, might have developed as strong and robust a cranium as that of Olduvai Hominid 9 (ref. 9).

Indet., indeterminate horizon.

Previous *H. erectus* postcranial material has been either fragmentary, not definitely associated, disputed as to species or diseased. From Trinil, Indonesia¹⁰, there are several fragmentary and one complete (but pathological) femora. Despite the fact that it was these specimens that led to the species name, there are doubts as to whether they are *H. erectus*¹¹ with the most recent consensus being that they probably are not. Until recently the only *H. erectus* postcranial bones from China were from Zhoukoudian¹² and these were very fragmentary, with no complete lengths or articular surfaces. The reported clavicle is probably not even primate¹³. Recent newspaper accounts report an *H. erectus* cranium, innominate, ulna, three vertebrae, a rib; some hand and foot bones, a patella and a partial innominate from Yingkou, Liaoning Province, China, which are said to be 200,000 yr old^{14,15}.

H. erectus postcrania have also been found at Olduvai Gorge, Tanzania, and East Turkana, Kenya. An associated fragmentary left innominate and femoral shaft (OH 28) from Bed IV Olduvai have been described as belonging to this species¹⁶. Tibial and femoral shafts (OH 34) from Bed III Olduvai¹⁷ may belong, but are so badly eroded that their analytical value is slight. An undescribed ulna (OH 36) from Bed II Olduvai has also been attributed to this species¹³. There are many postcranial bones from East Turkana^{18,19}. Only one is definitely associated with complete enough cranial remains to be absolutely certain of attribution and, unfortunately, that individual had suffered from a disease which affected the postcranial skeleton^{19,20}. The East Turkana specimens are mainly isolated and/or fragmentary.

The finding of KNM-WT 15000 will allow not only the study of the morphology and proportions of this individual, but also allow firmer attributions and enhance the analytical value of very many other isolated or fragmentary specimens. Recognizing that the excavation has yet to be completed and that this will probably result in the recovery of more parts, a complete assessment of this individual will not yet be attempted. There are, however, some points which can confidently be made. The stature of the individual has been estimated by using regression equations developed on modern human adult males²¹ to be 1.68 m (caucasian) or 1.64 m (blacks). This individual would not have been quite that tall, because the cranium does not have the great height of modern *Homo sapiens*. Despite the young age of the individual, the length of the long bones are very close

to the means for white North American adult males given by Schultz in 1937 (ref. 22). We have examined casts and originals of other early *H. erectus* postcranial bones and find that all of them are large. Stini²³ noted current secular trends of increase in body size in many human populations and wondered whether the trend was revealing a genetic potential left over from early hunter and gatherer ancestors. The new *H. erectus* data support this hypothesis.

The vertebrae show some interesting differences from those of modern humans. The spinous processes on all vertebrae recovered so far are relatively longer and less inclined inferiorly than their modern counterparts and the laminae are much less broad. This means that the marked imbrication of the laminae and spines of adjacent vertebrae (particularly the thoracic series) so typical of *H. sapiens* is much less marked. The vertebral foramen is smaller relative to vertebral body size in the lower cervical and thoracic series, unlike that of modern humans, but about the same in the lumbar series. The inferior articular facets of the fifth lumbar vertebra face almost directly anteriorly and are slightly concave, in contrast to the usual human condition in which the surfaces face laterally and are cylindrically convex²⁴.

Although we have yet to recover sufficient parts of the pubic bones to complete a full reconstruction, the innominates are very similar indeed to OH 28 and KNM-ER 3228 (refs 16, 25), but the strong iliac pillar had not yet developed. The sacrum is represented by S1 and S5, the spine of S3 and half of S4. Although we can reasonably estimate the sacral width, precise alignment with the pelvis must wait for the recovery of S2. There was a remarkable degree of iliac flare²⁶; this flare is concordant with the extremely long femoral necks, which are relatively as long as those of robust australopithecines²⁶. The biomechanical advantage of the abductor mechanism²⁶ was much enhanced relative to the condition in *H. sapiens*. The biomechanical neck length of 85 mm is well over 3 s.d. from the mean of a sample of *H. sapiens*²⁶. As well as having a long femoral neck, the neck-shaft angle is very small at 110°, being 5 s.d.s from the mean of the same *H. sapiens* population. The femoral head diameter at 44.0 mm is almost exactly on an *H. sapiens* mean²⁷ and scales with femoral length in the same way as *H. sapiens* and *Australopithecus boisei*²⁸.

Martin²⁹, following a stimulating discussion of human and great ape brain growth, suggested that early *H. erectus* could

have produced their adult brain sizes by modification of the rate and/or extent of fetal growth without any need for significant postnatal postponement of fetal growth patterns as found in humans. This is dependent, however, on *H. erectus* pelvis having allowed the birth of an infant as large as those of *H. sapiens*. Modern human populations show little, if any, sexual dimorphism in the absolute width of the sacrum³⁰, a major determinant of pelvic inlet size. The interacetabular distance in WT 15000 is very small and surely correlated both with the great iliac flare and long femoral necks. It seems likely to us that early *H. erectus* birth-canal diameters would have been significantly smaller than in *H. sapiens* and that passage of a modern-sized, full-term fetus would have been impossible. The continuation after birth of fetal growth rates, found only in

humans, must have been part of the developmental mechanism of *H. erectus*. Already then, by 1.6 Myr ago, the secondarily altricial condition (which leads to increased infant dependency) must have been present.

This skeleton has already shown that our views of early

H. erectus morphology must be modified. With the possibility of finding more parts when the excavation is continued and with further analysis, KNM-WT 15000 will provide a firmer foundation for the identification and understanding of unassociated postcranial bones and early hominid growth patterns. Except for those representing the latest stages of our evolution, it is also the first fossil hominoid, let alone hominid, in which brain and body size can be measured accurately on the same individual. These two crucial variables, on which so much speculation about human origins and behaviour has been based, can now be determined for at least one individual early hominid.

LETTERS TO NATURE

Age of the Okote Tuff Complex at Koobi Fora, Kenya

Ian McDougall, T. Davies, R. Maier & R. Rudowski

Research School of Earth Sciences, Australian National University, PO Box 4, Canberra, ACT 2601, Australia

The Okote Tuff Complex crops out in the Koobi Fora region next to the north-eastern shores of Lake Turkana, northern Kenya. It occurs in the upper part of the ~450 m thick, essentially flat lying, Plio-Pleistocene sequence of fluvial, deltaic and lacustrine sediments comprising the Koobi Fora Formation¹⁻³. Many important archaeological sites and hominid fossils, including the *Homo erectus* finds discussed in the accompanying papers^{4,5}, are stratigraphically close to the level of the Okote Tuff Complex⁶ or its correlatives, so that its precise numerical age is of great interest. Previously published isotopic ages, mainly by the ⁴⁰Ar/³⁹Ar dating technique, exhibited a very wide scatter⁷. Here we report comprehensive K-Ar data showing that pumices within one of the tuffs of the Okote Tuff Complex have an age of 1.64 ± 0.03 Myr, which is in the earliest Pleistocene⁸.

The type locality for the Okote Tuff Complex is within area 131, adjacent to Karari Ridge, 20-km east of Lake Turkana (Fig. 1). The unit was formally named by Findlater² and discussed further by Cerling and Brown³. A stratigraphical section measured in this area is shown in Fig. 2, after ref. 5. The Okote Tuff Complex lies about mid-way between the KBS and Chari Tuffs which, in area 131, are separated by ~40 m of section consisting mainly of river channel sands together with some flood plain silts and clays. The Complex has yet to be defined and described in detail. In the field it consists of several sandy

Fig. 1 Outcrop of the Koobi Fora Formation adjacent to the shores of Lake Turkana is indicated by blank area. Type locality for the Okote Tuff Complex is shown by filled circle within fossil collection area 131. Local basement, dominantly Neogene volcanics, is indicated by pattern.

$\lambda_e + \lambda_c = 0.581 \times 10^{-10} \text{ yr}^{-1}$, $\lambda_\beta = 4.962 \times 10^{-10} \text{ yr}^{-1}$, $^{40}\text{K}/\text{K} = 1.167 \times 10^{-4} \text{ mol mol}^{-1}$. Mean age (excluding 81-134, 83-330) = 1.64 ± 0.03 Myr. Mass of sample used in Ar extraction in range 0.8 to 1.5 g. Locality: at coordinates 049-124 on 9 $\times$ 9-inch photographic print number 1750 taken in December 1970 by Hunting Surveys, London, where coordinates are millimetres from left edge and from the top edge of the print, respectively. Trimming of the pumices was done in the field to remove the outer centimetre or two of each clast to minimize the possibility of contamination of the samples by detrital feldspar. Some of the pumices were partly calcified. Separation of the feldspars from the pumice clasts was done, after crushing, on the >0.5 mm size fraction by water panning, followed by purification using heavy liquid and magnetic techniques. Most concentrates were washed ultrasonically for 3 min in 7% HF to help remove traces of glass adhering to the feldspar. Purity of >99% was attained. The crystals were quite unaltered and limpid, and exhibit very fine polysynthetic twinning. K and Ar were measured by flame photometry and isotope dilution, respectively. Ar extractions were made in a vacuum system by radiofrequency heating of the sample, contained in a Mo crucible, to temperatures >1,600 $^{\circ}\text{C}$ for 1 h to try to ensure full Ar recovery from the melt. After purification of the Ar, isotope analysis was carried out in a VG-Isotopes MM1200 gas-source mass spectrometer.

ryholitic tuff beds extending over ~ 16 m of section. Individual beds are generally 0.7–1.5 m thick. The tuffs were deposited from water in much the same manner as the enclosing detrital sediments.

In a small hill ~ 100 –150 m north of archaeological site FxJj20 at East African Grid HBH793592, at the type locality of the Okote Tuff Complex, rounded pumice clasts of up to ~ 20 cm in diameter are found in the upper part of a tuff bed 1.6-m thick, designated the Lower Okote Tuff⁵. A relatively large number of pumices was collected from this locality, as each contained some alkali feldspar phenocrysts, ideal for isotope dating by the conventional K-Ar method. Dating techniques used were similar to those described previously⁹.

Results on the alkali feldspar (anorthoclase) concentrates from 10 different pumice clasts are given in Table 1. Duplicate K analyses agree to better than 0.5% in most cases. Replicate Ar measurements show a spread averaging about 2%, with differences of >5% in two cases. For these two samples (81-133 and 83-331), the relatively large spread in their measured Ar contents may be because of minor but variable contamination by detrital feldspar, or because of incomplete extraction of the radiogenic Ar from some of the melts; with the available data it does not seem possible to distinguish between the alternative explanations.

The K contents of the 10 anorthoclase concentrates show a very limited spread, with a mean of 4.72 (± 0.02)%; this is good evidence that the pumice clasts were derived from a single volcanic eruption.

Eight of the alkali feldspars yielded K-Ar ages within the range 1.60–1.70 Myr, from which a mean age of 1.64 ± 0.03 Myr is calculated. The remaining two feldspars gave substantially

older apparent ages of 1.94 ± 0.02 and 2.47 ± 0.03 Myr (Table 1). These two results are clearly anomalous, probably to be explained by minor contamination of the mineral separates from old detrital feldspar incorporated within the pumice clasts.

The good agreement of the K-Ar results on eight of the feldspars, yielding a mean age of 1.64 ± 0.03 Myr, is accepted as strong evidence that this records the time of cooling of the feldspars immediately following the explosive volcanic eruption that produced the pumice clasts. Findlater¹⁰ argued that the time between explosive volcanism and deposition of the products is likely to be short in comparison with the time resolution obtainable by the K-Ar dating method. Brown and Feibel⁵ have shown, however, that the glass of the pumice clasts differs significantly in composition from that of the enclosing Lower Okote Tuff, implying that they are products of different eruptions. No tuffs in area 131 have been found that have glass of the same composition as that of the pumices, although a good match is obtained with tuff J4 in the Shungura Formation. As pumice clasts are likely to have been transported by floating¹¹, reworking and final incorporation into younger sediments is a reasonable explanation for their present location. Thus 1.64 ± 0.03 Myr must be the maximum age for deposition of the enclosing Lower Okote Tuff.

This limiting age for a tuff in the lower part of the Okote Tuff Complex is intermediate between that obtained for the Chari Tuff (1.39 ± 0.02 Myr; ref. 12) higher up the sequence, and the age of 1.88 ± 0.02 Myr (refs 9, 12, 13) found for the KBS Tuff ~ 16 m below, consistent with the stratigraphical position of the Okote Tuff Complex in the sequence.

The KBS Tuff and immediately adjacent sediments are normally magnetized, whereas the overlying sediments, including

Fig. 2 Stratigraphical section through part of the Koobi Fora Formation in area 131, adjacent to Karari Ridge, after ref. 5. Pumice clasts dated in this study were collected from the Lower Okote Tuff, indicated by the symbol on the section ~17 m above the base.

the Okote Tuff Complex, are of reverse polarity^{14,15}. The palaeomagnetic and age data, therefore, are consistent with deposition of the sequence during the Matuyama reverse chron, the sediments at the KBS Tuff level having been laid down during the Olduvai normal subchron¹⁶.

In the Ileret area and adjacent to Koobi Fora spit (Fig. 1), tuffaceous beds also occur above the KBS Tuff in a stratigraphical position similar to that of the Okote Tuff Complex. Various called Ileret, Lower/Middle and Koobi Fora Tuff Complexes, these are thought to be stratigraphical correlatives of the Okote Tuff Complex^{2,3,5,11}. Cerling and Brown showed³, however, that glass separates from pumice and from tuff display considerable compositional variability, such that definite correlations between individual tuffs in the different areas was not possible. As the compositional variations observed lie on well defined trends, they suggested³ that the tuffs are all genetically related, and, therefore, probably correlatives on a broad time-scale. Studies by Brown and Feibel⁵ have subsequently yielded some correlations. The age derived here for pumices in one of the tuffs in the Okote Tuffs Complex can thus be regarded as providing an approximate guide to the age of the other tuff sequences referred to above.

The well-constrained maximum age for a tuff within the Okote Tuff Complex provides excellent time control for the abundant vertebrate faunas, including hominids, that occur in the upper part of the Koobi Fora Formation. Correlations indicate that the recent important *Homo erectus* find at Nariokotome on the west side of Lake Turkana also was from a stratigraphical level equivalent to that of the Okote Tuff Complex^{4,5}. Together with the dating results reported by McDougall¹² on feldspars from pumice clasts in other tuffs in the sequence, a detailed chronology for the Koobi Fora region is emerging. The successful geochemical correlation of tuffs between the sequences at Koobi Fora, the Lower Omo Valley just north of Lake Turkana (Shungura Formation) and the west side of Lake Turkana, strongly supports the idea that the sediments belong to a single major depositional system within the Turkana Basin^{3,5,17}. The chronology also can be applied throughout the region, with measurements on samples from different parts of the Turkana Basin contributing to the overall picture. The available data

suggest that accumulation of sediments in the Turkana Basin began ~4.1 Myr ago in the early Pliocene, and has continued until the present day, although quite lengthy hiatuses, representing periods up to or exceeding 0.5 Myr, are recognized in individual sequences^{12,17}.

The National Museums of Kenya and the Government of Kenya facilitated the field work. We thank R. E. F. Leakey for encouragement and for field support, and F. H. Brown for stratigraphical information.

Stratigraphical notes on the Okote Tuff Complex at Koobi Fora, Kenya

F. H. Brown & C. S. Feibel

Department of Geology and Geophysics, University of Utah, Salt Lake City, Utah 84112, USA

The Okote Tuff Complex of the Koobi Fora Formation in northern Kenya contains many archaeological sites¹ and many hominid specimens derive from levels nearby². The complex lies between the KBS Tuff and the Chari Tuff, both of which have been precisely dated^{3,4}, and recently McDougall (in the accompanying manuscript)⁵ has measured the age of pumice clasts derived from the complex. The pumices, however, differ in composition from the tuff in which they were deposited. The age is still useful, because a tuff of known stratigraphical position in the Shungura Formation is of the same composition. Here we discuss stratigraphical relations between the Okote Tuff Complex and other related strata at Koobi Fora, in the lower Omo Valley, and west of Lake Turkana based on compositional study of ash layers. This allows us to estimate an age of 1.60 ± 0.05 Myr for the *Homo erectus* skeleton recovered at Nariokotome in 1984 (see accompanying article⁶).

Several conditions have contributed to the difficulty of framing a general stratigraphy in this part of the section, or even to defining the sequence of tuffs which occur. The first is that in many localities only a single tuff or a pair of tuffs is exposed, and it is often difficult to determine the order of tuffs where exposures are poor because many of them occur discontinuously as channel fillings. Many of the tuffs in this interval have reasonably similar composition with respect to both major and trace elements; each of them is variable in composition so that where few analyses are available, samples which actually belong to a single group may be placed into different categories. Some of the tuffs are composed of shards of more than one composition⁷, and fractionation may have occurred either naturally (by differential weathering) or in the laboratory (by bias towards more or less magnetic fractions during electromagnetic separation). Finally,

Fig. 1 a, Location map; b, Correlated stratigraphical sections through the Okote Tuff Complex in the lower Omo Valley and the Koobi Foraregion.

the sequence is obscured if analyses of pumice and fine-grained ash are considered together; only after separation of the pumice analysis from those of the tuffs does the situation become clearer. These problems can be overcome provided there are enough analyses to determine the variation in composition of a particular tuff, and provided the analyses are done on samples from more than one section so that sequences can be shown to be homotaxial. Stratigraphical statements made here are based on 143 individual analyses of glass from tuffs and from pumices contained within them which lie between the KBS and Chari Tuffs.

There are two key sections on which the present stratigraphical conclusions are based, one situated in area 131 on the Karari Ridge, the other situated in the lower Omo Valley (Fig. 1a, b). In a detailed section in area 131, there are 14 tuffs or tuffaceous layers beginning with the KBS Tuff and ending with the Chari Tuff. We view three layers near the middle of the section as products of a single eruption because they are compositionally identical. The section of the Shungura Formation is composite, but tuffs discussed here were collected from a single section at Ilgwa (see ref. 8); analyses are given in Table 1. A third section located near Koobi Fora spit is necessary to place the Koobi Fora Tuff (defined below) in this sequence.

On the basis of the stratigraphical order of tuffs in these sections, and the composition of the ash fractions, the correlations shown in Fig. 1b have been made. Appended names are explained below. We realize that this stratigraphy is incomplete—indeed we have analysed 10 other tuffs known to lie within this same interval, but which are less well constrained stratigraphically, and thus not reported here.

In previous reports concerned with the stratigraphy of this interval¹⁹⁻²⁰, the tuffaceous part of the section along the Karari Ridge was referred to as the Okote Tuff Complex (or as the Okote Tuff); at Ileret, the Lower/Middle Tuff Complex (or Middle Ileret Tuff); and near Koobi Fora spit, the Koobi Fora Tuff Complex. With the exception of the Okote Tuff Complex defined by Findlater¹³, these terms are informal. To clarify stratigraphical relations between the three areas at Koobi Fora we here name several tuffs which have formerly been treated as parts of one or another of the complexes. For each newly named tuff we designate a type locality and give a short description; representative analyses of each are given in Table 1.

A tuff in area 104 has been informally known as the White Tuff; it is also present in area 131 where it is the lowest recognized ash layer mapped as the Okote Tuff Complex. We define this tuff as the White Tuff, and designate its type locality as (1750/043, 103) (ref. 21) in area 131 of the Koobi Fora region where the tuff is reasonably well exposed, and where its relation to other tuffs in the Okote Tuff Complex can be seen. This tuff is ~40-cm thick, fine grained, and very pale grey to white. It is composed dominantly of colourless shards with tubular vesicles. Its very pale colour is diagnostic in the field and its composition is unique.

About 2 m higher in the section in area 131 there is a medium-grey tuff ~80-cm thick (K83-1629, Table 1) which we do not name. Filling a channel in the upper part of this tuff is another ash ~40-cm thick which we designate the type locality of the Kimire Tuff, named for the stream in which it is exposed. Photo coordinates of this locality are 1750/054, 131. (Photo coordinates refer to aerial photography HSL KEN 70 6 flown by Hunting Surveys Ltd. The notation is read as photo number/x, -y with the x distance in millimetres from the left hand margin of the image and the y distance in millimetres from the top of the image. A set of these photos exists in the Koobi Fora archives at the National Museums of Kenya in Nairobi.) Shards with spherical bubbles make up about half of the Kimire Tuff; the remainder are striated, bubble junction or bubble wall shards. This tuff cannot be distinguished chemically from the Lower Koobi Fora Tuff; it is separated here because the stratigraphical relations are clear. Isolated samples from other localities could be referred to either the Kimire Tuff or to the Lower Koobi Fora Tuff.

A thin sandstone lies between the Kimire Tuff and the next tuff which we designate the Lower Okote Tuff (Type locality 1750/057, 133). The pumices dated by McDougall⁵ derive from this horizon, but are chemically very distinct from the enclosing ash. The Lower Okote Tuff (1.6 m) is medium grey, fine to medium grained, and composed dominantly of shards with elongate vesicles with a smaller fraction of bubble junction shards. Although similar in composition to some other ashes in this same stratigraphical interval, the Lower Okote Tuff is reasonably well defined compositionally.

There are four pumiceous tuff beds 2 m above the Lower Okote Tuff, which comprise ~6 m of the section. The lower

three of these are compositionally identical (Table 1), and as these comprise the greatest thickness of ash at this locality we designate these three beds the Okote Tuff. At the type locality (1750/061, 137) the Okote Tuff (4 m) is medium grey and consists of a mixture of shard types. Compositionally this tuff is well defined, and corresponds to a 1.4-m ash layer which lies ~1 m below the Lower Koobi Fora Tuff in area 101.

The fourth Tuff in the sequence described above correlates with the base of the thick tuff in area 101 which has been informally regarded as the type locality of the Koobi Fora Tuff⁸. Here we designate the tuffaceous section in area 101 as the type locality of both the Lower Koobi Fora Tuff and the Koobi Fora Tuff (1343/102, 173). There is no clear stratigraphical break between the lower and the upper part of the thick tuff in area 101, but the base is compositionally distinct from the upper part (see Table 1). In other parts of the Koobi Fora region, ashes of each composition are found as discrete layers. The lowest 4.1 m of section at the type locality is taken as the type of the Lower Koobi Fora Tuff; the upper 3.3 m of section at the same locality is taken as the type of the Koobi Fora Tuff. Both of these tuffs are composed dominantly of shards with tubular vesicles with a few blocky or bubble junction shards. The Koobi Fora Tuff

probably correlates with Tuff J-6 of the Shungura Formation, although there are minor differences in composition (Table 1). In area 131, the Koobi Fora Tuff has not been identified, probably because the Lower Koobi Fora Tuff is terminated there by an erosional surface with at least 3-m relief.

Encased within the sandy section overlying the Lower Koobi Fora Tuff in area 131 is a distinctive tuff composed of both grey and brown shards. There it occurs in a channel lined with ash, filled with black pumice clasts up to 25 cm in diameter, but also contains grey pumice clasts of similar size. We here designate this tuff as the Black Pumice Tuff. It is 0-1 m thick at its type locality (1750/060-139), pale brownish yellow in hand specimen, and composed dominantly of flat bubble junction shards. Compositionally this tuff, though variable, is unmistakable (Table 1); it correlates with Tuff J-7 of the Shungura Formation. (Two other separates have been analysed from the section in area 131 between the Black Pumice Tuff and Chari Tuff (K83-1645; K83-1647; Table 1, Fig. 2), but as they are known only from this locality, we do not name them here.)

Turning to the composition of the pumice clasts, we find that most can be accommodated in the analytical groups defined using ash samples only. One fact becomes immediately clear

from the analyses of pumice clasts—pumices are not confined to the tuff which they match compositionally, but may be found also in tuffs and other sediments at higher stratigraphical levels. For example, the Koobi Fora Tuff contains not only pumice corresponding to its own composition, but also pumices which compositionally match the Lower Koobi Fora Tuff and the Okote Tuff. This causes the problem of interpreting the ages on the pumices from the Lower Okote Tuff, because they do not correspond to the composition of that tuff. Clearly, the measured ages refer to the time of eruption of the pumice, and must antedate the time of deposition of tuff in which they are included. In a general sense, the effect of upward reworking of pumice clasts in a section is to make the entire section appear older than it actually is. In contrast to pumices, which maintain their integrity even during and after reworking, ash layers are not often redeposited as discrete layers. (There are, however, examples of redeposited ash layers in the region.) Hence, we argue that the age on pumice clasts must be applied stratigraphically to the first appearance of an ash in the section which corresponds to the composition of the dated pumice.

The pumices from the Lower Okote Tuff correspond in composition to Tuff J-4 in the Shungura Formation of southern Ethiopia, and also to a tuff exposed west of Lake Turkana, but do not correspond to that of any tuff yet analysed from the Koobi Fora region. We believe that the age reported by McDougall¹ may be applied to Tuff J-4 of the Shungura Formation. Using this age, we can estimate ages of tuffs lying between J-4 and Tuff L in the Shungura Formation by scaling on the basis of stratigraphical thickness. This in turn allows us to set limits on the age of the Lower Okote Tuff, knowing that it is 1.64 ± 0.03 Myr. Using various sections for scaling, the Black Pumice Tuff (Tuff J-7) is found to have an age between 1.52 and 1.57 Myr, hence the Lower Okote Tuff must lie between 1.64 and 1.52 Myr. If a further correlation is accepted (that between Tuff J-6 and the Koobi Fora Tuff), then the age of the Lower Okote Tuff is further constrained to lie between 1.60 and 1.64 Myr, which is virtually the same as the error in the reported age. In this case, the tuff in question is only slightly younger than the pumices included within it even though they differ in composition. The lowest tuff known to have been mapped within the Okote Complex is the White Tuff which can be assigned an age of ~ 1.7 Myr by stratigraphical scaling of the section in area 131.

Detailed correlations between the Karari Ridge and the Ileret area are still not completely clear. The Lower Koobi Fora Tuff and the Koobi Fora Tuff have been identified in areas 6, 6A and 8A in the southern part of the Ileret Area, and these lie above the Lower Ileret Tuff²⁰. We can set no useful lower boundary on the level of the Lower Ileret Tuff, although it is known to overlie the KBS Tuff. The Black Pumice Tuff has also been identified in area 8A. The prominent tuff exposed below the Chari Tuff along the northern part of the Ileret Ridge does not correlate with any of the tuffs reported here, nor with any other known tuff from the region.

In conclusion, the Okote Tuff Complex and the Koobi Fora Tuff Complex as a whole probably lie within the interval between 1.5 and 1.7 Myr. The stratigraphical interval between the KBS Tuff and the Okote Tuff Complex represents a period of no more than 200,000 yr. Several archaeological sites can now be placed into an ordered sequence along the Karari Ridge, and with further work others will undoubtedly be placed as well. The tuff which lies 50 cm below the *Homo erectus* skeleton announced in the accompanying article⁶ (KNM-WT-15000), on the west side of Lake Turkana correlates either with the Kimire Tuff or with the Lower Koobi Fora Tuff; until other tuffs lying lower in the section at the site are analysed it is not possible to decide which. But it is clear that the hominid specimen must lie between 1.55 and 1.65 Myr in age.

Financial support for this work was provided by NSF grants BNS-8210735, BNS-8406737 and by a grant from the National Geographic Society. Logistic support was provided by the National Museums of Kenya.

A new form of energy dissipation by a moving object in He II

G. G. Nancolas*, T. Ellis*, P. V. E. McClintock* & R. M. Bowley†

* Department of Physics, University of Lancaster, Lancaster LA1 4YB, UK

† Department of Physics, University of Nottingham, Nottingham NG7 2RD, UK

Despite the superfluid^{1,2} character of ⁴He below the λ transition temperature, there are two distinct mechanisms by which an object moving through the liquid dissipates kinetic energy: (1) it can scatter^{3–5} the excitations (rotons, phonons, ³He isotopic impurities) that constitute the normal fluid component; and (2) for speeds in excess of the Landau critical velocity⁶ (v_L), it can create rotons⁷, apparently in pairs^{7,8}. The first process has been studied extensively, mostly by measurements of the zero-field mobilities of positive and negative ions^{3–5,9–11}. The second process, which is much rarer, has also been investigated in considerable detail^{12–14} by studies of the motion of negative ions in isotopically pure ⁴He at elevated pressures. Here, we report an attempt to extend the latter type of investigation to lower pressures. This yields unexpected results that can be accounted for satisfactorily only if we postulate the existence of a third dissipation mechanism.

All the experiments were carried out at temperatures low enough that the influence of process (1) could be ignored. At high pressures, P , the drift velocity, $\bar{v}$, of a moving ion is limited by roton pair creation. In weak electric fields, it is accurately described^{12,13} by

$$\bar{v} = v_L + AE^{1/3} \quad (1)$$

where the constant A can be expressed¹⁵ as

$$A = \left(\frac{5.36 e \pi^2 \hbar^3 v_L^2}{m_i k_{0i}^4 V_{k_0, k_0}^2 \mu_r} \right)^{1/3} \quad (2)$$

m_i is the ionic effective mass, k_0 and μ_r are the roton wave vector and effective mass and V_{k_0, k_0} is the matrix element, unknown *a priori*, that characterizes the pair-emission process. The experimental technique developed for the determination of $\bar{v}$ in weak electric fields has already been outlined^{16,17} and will be described in detail elsewhere¹⁸. Briefly, a group of ions is field-emitted into a large volume (~ 1.5 l) of isotopically purified liquid ⁴He at ~ 80 mK and their average velocity in traversing

Fig. 1 The modulus of the matrix element $|V_{k_0, k_0}|$, for roton pair creation by negative ions in He II plotted as a function of pressure, P . The solid line has been fitted to the data by the method of least squares.

a region of weak uniform electric field is then measured by means of a time-of-flight technique. Comparison of the experimental $\bar{v}(E)$ data with equations (1) and (2) enables v_L and $|V_{k_0, k_0}|$ to be determined. The values of v_L are found¹⁶⁻¹⁸ to agree to within 1.5% with those calculated from the Landau theory⁶ on the basis of accepted values¹⁹ of the roton parameters. The experimental $|V_{k_0, k_0}|$, incorporating measured²⁰ values of m_+ , are plotted as a function of pressure in Fig. 1. It can be seen that $|V_{k_0, k_0}|$ decreases rapidly with falling P and that a linear extrapolation would imply that it became zero at ~ 3 bar. (Metamorphosis of the bare ions to charged vortex rings^{21,22} prevents the extension of this type of experiment much below 13 bar.)

Although there is no theoretical justification for a linear extrapolation *per se*, it seems reasonable to conclude from Fig. 1 that the probability of roton pair creation will become very small at low pressures. One possibility is that V_{k_0, k_0} may pass through zero and change sign at some characteristic pressure. Without an explicit physical model of the roton creation process, one can only guess at the underlying reasons for such behaviour. It seems probable that the most significant result of reducing P is the consequent expansion^{5,20} of the ion; it is conceivable that there may be some critical ionic radius at which the two rotors of a nascent pair will tend to interfere destructively, effectively reducing the probability of the emission event in question.

Regardless of the correctness of such speculations, it is of considerable interest to investigate the behaviour of bare ions moving through He II at low pressures: for low enough temperatures, in isotopically pure ^4He , process (1) can be disregarded; and the data of Fig. 1 strongly imply that process (2) will also be ineffective as a significant source of drag. What, then, will limit the speed of an ion moving under the constant force arising from an external electric field?

An experiment to investigate this question seems at first sight to be precluded by the rapidity with which bare ions undergo the transition to charged vortex rings at low pressures, thereby being lost from the propagating ion cloud whose drift velocity is to be measured. The transition can, however, be suppressed²³ by the application of electric fields $> 2 \text{ MV m}^{-1}$. Measurements in these conditions are not straightforward because of the need to maintain electric fields above this value throughout the whole transit of the ion from source to collector; but they are possible. We have performed a set of measurements of $\bar{v}(P)$ for $E = 2.6 \text{ MV m}^{-1}$ extending down to 1 bar (Fig. 2).

Although the data are subject to considerable scatter, it is immediately evident that the form of $\bar{v}(P)$ is very different from what might reasonably have been anticipated (Fig. 2). As P is reduced below 25 bar, $\bar{v}$ at first increases. This was as expected: first, because of the increase of v_L (dashed line) which causes $\bar{v}$ also to increase (so that, if $\bar{v} - v_L$ were to remain constant, the data would follow the dash-dotted curve); and, second,

Fig. 2 The drift velocity $\bar{v}$ of negative ions in He II at 0.3 K under an electric field of 2.6 MV m^{-1} , plotted as a function of pressure, P . The dashed curve shows the pressure dependence of the Landau critical velocity for roton creation; the dash-dotted curve indicates the form of $\bar{v}(P)$ that would be expected if $(\bar{v} - v_L)$ remained constant as P was reduced from 25 bar. Squares represent data acquired through use of the electric induction technique described previously²² and circles represent measurements made with a modified (single grid) form of the same technique that has been devised to enable the electric field criterion in the text to be satisfied, and which will be described in detail elsewhere.

because of the decrease of $|V_{k_0, k_0}|$ which causes $\bar{v}$ to rise above the dash-dotted line as is indeed observed. This trend is not, however, continued to lower pressures. Rather, $\bar{v}(P)$ passes through a maximum at ~ 16 bar and then falls rapidly to reach a value near 1 bar that is actually below v_L . The latter observation clearly demonstrates that the drag force that limits $\bar{v}$ at the lower pressures cannot possibly arise from any form of roton emission. Therefore, it seems necessary to conclude that there exists some new dissipation mechanism as well as (1) and (2) mentioned above.

The average rate of energy dissipation by the ion may be written as

$$eE\bar{v} = 2\Delta R_2(\bar{v}) + \dot{\epsilon}_v \quad (3)$$

where the first and second terms on the right correspond, respectively, to dissipation through roton emission and through the unknown additional mechanism, Δ is the roton energy gap and $R_2(\bar{v})$ is the roton pair creation rate. Knowing $\bar{v}$, v_L and the matrix element for pair production (Fig. 1) we can calculate^{7,15} the rate of energy loss through roton creation; by subtraction of this quantity from our measured values of $eE\bar{v}$ we then obtain $\dot{\epsilon}_v$. Application of this procedure to the $\bar{v}(P)$ data of Fig. 2 yields the $\dot{\epsilon}_v$ values shown in Fig. 3. The error bars show the effect of a $\pm 5\%$ uncertainty in the matrix element and the random error in the data is indicated by their scatter. It is evident that the additional dissipation mechanism at first intensifies

Fig. 3 The rate of energy loss, $\dot{\epsilon}_v$, caused by the new dissipation mechanism for a negative ion moving in an electric field of 2.6 MV m^{-1} . The points, calculated as described in the text from the data in Fig. 2, are plotted as a function of pressure, P . Bars indicate the effect of a $\pm 5\%$ change in the value used for $|V_{k_0, k_0}|$.

slightly with increasing pressure, passes through a maximum at ~ 8 bar and then falls quite steeply, approaching zero near 25 bar.

We propose that a probable candidate for this unknown source of drag lies in the continuous production of microscopic quantized vortex rings. That is, rather than undergoing the well-known transition to a charged quantized vortex ring, the ion creates a succession of elemental rings to which it does not bind. Such a phenomenon is anticipated²⁴ on the basis of Schwarz and Jang's symmetrical creation model^{25,26} of the transition; it could conceivably also occur for the alternative vortex loop model²⁷ if the elemental loop were to become unstable in very high electric fields. We infer that the process can happen at all pressures but that it does so much more weakly at the higher values of P , mainly because of the opposing pressure dependences of v_L and the critical velocity v_c for vortex nucleation. The existence of such a phenomenon would also provide a plausible explanation for the observed small departures¹⁴ of $\bar{v}(E)$ from the behaviour predicted by the roton pair emission theory for large E at 25 bar.

Two specific points arise concerning the relationship of our present results to the large body of work on the interaction of ions with vortices in He II. First, it is well established that, for non-zero temperatures, there is a finite probability of an ion escaping from the vortex on which it is trapped, as the result of a thermal fluctuation²⁸⁻³⁰. In some conditions, therefore, the ion can proceed through the liquid in a series of distinct epochs such that it exists for part of the time as a bare ion and for the rest of the time forms part of a charged vortex ring³¹⁻³⁶. Initially, the ion accelerates under the influence of the applied electric field, and provided that its velocity $v \geq v_c$, the transition to a charged vortex ring may occur. The ring grows and slows and, eventually, particularly for strong electric fields, the ion may escape from the ring through a thermal fluctuation^{31,35,36}; it then starts to accelerate again, and so on. (In those cases where the electric field is inadequate to maintain the stability of the ring against process (1), but still sufficient to cause $v \geq v_c$, the ring shrinks, accelerates and disappears, again liberating the trapped ion^{32,34}; the process then repeats, as before.) The mechanism envisaged here is distinctly different in character, however, in that charged vortex rings as such are not created because trapping of the ion on the nascent ring does not occur: the 'moving object' therefore maintains its continuity of existence as a bare ion. Second, the notion that a moving ion might be able to create a sequence of uncharged microscopic vortex rings was proposed several years ago by Huang and Olinto³⁷. Their suggestion related to a theoretical explanation for the Careri mobility steps which, unfortunately for the theory, were subsequently shown to have been, if not an artefact, then some classical phenomenon quite unconnected with the quantized vorticity of the superfluid under consideration. But, although incorrect in its original context, their proposal can provide a basis for the interpretation of the present experiments.

We may interpret Fig. 3 in the following way. The rate of energy loss to vortex rings can be written

$$\dot{E}_v = \nu E_{\text{ring}} \quad (4)$$

where ν is their nucleation rate and E_{ring} is their average energy. The dissipation rate through this process becomes very small at large P because, for any given velocity, rotons are then more strongly emitted: this is partly a result of the decrease of v_L , partly because of the increase in $|V_{k_0, k_0}|$ and partly as a result of the increase of v_c . The dissipation rate also exhibits a slight decrease at low P , mainly because the ion is travelling more slowly, which is attributable to the decrease of v_c with falling P . The data in this range seem to favour the Muirhead *et al.* theory²⁷ of vortex nucleation slightly over that of Bowley²⁶, for which the predicted pressure dependence of v_c is weaker.

The situation is, however, complicated, first, because of the changes to be anticipated in E_{ring} owing to the pressure dependence of the ionic radius and, second, because of our ignorance of the distribution function of ionic velocities in these conditions. The vortex nucleation rate itself cannot, of course, be evaluated without a knowledge of E_{ring} ; but, if we make the plausible

assumption that the radius of the ring will be ~ 2 nm, slightly larger than the radius of the ion, so that $E_{\text{ring}} \approx 5 \times 10^{-21}$ J, we find from equation (4) that $\nu \approx 4 \times 10^8 \text{ s}^{-1}$ at zero pressure. The latter value seems physically reasonable.

In conclusion, it seems that a third form of drag exists on a moving object in He II, and we suggest that it corresponds to the production of a stream of quantized vortex rings.

Image distortion near galaxies: dwarfs or lensing?

J. Anthony Tyson

Physical Research Laboratory, AT+T Bell Laboratories, Murray Hill, New Jersey 07974, USA

Gravitational lensing is a useful tool for studying the mass distribution in galaxies. The average gravitational lens distortion of background galaxy images by foreground galaxies is an independent non-kinematical measurement of galaxy mass distribution M/r (ref. 1), where M is the mass of the galaxy and r its radius. Using an indirect calculation involving estimated luminosity functions and absolute magnitudes, Philipps² recently claimed that our measurement of field galaxy mass distribution by galaxy-galaxy gravitational lensing was contaminated by large numbers of foreground dwarf galaxies. I present here a direct measurement of this effect: the cross-correlation between these samples clearly reveals clustering of foreground dwarf galaxies, with an amplitude slightly less than that given by our original simulation¹. Thus, this effect does not change our conclusions regarding the average galaxy mass distribution.

Galaxy mass can be expressed as an equivalent orbit velocity at some radius. The upper limit we obtained for the equivalent

Fig. 1 Dwarf galaxies clustering about bright galaxies. The two-point cross-correlation function is plotted for the foreground galaxies and background galaxies used in the determination of galaxy mass distribution by gravitational light deflection¹. Note that contamination of the background galaxy data set by sub-luminous clustered foreground galaxies is small ($\sim 10\%$) at 10 arc s angular separation between the bright and faint galaxies. Even-odd bin round-off effects at small separation angle have not been corrected. The amplitude of this correlation function is 12 times less than that predicted by Phillipps², and is in reasonable agreement with our simulation.

circular velocity, while small compared with some heavy halo models, is consistent with dynamically derived estimates for a sample of galaxies of all types¹. For example, for a mean mass cut-off radius of $65 h^{-1} \text{ kpc}$, our 3σ upper limit for the equivalent circular velocity $\langle v_c \rangle = [(GM)/r]^{1/2} = 190 \text{ km s}^{-1}$, [h is the value of the Hubble parameter in units of $100 \text{ km s}^{-1} \text{ Mpc}^{-1}$]. The search for a statistical gravitational-lens image distortion of background galaxy images about the positions of foreground galaxies is complicated by several low-level systematics. We obtained upper limits to many systematics by substituting either random positions or stars for the foreground or background galaxies. Remaining contaminating effects, which are largest at small angular separations, must be modelled, simulated or, even better, measured directly.

Our foreground sample of galaxies has magnitudes in the range 19–21.5 J mag. Our background sample covers 22.5–23.5 J mag. A fraction (originally estimated¹ at 15%) of our 'background' galaxies are actually sub-luminous galaxies physically clustered with our foreground galaxies. This effect is one of several known systematics of which we were aware and which are corrected¹. However, a direct measurement is always better than a calculation.

The average magnitude of galaxies in our foreground sample is 20.75 J mag and that of our background sample is 23.06 J mag. Thus, any physical companions of the foreground galaxies, appearing as background galaxies, have absolute magnitudes about 2 J mag fainter than the average foreground galaxy in our sample.

I can test the hypothesis of significant dwarf galaxy contamination of our background sample by direct internal analysis of our data, without reference to any assumed luminosity function. Phillipps claims that large numbers of dwarf galaxies clustering about our foreground galaxies dilute our true background sample by a factor of 4–1.5 over the range 4–40 arc s separation angle, giving a cross-correlation function³ $w_x(\theta) = 9\theta^{-0.8}$, where

$w_x(\theta)$ is the excess probability, over random, of finding a faint galaxy near a bright galaxy, separated by an angle θ . This prediction by Phillipps is a necessary condition for his conclusion; that is, if $w_x(\theta)$ for our observations falls significantly below $9\theta^{-0.8}$, for whatever reason, this hypothesis fails.

Taking the same foreground and background galaxy data sets used in our galaxy mass determination¹, and forming the two-point cross-correlation function, I obtain the correlation shown in Fig. 1. There were 1.3×10^7 galaxy pairs in the cross-correlation, with average magnitudes of 21.04 and 23.06 J mag in the foreground and background samples, respectively. The best-fit line has the same slope (-0.77) found in our galaxy autocorrelation functions. I obtain (3σ):

$$w_x(\theta) = (0.7 \pm 0.1)\theta^{-0.77} \quad (1)$$

This is a factor of 12 below Phillipps' estimate, and is close to our original¹ estimate, based on a Monte-Carlo simulation using a Schechter luminosity function. In the range of θ that dominates our gravitational lens distortion measurement ($0.7 < \log \theta < 1.5$), our measured $w_x(\theta)$ averages $< 10\%$. Our original plots of image distortion were corrected for 15%. Thus, our equivalent circular velocities were overcorrected by 5%, and the effect of our new calibration of this effect is slightly to enhance our null result, the conclusions of our paper being unchanged. The formal discrepancy between Phillipps' estimate and our observations is 38 s.d. Thus, intrinsically faint galaxies do not significantly contaminate our background sample. Below I briefly discuss the apparent origin of Phillipps' anomalously large amplitude.

To estimate this contamination effect indirectly, we require the luminosity function in some standard system, and then we must transfer J magnitudes of average and dwarf galaxies onto that system. Using $B = J + 0.23(B - V)$, $B - V = 0.8(J - F)$ and the mean $B - V$ colours of average and dwarf galaxies at 21 J mag (1, 0.3), I obtain $B_{fg} = 21.2$ mag and $B_{fg} = 23.0$ mag for the mean apparent B magnitudes of these two galaxy type samples in our foreground sample. The colour-dependent K -corrections at $J = 21$ mag ($z = 0.2$) will be different for the dwarf and average galaxy samples. I estimate the difference in the colour terms as $\Delta K = 0.8$ mag. Since $B - M_B = 25 - 5 \log h + 5 \log r + K$, I obtain $M_{Bd} - M_B = 2.4$ mag for the difference between the dwarf and average galaxy absolute magnitudes in our foreground sample. If $\langle M_B \rangle = -20$, then $\langle M_{Bd} \rangle = -17.6$ mag.

Historically, published values for the galaxy luminosity function, without regard for the depth of the sample, have varied widely. Phillipps chose the value $0.05 h^3 \text{ Mpc}^{-3} \text{ mag}^{-1}$ from a range of observed values⁴. Recent deeper and more statistically homogeneous galaxy samples^{5–7} have given differential luminosity functions at $M_B = -17.6$ mag ranging from 0.006 to $0.015 h^3 \text{ Mpc}^{-3} \text{ mag}^{-1}$. Using $0.01 h^3 \text{ Mpc}^{-3} \text{ mag}^{-1}$, Phillipps' result would be within a factor of two of our measurement, well within the errors of his estimate. Felten⁸ argues for even lower values for higher redshift samples of field galaxies. Another theoretical estimate for this effect, which would predict negligible contamination for our sample, can be found in ref. 9, Table 4.

In this instance, due to uncertainties in published galaxy luminosity functions, a direct measurement of the two-point cross-correlation function of our foreground and background galaxy samples is more reliable than any calculation based on assumed luminosity functions and K -corrections. Given some foreground galaxy redshifts, cross-correlations in these faint galaxy samples may eventually yield new data on the faint end of the galaxy luminosity function.

Intermittent baroclinic instability and fluctuations in geophysical circulations

R. W. Griffiths* & P. F. Linden†

* Research School of Earth Sciences, Australian National University, PO Box 4, Canberra 2601, Australia

† Department of Applied Mathematics and Theoretical Physics, University of Cambridge, Silver Street, Cambridge CB3 9EW, UK

The presence of blocking highs in atmospheric circulation, bringing periods of stable weather alternating with more variable weather patterns, is an example of two distinct modes of behaviour occurring under similar conditions in a natural system. The occurrence of two or more different flow regimes under a given external forcing is a consequence of nonlinear dynamics that allows the system to equilibrate in different modes. Each mode can be stable over a range of conditions and yet there may be sudden transitions between modes. We have now discovered in a laboratory experiment using rotating fluids a case of at least two modes of behaviour under identical conditions. In one mode, a weak continuous forcing drives a mean circulation that is steady but on which are superimposed waves whose amplitudes vacillate under the influence of viscous dissipation. Under suitable conditions there is an alternative mode in which the mean flow fluctuates and unstable waves occur only in short bursts at periodic intervals separated by relatively long periods of stable flow with no waves. The existence of multiple equilibrium states is of interest in the climatology of all geophysical and astrophysical fluid bodies. Our discovery of a mode involving intermittent bursts of instability and long-period fluctuations of mean flow (resulting purely from internal dynamics rather than from variations in external forcing) may have implications for the variability of oceanic circulation or solar radiation on timescales of a few years to centuries.

The condition of solid-body rotation (or zero motion relative to a rotating reference frame) can never be attained by a fluid containing gradients of temperature or chemical composition¹. This is because diffusion of density across the curved surfaces of constant density drives a meridional (Eddington-Sweet) circulation in planes parallel to the axis of rotation^{2,3}. Conservation of angular momentum of the circulating fluid in turn leads to an even larger azimuthal flow with an associated vertical shear and finite inclination of surfaces of constant density relative to surfaces of constant pressure. This azimuthal flow can, under suitable conditions, be unstable to perturbations that convert gravitational potential energy into kinetic energy of waves or of irregular eddy motions superimposed on the mean circulation⁴; this mechanism for conversion of energy is termed baroclinic instability.

In our experiments, a cylindrical container of radius $R = 30$ cm and with a planar base perpendicular to gravity, rotates

with angular velocity Ω about an axis through its centre and parallel to gravity. A layer of water 10 cm deep is allowed to approach solid-body rotation before a dilute sugar solution ($0.5\text{--}5 \times 10^{-3} \text{ g g}^{-1}$) is slowly released onto the base from a small tube against the wall. Once a lower layer has accumulated to a depth of 10 cm, the pipe is removed and the top of the container sealed to prevent surface stress and evaporative cooling. Vertical motions of the density interface are detected by conductivity probes on the axis of rotation and at a radius of 20 cm. Each probe consists of a platinum wire electrode suspended vertically through the interface⁵. A small amount of salt is mixed with the upper layer before filling to produce a conductivity contrast between layers and the circuits are completed through a flat plate electrode on the wall of the container.

The vertical position z of the density interface on the axis of rotation is a convenient measure of the azimuthal circulation. In fact, by considering conservation of momentum and volume in each layer, it can be shown that variations of z at the centre of the cylinder are caused primarily by variations of a horizontally averaged velocity difference between layers (the radial pressure gradient resulting from the sloping interface being everywhere in approximate balance with Coriolis forces). Waves are not detected at the axis when the flow is unstable because they have a node at the centre and a maximum amplitude somewhere near the wall. On the other hand, conservation of volume implies that mean circulations have little influence on interface height 20 cm from the axis, where the second probe is located, so that the latter detects only waves and eddies.

After filling and a period during which relative motions induced by the filling procedure decay, diffusion of sugar across the thin interface begins to have a significant effect. Baroclinic instability of the resulting azimuthal flow depends on the internal Froude number $F = 4\Omega^2 R^2 / g(\Delta\rho/\rho)h$ (h is the depth of both layers, g the gravitational acceleration and $\Delta\rho/\rho$ the fractional density difference), the influence of friction expressed in terms of the Ekman number $E = \nu/2\Omega h^2$ (ν is the kinematic viscosity) and the Rossby number $Ro = \Delta U/2\Omega R$ (ΔU is a characteristic velocity difference^{4,5}). Waves are predicted to grow when $F > 0(10)$ and $E^3 Ro^{-1} < 0(1)$. In the present system, the velocity difference ΔU is a function of solute diffusivity, interface thickness and curvature of density surfaces (or $\Omega^2 R/g$). The above criterion, using a velocity scale measured from floating markers, predicts instability for all experiments in which the outer probe detected the growth of waves. As predicted, no waves appeared in experiments for which $F < 10$. Although the Eddington-Sweet circulation driven by solute diffusion has been detected previously in laboratory experiments⁶, its instability has not.

Other phenomena detected in our experiments are wave amplitude vacillation and the influence of instability on the mean flow. In Fig. 1 the waves persist with a mean amplitude that remains nearly constant over long times, apart from obvious amplitude vacillations that are a common feature of finite amplitude baroclinic waves^{5,7-10}. At the same time the mean azimuthal circulation is practically invariant, implying a balance between spatially averaged dissipation and forcing over all timescales.

Fig. 1 Vertical displacements of the density interface as functions of time after filling as detected by conductivity probes at the axis of rotation (heavy line) and at a radius of 20 cm (lower trace) for an experiment in which $\Omega^2 R/g = 4 \times 10^{-2}$, $E = 8 \times 10^{-3}$, $Ro = 0.03$ and $F = 76$; $\Omega = 1.2 \text{ rad s}^{-1}$, giving a rotation period of 5.2 s. Baroclinic waves are continuously present and the mean flow is essentially steady.

Fig. 2 Vertical displacements of the density interface in an experiment similar to that of Fig. 1 but with $F \approx 150$. Rotation period, 5.2 s. Baroclinic waves are continuously present (light trace) but induce fluctuations in the mean flow (heavy line).

Fig. 3 Displacements of the density interface during two separate periods for the experiment of Fig. 1, showing the effect of an 8% increase in Ω at 21.6 h after filling. Baroclinic waves appear only intermittently (light trace) and the mean circulation (heavy line) eventually settles into a period oscillation. In this experiment, the periodic oscillations persist for 80 h until diffusion has so altered the density distribution that waves dies out.

When the experiment is repeated with the density difference halved, waves are again continuously present (Fig. 2). However, they show larger fluctuations of amplitude, and there are marked fluctuations in the mean azimuthal flow. In this case it seems that the forcing and dissipation are not in balance even over timescales up to hundreds of rotation periods.

The interaction of unstable waves with the mean flow can give rise to two flow regimes in a given experiment. A transition can be achieved by inducing a small instantaneous increase in

the angular velocity of the container. Figure 3 shows the result of increasing Ω from 1.2 rad s^{-1} to 1.3 rad s^{-1} in the experiment of Fig. 1. Immediately after Ω is changed, the lower layer is spun out towards the wall by a bottom Ekman layer and the interface falls at the axis of rotation. Within a couple of rotation periods (10–20 s), waves attain very large amplitude and can be observed when looking horizontally through the container. Such observations, as well as closed-circuit video monitoring of markers floating on the free surface, reveal that closed eddy

circulations form as the waves reach maximum amplitude. Waves and eddies then redistribute mass and angular momentum across the radius, reducing vertical shear and lifting the interface at the axis to well above its initial height. Without a sufficient interfacial shear to sustain them, the waves and eddies are rapidly dissipated by Ekman suction over a time of 10^2 rotation periods. However, isobaric surfaces must still be curved and diffusion again proceeds to slowly build up a mean azimuthal flow and vertical shear. The upper layer motion is clockwise relative to the container, which rotates in the anticlockwise sense. Hence the flow increases the curvature of density surfaces and further stimulates forcing due to the Eddington-Sweet mechanism.

After a period during which the system settles down, the flow in the experiment of Fig. 3 is stable for long periods of time (~ 5 h or 4,000 rotation periods), but is punctuated at regular intervals by relatively short bursts (lasting ~ 400 rotation periods) of unstable waves and eddies. Instability seems to occur whenever the vertical shear exceeds a magnitude beyond which release of potential energy by azimuthal waves overcomes dissipation of perturbations (E^2/Ro becomes small enough). It then causes a rapid readjustment of the mean circulation (taking as little as 150 rotation periods in the case shown). The cycle is repeated for as long as there is a sufficiently strong forcing: both baroclinic waves and long-period oscillations of the mean flow die out only when the interface becomes very thick and concentration gradients very small. The shortest period for oscillations of the mean flow found in any experiment is 1,100 rotation periods, although a wider range of conditions needs to be investigated.

The different rotation rate is not in itself significant in those experiments perturbed by a small change in Ω , as experiments that begin with the higher value of Ω but with other parameters equal also behave in the manner shown on Figs 1 and 3, with waves persisting in a continuous fashion until a change in Ω is impressed on the system. Thus, two flow regimes can occur under a given set of parameter values and in a given experiment. The regime realized must be dependent on the initial conditions or history of the flow.

Both the multiplicity of flow regimes and the possibility of energy release in short periodic bursts may be of relevance to circulation and heat transport through radiative zones in stellar interiors, where Eddington-Sweet circulations caused by thermal gradients have been predicted to be significant^{11,12}, but where only the stable and continuously unstable flow regimes have been considered. The possibility of a regime involving large fluctuations in mean circulation on timescales of the order of 1,000–5,000 rotation periods suggests the possibility of periodic variations of solar energy output on scales of tens to hundreds of years (using a rotation period for the Sun of 25 days). In oceanic circulation, the effects of other energy sources such as surface wind stress and meridional temperature gradients are expected to dominate over those of Eddington-Sweet circulations. However, on the scale of ocean basins, these forces too drive unstable baroclinic flows⁴ in which the interaction of nonlinear instability and mean flow might lead to multiple flow regimes or circulations fluctuating on long timescales. Again, if forcing and dissipation are such that mean flow fluctuations do occur, the oscillation period must scale with the rotation period of the system and our experiments indicate timescales of 3–15 yr. Data on the intensity of western boundary currents are insufficient to test for such fluctuations.

Garnet phase of MgSiO_3 , filling the pyroxene-ilmenite gap at very high temperature

Takumi Kato* & Mineo Kumazawa†

* Department of Earth Sciences, Nagoya University, Nagoya, Japan

† Department of Geophysics, University of Tokyo, Tokyo, Japan

Melting experiments on MgSiO_3 , the major constituent of the Earth's mantle and planetary interiors, have now been conducted at a static pressure of 20 GPa. These experiments reveal the presence of a new garnet-like non-cubic phase of MgSiO_3 , which melts congruently at 2,250 °C. This new silicate phase and its stability have significant implications for mantle mineralogy, chemical fractionation by partial melting and also for the occurrence of aluminium-deficient cubic garnet (majorite) in shocked meteorites. These high-pressure experiments at temperatures $>2,000$ °C have been made possible by the development of a large-volume high-pressure device at Nagoya University^{1–4}.

The high-pressure and high-temperature experiments were carried out using an MA8-type high-pressure apparatus^{1–4} and were made under a fixed ram load, which generated a pressure of 20 ± 2 GPa. To generate a very high temperature constant enough to melt silicates in a high-pressure cell, a composite of tungsten carbide and diamond was used for the heating element. The run temperature was measured by a W/W26%Re thermocouple, the hot junction being in contact with the graphite sample capsule. A powder of synthetic orthoenstatite was used for the starting material. Heating was limited to a few minutes to avoid contamination of the run product with the pressure medium, which was made of sintered MgO. Thin sections for observation by microscope and electron microprobe were prepared from the samples (~ 1 mm³), which were recovered after isobaric quenching following pressure release.

The run product at 1,760 °C, which show a granular texture indicating that recrystallization occurred in the solid state, can be identified by powder X-ray diffraction as the ilmenite phase of MgSiO_3 . The run product at 2,000 °C shows a more finely grained texture and consist of crystals with very low birefringence. The preservation of the starting composition can be

Fig. 1 Infrared absorption spectrum of non-cubic garnet of MgSiO_3 (1.8-mg sample in 190-mg KBr). The arrows at the top indicate the peak positions for majorite observed by Jeanloz¹¹ and for pyrope garnet observed by Moore¹². The present data show a similarity to those of two cubic garnets except for the presence of mode splitting.

Fig. 3 Phase diagram for the composition of MgSiO_3 . The stippled region is the pyroxene-ilmenite gap in polymorphic transition in MgSiO_3 . The melting curve is drawn after ref. 17 below 5 GPa, and is extrapolated to higher pressures. OPx-CPx boundary is after Kanzaki (unpublished data). Il-Pv boundary is after ref. 20. Other phase boundaries are arbitrarily drawn to fit the experimental observations¹⁸⁻²⁰ and phase rule.

confirmed by electron microprobe analysis, which indicates $\text{MgO} = 50.5 \pm 1.0$; $\text{SiO}_2 = 49.5 \pm 1.0$; $\text{Al}_2\text{O}_3 < 0.1$ in mol%. The pattern of powder X-ray diffraction generally fits that of pyrope garnet (ASTM 15-742), although the peaks shift towards a low diffraction angle and some of them show splitting. A garnet phase with a low crystallographic symmetry has been reported in some silicates and germanates, for example, high-pressure polymorphs of MnSiO_3 (ref. 5) CdGeO_3 (ref. 6) and CaGeO_3 (ref. 7) with tetragonal symmetry. The observed peak splitting indicates that the present garnet-like non-cubic phase (referred to hereafter as non-cubic garnet) is probably isomorphic to tetragonal MnSiO_3 , and different from majorite, an aluminium-deficient cubic garnet found in shocked meteorites^{8,9}. The powder X-ray diffraction data for the non-cubic garnet of MgSiO_3 are tentatively classified as having tetragonal symmetry (Table 1). The mode splitting is so small that detailed assignment may involve some ambiguity; the uncertainty in lattice parameters is of the order of $\pm 0.01 \times 10^{-10}$ m. Sawamoto and Kozaki¹⁰ report lattice parameters of $a = 11.472 \times 10^{-10}$ m, and $c = 11.398 \times 10^{-10}$ m, and suggest that the distortion of cubic garnet of MgSiO_3 to non-cubic phase is associated with a density

increase of about 1%. They are now trying to synthesize large single crystal samples for more accurate characterization of the crystallography.

Infrared spectral measurements of this phase and the result are plotted in Fig. 1 with the peak positions reported by Jeanloz¹¹ for natural majorite, $(\text{Mg}_{0.79}, \text{Fe}_{0.21})\text{SiO}_3$, and those reported by Moore *et al.*¹² for natural pyrope garnet. The data indicate mode splitting in this low-symmetry garnet.

Figure 2 shows a photomicrograph of the run product at 2,250 °C, in which clinopyroxene and non-cubic garnet are identified by powder X-ray diffraction. Figure 2b consists of non-cubic garnet crystals and Fig. 2a of clinopyroxene crystals. Both minerals show granular texture, while the right-hand side consists of a clinopyroxene and non-cubic garnet assemblage with a fine fibrous texture, which indicates quenching from the melt at high pressure. The electron microprobe analysis shows the same composition ($\text{MgO} = 50.4 \pm 1.0$, $\text{SiO}_2 = 49.0 \pm 1.0$, $\text{Al}_2\text{O}_3 = 0.6 \pm 0.3$ mol%) in these three phases (clinopyroxene, non-cubic garnet and melt). A little contamination during heating by H_2O and dopants from the pressure medium material has been found in the present system by Kato and Kumazawa⁴. Contamination of alumina is crucial in synthesizing the Al_2O_3 -free garnet. However, its content is so small that the phase stability may not seriously be affected. A small amount of H_2O should have little effect on the melting mode in this system. The above observations indicate that the experimental conditions (20 GPa, 2,250 °C) are very close to the triple point of clinopyroxene, non-cubic garnet and isochemical melt. Above this triple point, MgSiO_3 melts congruently at higher pressures.

The presence of alumina-deficient iron-magnesium garnet (majorite) in shock-metamorphosed meteorites has indicated

the possibility of its formation in pure MgSiO_3 garnet at high pressures and high temperatures. Ringwood and Major¹³ have reported the synthesis of garnet with a composition of $\text{Fe}/\text{Fe} + \text{Mg} = 0.25$ and $\text{Al}_2\text{O}_3 = 1.3$ mol % at 1,000 °C and above 25 GPa. Akaogi and Akimoto¹⁴ found that, in the enstatite (MgSiO_3)-pyrope ($\text{Mg}_3\text{Al}_2\text{Si}_2\text{O}_{12}$) system below 1,200 °C, at least 5 mol % Al_2O_3 is required to stabilize garnet. We have confirmed the expected formation of alumina-free garnet of MgSiO_3 at much higher temperatures than the previous studies. The synthesized garnet is not cubic but of lower symmetry. In some meteorites, cubic majorite garnet occurs in association with glass and high-pressure phases of orthosilicate (spinel and modified spinel)¹⁵, suggesting that crystallization involves melting at high pressures. This phase assemblage suggests that pressure and temperature conditions of majorite formation are close to those of the present experiment. The only difference between majorite garnet and the present non-cubic phase is the composition of $\text{Fe}/\text{Mg} + \text{Fe}$. Therefore, we anticipate the future finding of non-cubic aluminium-free garnet instead of cubic majorite in shocked enstatite chondrites (E) and bronzite chondrites (H), which have low $\text{Fe}/\text{Mg} + \text{Fe}$ in silicate phases. The detailed relationship between the cubic and non-cubic garnets is an important problem to be studied in order to clarify quantitatively the conditions prevailing in majorite-bearing meteorites.

The pressure-induced phase transitions in magnesium silicates (Mg_2SiO_4 and MgSiO_3) have been extensively studied because of their importance for investigating the nature of the Earth's mantle¹⁶. The transition in MgSiO_3 at ~1,000 °C is: orthopyroxene (OPx) → clinopyroxene (CPx) → modified spinel (MS) + stishovite (St) → spinel (Sp) + St → ilmenite (Il) → perovskite (Pv), and it possesses a gap between CPx and Il in polymorphic transition. In contrast, the transition in Mg_2SiO_4 shows a simple mode: two steps of polymorphic transition followed by a disproportionation reaction: olivine → MS → Sp → Pv + St. The disproportionation reaction of CPx involving stishovite, followed by the recombination reaction to Il, is poorly understood. The stability field of the new non-cubic garnet borders those of CPx and Il, all in the polymorphic relation, and the non-cubic garnet fills the gap between CPx and Il in the polymorphic transition of MgSiO_3 at high temperature. Therefore, MgSiO_3 has five polymorphic phases, OPx → CPx → Gt* → Il → Pv, in continuous sequence with increasing pressure (Gt* denotes non-cubic garnet). The presumed phase relation for MgSiO_3 composition is shown in Fig. 3, which summarizes the latest experimental data¹⁷⁻²⁰. The two phase assemblages involving stishovite (stippled area in Fig. 1) at the lower temperatures may be interpreted as a result of the abnormally high density and low entropy of stishovite.

We note several important implications of the present result for the constitution of the Earth and planetary interiors. The congruent melting of MgSiO_3 persists continuously from pyroxene to perovskite through non-cubic garnet, so that the pyroxene-stoichiometric phase remains as a major solid phase in the partial melting process throughout the mantle, regardless of the alumina and other minor elemental concentrations of the candidate material. Because the density of garnet is expected to be larger than the silicate melt throughout the upper mantle²¹, it may sink, thereby constituting the bottom of the upper mantle. The fractionation of garnet could have an important role in the formation of the layered structure in the mantle.

We thank H. Sawamoto, M. Kato, E. Ohtani and M. Kanzaki for discussion and advice, D. Nakamura for help on infrared absorption spectroscopy and Bob Geller for comments.

Neogene history of the calcite compensation depth and lysocline in the South Pacific Ocean

David K. Rea

Oceanography Program, Department of Atmospheric and Oceanic Science, The University of Michigan, Ann Arbor, Michigan 48109, USA

Margaret Leinen

Graduate School of Oceanography, The University of Rhode Island, Narragansett, Rhode Island 02882-1197, USA

The depth-time pattern of calcite accumulation recorded at Deep Sea Drilling Project (DSDP) sites beneath the oligotrophic subtropical gyre in the south-east Pacific Ocean allows us to define here both the calcite compensation depth (CCD) and the lysocline. The Neogene CCD history is one of shoaling before 15 or 20 Myr and subsequent deepening to the present level of 4,100 m. A broad zone of increased calcite dissolution, 600 m thick, formed during early to middle Miocene time and has remained. This zone, the lysocline, denotes an important change in ocean chemistry and may reflect either an increase in the volume of more corrosive deep water beginning about 18 Myr and reaching steady state by 14 Myr, the time of rapid ice build-up in Antarctica, or an increase in calcite rain rate caused by an increase in surface-water productivity.

Early workers in marine geology realized that throughout most of the deep ocean the calcium carbonate microfossil tests generated in surface waters dissolved before they could be incorporated into the sediments¹. Experiments in the Pacific by Peterson² and Berger^{3,4} showed that calcite dissolution did not increase linearly with depth but that little dissolution occurred above about 3,500 m and rapid dissolution occurred at greater depths. This depth zone of rapidly increasing dissolution rate is the lysocline^{4,5} and that depth at which the dissolution rate of calcite matches the supply rate, and below which there is no net CaCO_3 accumulation, is the CCD^{6,7}.

Studies of piston cores⁸ and surface sediments⁹ from the South Pacific have shown the present CCD to be at ~4,100 m depth, and the top of the lysocline near 3,500 m. Heath¹⁰ studied calcium carbonate deposition in the equatorial Pacific and inferred changes in the CCD through Cenozoic time. Berger¹¹ first incorporated seafloor subsidence history into Pacific CCD studies, using an empirical age-depth curve similar to that compiled by Sclater *et al.*¹² Results of this study of equatorial Pacific sediments gave the first reasonable estimate of the equatorial Pacific CCD history. An important event in this history was the rapid deepening of the CCD from ~4,000 to 4,800 m at 35-40 Myr. Van Andel and co-workers used empirical subsidence curves and DSDP data to determine the CCD histories of the equatorial and non-equatorial Pacific¹³⁻¹⁵. Their results refined those of Berger for the equatorial Pacific and

Fig. 1 Index map of the South Pacific showing sites used to construct the subsidence, CCD, and lysocline history of the region.

showed that CCD has been ~600 m shallower (4,000–4,200 m) since the early Oligocene in areas 10° or more north and south of the Equator.

We have determined the history of CaCO_3 deposition in the South Pacific based on data from the site chapters in the Leg 8 (ref. 16), Leg 34 (ref. 17) and Leg 92 (ref. 18) DSDP Initial Report volumes, converting the other data to the Leg 92 biostratigraphy. For each of the eight sites analysed (Fig. 1) we determined intervals of CaCO_3 deposition at rates typical of oligotrophic oceans, intervals over which there was an order-of-magnitude reduction in the mass accumulation rate of CaCO_3 -rich sediments, and the times at which CaCO_3 accumulation stopped¹⁹. The latter is a functional definition of the sedimentary CCD⁹. We presume that the large decrease in rate records the influence of the lysocline. The times of these changes are plotted along the subsidence curves¹⁹ and produce the first reconstruction of separate histories of the CCD and lysocline in the Pacific (Fig. 2).

The eight sites chosen for this study provide a generalized history of the lysocline and the CCD. Site 601 has always been above the lysocline. Sites 598 and 599 are now below the lysocline and above the CCD; Sites 319 and 597 have passed through both the lysocline and the CCD. The two oldest sites, 75 and 321, passed through the CCD abruptly with no evidence of reduced calcite accumulation rates before reaching the CCD. Site 320 was spot-cored; the youngest calcareous sediments recovered there are 15 Myr old. Nonetheless, the reasonably good agreement between the CCD from Site 597 and the maximum age of the transition through the CCD at 320 suggests that these sites passed through the CCD at about the same time.

The CCD in the South Pacific was at ~4,200 m in late Oligocene time, shoaled ~500 to a depth of 3,700 m in the middle-early Miocene, and has deepened since then to the present depth of ~4,100 m (Fig. 2). This history is similar to that determined by van Andel *et al.*¹⁵ for the subtropical and temperate Pacific.

The absence of a zone of decreased preservation²⁰ or reduced CaCO_3 accumulation above the CCD at Sites 75 and 321 suggests that the lysocline was not well developed before 20–17 Myr. It then developed and shoaled to 600 m above the CCD by 13.5 Myr. This 600-m dissolution zone (shaded in Fig. 2) has been present ever since. Linear sedimentation rates for CaCO_3 -rich sediment above the lysocline at Sites 597, 598, 599 and 601 and above the CCD at Sites 75 and 321 are all ~3–10 m Myr^{-1} . Site 319 had higher rates: 11 m Myr^{-1} just above the CCD and 35 m Myr^{-1} for older, shallower sediments¹⁹.

All investigations of the Cenozoic history of the CCD have shown a shoaling of the CCD from the middle Oligocene to middle or late Miocene time, followed by a younger deepening, broadly similar to the information shown in Fig. 2^{15,21–23}. A rise in the CCD must reflect some combination of (1) increased CO_2 content, hence corrosivity, of deep waters, reflecting either

Fig. 2 CaCO_3 accumulation record plotted on age–depth curves for each site. Squares are 1 Myr $\times$ 100 m and provide an indication of accuracy. The shaded region indicates the depth zone of the lysocline. Solid line, CCD; dashed line, lysocline.

stagnation or enhanced input of organic carbon, and (2) reduced input of biogenic CaCO_3 to the deep ocean. The ultimate causes of changes in these parameters have been related to: the rate of formation of oceanic bottom water; the nature of shelf/basin depositional fractionation which depends largely on sea level; and sea-surface biological productivity of calcium carbonate and organic carbon. Oxygen isotope data suggest that the middle Cenozoic is characterized by constant or perhaps even declining ice volume^{24,25}, hence only minor changes in the production rate of bottom water may have occurred then. Sea level rose gradually from the mid-Oligocene to the mid-Miocene²⁶, consistent with a shoaling CCD, but as the sudden, large mid-Oligocene sea-level fall does not affect the CCD, it seems inappropriate to invoke the ensuing gradual rise of sea level. We therefore agree with the view^{15,22,23} that, during times of constant ice volume, sea-surface biological productivity exerts the dominant control of the CCD. The problem remains complex, however, because factors such as total carbonate supply to the sea floor¹⁵, the amount of non-calcareous, siliceous productivity²⁷, and how or why productivity changes during times of relatively uniform oceanic and atmospheric circulation, are not well understood on a global scale.

Van Andel *et al.*¹⁵ have suggested that the lysocline may be related to the volume of corrosive deep water. If this is the case, our data suggest an increase in this volume which, within the accuracy of our data, occurred during the same time span as the inferred ice build-up on Antarctica, 16.0–12.4 Myr (oxygen-isotope stratigraphy from ref. 28; foraminifer zonation and timescale from ref. 29). We note, however, that the present lysocline does not correspond to any water mass boundaries in the Pacific. More recently, Broecker and Peng³⁰ have suggested that the thickness of the zone of rapid CaCO_3 dissolution between the lysocline and the CCD varies directly with the downward flux of calcite. If so, the early Miocene separation of the lysocline and CCD may be related to increased surface-water productivity. There exists ancillary evidence supporting increased equatorial productivity of both calcareous¹⁵ and siliceous²⁷ organisms then.

We thank the sedimentologists and palaeontologists on board the *Glomar Challenger* during Leg 92 for their efforts which produced much of the present data. N. Pisias and W. Berger made several useful comments and suggestions.

Fig. 1 Bathymetry (from seabeam swath-mapping⁴) and location of Deep Sea Drilling Site 599 on the west flank of the East Pacific Rise. This site, along with the other DSDP Leg 92 sites, was the first on the East Pacific Rise to be drilled using the hydraulic piston corer, which minimizes sediment disturbance during the coring process.

Downslope transport of metalliferous sediments along the East Pacific Rise during the late Miocene

The distribution of metalliferous sediments next to active spreading centres has scientific and economic interest¹. Although metal-rich waters emanating from active hydrothermal vents have been traced in intermediate level water masses far beyond the ridge crest², the greatest concentrations of metal oxides in sediments occur near the vents³. There, however, it is conceivable that the oxides may be redistributed and possibly further concentrated by redeposition, resulting in misconceptions of the age and relative timing of hydrothermal pulses. Here, we document microfossil evidence of stratigraphical inversion and redeposition of Upper Miocene (Messinian) sediments cored at Deep Sea Drilling Project (DSDP) Site 599 on the East Pacific Rise (EPR). This suggests that where reworking can be confirmed, care should be taken not to correlate directly the occurrences of the metalliferous sediments with apparent coeval pulses of hydrothermal activity or enhanced seafloor spreading rates.

Hole 599 (19°27.09' S, 119°52.88' W; water depth = 3,654 m), located ~600 km west of the present ridge crest, was drilled in a small basin surrounded by a region of low relief with abyssal hills ranging from 200 to 300 m in height (Fig. 1). This site yielded some 41 m of mostly Upper Miocene clay-bearing to clayey calcareous oozes with a basement age of 8.1-8.6 Myr (ref. 5). The lower 31 m of the section is strikingly layered, consisting of alternating light (mostly yellowish brown to dark yellowish brown) and dark (mostly dark reddish brown) coloured layers tens of centimetres thick (Figs 2, 3). The colour variations are the result of changes in the relative amounts of calcium carbonate (70-80% in light coloured sediments, 55-70% in dark coloured sediments⁵) and a noncarbonate fraction which is primarily clays and ferruginous grains. The clays are mixtures of poorly crystalline smectites and amorphous oxides. The ferruginous grains, which range in size from 10 to 100 µm, are a metalliferous hydrothermal component which has been described by Leg 34 scientists as red-brown to yellow-brown, semi-opaque oxides (RSOs)⁶.

The strongly layered portion of the section is dated between

Fig. 2 Sections 1-5 of DSDP Core 599-3 showing alternations of light (L), dark (D), and intermediate (I) coloured lithologies within the Messinian clayey nannofossil ooze sequence (see key in Fig. 3 for detailed colour descriptions). The darker lithologies contain less carbonate and more hydrothermal metalliferous components than do the lighter lithologies. Note the sharp contact (dark over light) at 21 cm in section 599-3.

Fig. 3 Correlation of colour, grain size and calcareous nannofossil assemblages in a portion of the Messinian section at Site 599. The darker and coarser grained, redeposited metalliferous sediments contain reworked microfossil assemblages which indicate apparent ages up to 2.5-Myr older than the actual age of the sequence.

5.0 and 8.6 Myr (ref. 7) using the calcareous nannofossil zonation of Okada and Bukry⁸ as calibrated against time by Haq⁹. The bulk of that section (12.3–30.7 m), however, falls within the *Amaurolithus primus* Subzone (CN9b) of the *Discoaster quinqueramus* Zone which, according to Haq⁹, spans the Messinian Stage (6.7–5.4 Myr). That age determination is not immediately apparent, however, because this part of the section contains anomalous stratigraphical inversions of coccolith assemblages with older assemblages (represented in Fig. 3 by zones of lower numbers or letters) interbedded with the younger sediments of Subzone CN9b. The older assemblage of the 'apparent' Zone CN8 ('apparent age' = 9.2–8.1 Myr) is characterized by many *Minylitha convallis* and few *Discoaster neohamatus*, whereas the younger assemblage of Subzone CN9b is characterized by many *Discoaster surculus* and few *Amaurolithus primus*. The older assemblages are considered to be reworked and/or redeposited. There is little detectable mixing between these assemblages.

Detailed studies were carried out on Core 599-3 where the colour banding is pronounced (Fig. 2). As indicated in Fig. 3, there is a strong correlation between the occurrence of the older coccolith assemblages and the dark or intermediate-coloured metalliferous sediments⁷. There is also a strong correspondence between colour and grain size of the sediment, with the darker sediment containing coarser material¹⁰ (Fig. 3). These correlations are particularly evident at the sharp contact in Section 599-3-3 at 21 cm. We conclude that this contact marks the base of a turbidite which transported or concentrated sediments with an anomalously high content of metalliferous components into the basin. As indicated for other parts of the section depicted in Fig. 3, this process of redeposition could well account for much of the hydrothermal material deposited in this portion of the section recovered at Site 599.

The juxtaposed coccolith assemblages correlated above with

textural characteristics of the sediments, which include examples of graded bedding, provide strong evidence for downslope processes active on the EPR during the late Miocene. The timing of these mass movements correlates closely with the Messinian sea-level drop and intensified current activity which have been widely recorded in many ocean basins^{11–13}. Displaced shallow-water fossils of a similar origin are also recorded in many other tropical and sub-tropical Pacific DSDP sites^{14–16}, therefore the triggering mechanism for the turbidites at Site 599 may be related to erosion by intensified currents. An alternate explanation is tectonic instability associated with possible increased seismic activity along the EPR. This, in turn, might be coupled with accelerations in volcanic discharge and seafloor spreading rates which are thought to have peaked in the Pacific at ~5 Myr (ref. 17). These speculations are further elaborated in more extended discussions to be described elsewhere^{7,10}. By either mechanism, however, the concentration and distribution of the metalliferous sediments seem to be appreciably affected by processes of redeposition at this locality. Redistribution of these sediments was probably enhanced by their relatively low specific gravity and by the topographic relief at this site (Fig. 1). Should a similar configuration of strongly banded sediments with sharp basal contacts beneath the dark coloured layers be encountered elsewhere, redeposition might reasonably be suspected. If reworking and/or redeposition is suggested by palaeontological evidence, care should be taken not to correlate directly the increased concentration of metalliferous sediments with episodes of heightened hydrothermal activity or enhanced seafloor spreading rates.

We thank Philip Froelich and Jörn Thiede for their reviews of the manuscript and the NSF for financial support. All samples related to this project were made available through the Deep Sea Drilling Project.

'Strangelove ocean' before the Cambrian explosion

Kenneth J. Hsu*, Hedi Oberhänsli*, J. Y. Gao*,

The Palaeozoic and Mesozoic eras were terminated by faunal changes involving mass extinction of the old and explosive evolution of the new fauna, but the fossil record shows only a Cambrian Explosion at the end of the Precambrian. Stanley speculated that the explosion was only possible after the ubiquitous algae community had been largely eliminated¹; ecological niches were thus liberated for explosive evolution. If the Cambrian Explosion were preceded by a mass mortality (or by a mass extinction), such an event should leave a record in the form of geochemical anomalies. We have undertaken a search for geochemical anomalies at the Precambrian/Cambrian contact. We report here the discovery of a sharp negative carbon-isotope shift in the carbonate of a clay immediately above a marker in the Precambrian/Cambrian boundary, the China C marker, and interpret this signal as evidence of sudden decrease in fertility before the Cambrian explosion of invertebrate evolution. The discovery suggests that the Precambrian/Cambrian boundary might be defined by an event-marker at a palaeontologically correlative horizon.

Investigations of the Cretaceous/Tertiary boundary reveal that the boundary event left a signature in an iridium anomaly and a carbon isotope anomaly^{2,3}. The dual Ir- $\delta^{13}\text{C}$ anomalies were also found recently in a Permian/Triassic boundary clay⁴. The exact placement of Precambrian/Cambrian boundary has not yet been established. Chinese scientists have suggested three datum levels as candidates: China A marks the first appearance of inarticulate brachiopods and China B defines the base of the *Paragloborilu Siphonogonuchites* Zone, characterized by a more diversified shelly fauna. The third, or the China C marker, is slightly above the China B (Fig. 1), and defined by a remarkable lithological change from a phosphate-rich rock to a black shale. This horizon marks the base of a formation containing the first trilobites⁵, and has been correlated for thousands of kilometres across South China.

Following the discovery in 1982 of an iridium anomaly in a black shale above the China C marker (C. C. Woo, personal communication) one of us (K.J.H.) took samples across the iridium-rich horizon. Six samples from a 12-m section were obtained at the Type Locality for the Precambrian Sinian Group in the Yangtze Gorge section, ~20 km west of Ichang, Hupeh Province, China. Analysis confirmed the presence of higher

Fig. 1 Stratigraphical columns across a proposed Precambrian/Cambrian contact (China C marker) at two localities in south-west China. Iridium anomaly has been identified in the boundary clay at the Yangtze Gorge locality. The Q and KH numbers are sampling numbers. The Q samples have been obtained at 2-cm intervals apart. KH samples were taken for a reconnaissance study. Not shown are the densely spaced samples from the Yangtze locality. China B marks the base of Dahai.

iridium and osmium contents in a black clay immediately above the China C marker. Also found was a carbon-isotope anomaly at the iridium-enriched horizon (Fig. 2).

The discovery prompted us to resample across the China C marker in 1984 to produce a more systematic investigation. Fifty-three samples were taken from the Yangtze Gorge locality near the marker at intervals spaced 2-cm apart. Some 100 samples were taken from the Kunyang Mine with 2-cm sampling intervals, not only across China C, but also across China A and China B markers. The close sampling was done to define precisely the carbonate-isotope anomaly, and to determine whether the anomaly is a signal or a random variation. The stratigraphy of both localities has been described in detail elsewhere^{5,6}. Note that the first trilobite specimens were collected in a calcareous shale within 1 m above the China C marker at the Yangtze locality, but at a horizon some 10 m higher at Kunyang.

The isotope analyses were carried out at ETH Zurich. The phosphatic rocks contain 90% carbonate and the black shale contain between 8 and 26% carbonate, which is mainly dolomite. A thin seam of black shale immediately above the China C marker can, however, be considered a boundary clay layer; the sample at the Kunyang Mine contains 0-4% carbonate, and the one at the Yangtze Gorge locality is practically carbonate-free, thus yielding no isotope results.

The $\delta^{13}\text{C}$ values of the dolomite at the two localities are shown by Fig. 3. The background values are slightly more negative at

Fig. 2 Geochemical anomalies across the China C marker at Yangtze locality.

the Yangtze Gorge than those at the Kunyang locality. Note the sharp anomaly of $\sim 5\%$ more negative values exactly at a horizon immediately above the China C marker. This anomaly is present at both localities, which are $\sim 1,000$ km apart.

The sedimentation rate of the Cambrian black shale cannot be accurately determined. Chinese scientists estimated an average sedimentation rate of <10 m Myr^{-1} , for the Cambrian rocks, based on the thickness of the Cambrian strata ($<1,000$ m) of the Yangtze Gorge Section⁶ and the duration of the Cambrian Period (>100 Myr). Assuming such a rate, the isotope shift at the China C datum should have taken place within 2,000 yr. The anomaly is thus a sharp perturbation, comparable in its magnitude and sharpness with those found across the Cretaceous/Tertiary and Permian/Triassic boundaries.

Samples across the China A and China B markers at Kunyang are still being analysed. We have not yet found iridium nor carbon-isotope anomalies across those boundaries.

The values of $\delta^{13}\text{C}$ in marine carbonate is influenced by many factors, such as terrestrial influx, ocean-atmosphere exchange, and biological productivity⁷. Thousands of analyses of deep-sea drill cores indicate that carbonate-isotope values of ocean sediments do not vary rapidly with time, on account of the very large reservoir of dissolved carbonate atoms in ocean waters. No sharp global anomalies ($2\text{--}4\%$ in 10^3 or 10^4 yr) have ever been observed except across the Cretaceous/Tertiary boundary, although long-term variations with anomaly values up to 4% over a $10^6\text{--}10^7$ -yr period are not uncommon.

Sharp perturbation of ^{13}C values in sediments has been related to ocean fertility. Natural fractionation of carbon isotopes by biological activity is well known. Carbon-12 atoms are preferentially used by living organisms, so that the carbon-13 atoms in dissolved carbonates are enriched in surface waters where the planktons flourish. This phenomenon has been confirmed by isotope analyses of dissolved carbonates in ocean and lake waters^{7,8}. Sudden changes in biological productivity produce $\delta^{13}\text{C}$ anomalies in surface water. Two types of anomalies have been recognized, namely a positive anomaly of 'fertility perturbation' and a negative anomaly or 'Strangelove perturbation'.

The 'fertility perturbation' was discovered by McKenzie at Lake Greifen⁹. There was a positive anomaly of 4.5% in the inorganic $\delta^{13}\text{C}$ in the surface waters during late July and August (months of high fertility, when green algae production reaches a maximum) (Fig. 2). No such anomaly was detected in the inorganic carbon of the bottom sediments. In fact, a slight negative anomaly of $<1\%$ was detected in September, the month after the harvest, when the light carbon in bottom waters was relatively enriched because of the decay of dead organisms.

The exact opposite type of perturbation has been found at Cretaceous/Tertiary and Permian/Triassic boundaries^{3,4}. In ancient as in modern ocean waters, the inorganic carbon of surface waters is normally enriched in carbon-13. The $\delta^{13}\text{C}$ is $\sim 2\%$, more positive than that of bottom waters because of the steady production of plankton. Fertility is a normal state. After events such as those marking era-boundaries, the environmental pollution may have been such as to reduce or to suppress

Fig. 3 Strangelove perturbation across the China C marker. a, Kunyang Mine locality, Yunnan Province. b, Yangtze Gorge locality.

plankton production for thousands of years. This hypothetical state of ocean, almost devoid of living organisms, has been called the 'Strangelove Ocean' (refs 8, 9). The geochemical expression of this ocean is a perturbation in the $\delta^{13}\text{C}$ value of planktonic sediments: when the carbon-isotope fractionation by biological activity ceases, a mixing of surface and bottom waters should produce a carbon-isotope composition that is consistent from the top to the bottom of the water column. Consequently, the planktonic sediments deposited during a crisis should have a $\delta^{13}\text{C}$ value similar to that in the bottom sediments, and be considerably more negative than the planktonic sediments deposited in normally fertile conditions. The presence of a Strangelove perturbation across the Cretaceous/Tertiary boundary is thus considered to be evidence of an interrupted plankton production following a boundary event⁹.

Calcareous planktons, such as foraminifera and nannoplanktons, had not yet evolved during the Precambrian. Yet Precam-

Fig. 4 Carbon-isotope anomaly related to plankton productivity. The left-hand side shows the annual variation of carbon-isotope values in dissolved carbonates of surface water (solid line) and of bottom water (dashed line) in Lake of Greifen, Switzerland. Time at the bottom is January and at the top is December. A positive perturbation in surface water is observed in July and August when the plankton fertility reaches the maximum. The right-hand side of the figure is the short-term perturbation of carbon-isotope values across the Cretaceous/Tertiary boundary at DSDP Site 524 in the South Atlantic Ocean, showing the changes in the planktonic (solid line) and in the benthic (dashed line) foraminifera. The base of the negative Strangelove perturbation coincides with the Cretaceous/Tertiary boundary, marked by an iridium anomaly; and the perturbation is believed to indicate that the biomass of ocean planktons had been drastically reduced.

brian pelagic or hemipelagic sediments contain carbonates. The carbonates were probably produced through the biological activity of planktonic organisms, such as phytoplanktons or green algae. These left no fossil skeletons, but their photosynthesis removed CO_2 from the surface water to cause carbonate oversaturation and precipitation. This process of calcite production occurs annually in the Swiss lakes¹⁰. If a catastrophe should have occurred, and resulted in suppressed plankton production in Precambrian oceans, the biological fractionation of carbon isotopes would cease. Consequently, we could interpret the large negative $\delta^{13}\text{C}$ anomaly at the 'China C datum' as a Strangelove perturbation. Geochemical anomalies thus support the theory¹ that early Cambrian evolution of multicellular life was preceded by a catastrophic destruction of the late Precambrian biomass.

Some unknown single-celled herbivores were held responsible for the destruction of the ubiquitous algal community of the Precambrian¹. The idea is not supported by palaeontological evidence, because the postulated culprit left no fossil skeletons. Furthermore, the Cambrian explosion was preceded by the evolution and extinction of the Ediacarian soft-bodied fauna¹², which could not have been vulnerable to the herbivores in ref. 1. If there was a major extinction before the Cambrian explosion, some other cause must be sought.

Note that an iridium anomaly in the black shale immediately above the China C marker has been found in many parts of South China^{12,13}. The anomalously high values up to 30 p.p.b. (parts per 10^9) Ir (ref. 12) in metalliferous sediments may have resulted from secondary enrichment, but the enrichment may have been preceded by a primary source of iridium. The possibil-

ity of a large-body impact before the Cambrian explosion must thus be considered an attractive working hypothesis.

The dual iridium $\delta^{13}\text{C}$ anomaly in a boundary clay above a palaeontological datum has only been found globally across the Cretaceous/Tertiary boundary and, in China, across the Permian/Triassic boundary. The presence of the same association of an iridium-anomaly/Strangelove-perturbation/boundary-clay above a palaeontological datum marking the first appearance of trilobites cannot be coincidental. Whatever the ultimate cause of the geochemical anomalies, the possibility that the Precambrian/Cambrian boundary is definable by an event marker is worthy of further exploration. The IGCP Project 199 on Rare Events in Geology has undertaken the task of international cooperation to ascertain if geochemical anomalies similar to those reported here can be found elsewhere.

Mass extinction among non-marine tetrapods

Michael J. Benton

Department of Geology, Queen's University of Belfast, Belfast BT7 1NN, UK

The fossil record of non-marine tetrapods (amphibians, reptiles, birds and mammals) has been described by numerous authors¹⁻³, and major ecological replacements, mass extinctions and adaptive radiations have been identified. However, most of these features of the large-scale evolution of tetrapods have been noted without numerical data of the kind assembled for marine invertebrates⁴⁻¹⁰, marine vertebrates⁷⁻¹⁰ and vascular land plants¹¹. Much has been learnt from the record of marine invertebrates, particularly about the overall patterns of diversification with time, the performance of different major taxonomic groups at different times, and the magnitude and timing of mass extinctions. The present study tests some of the general conclusions on the basis of a new compilation of data on the fossil record of terrestrial tetrapods. I show that family diversity rose with time, and in particular from the Cretaceous to the present day. There were several mass extinction events, but none of these was associated with a statistically high extinction rate. The extinction events, including the famous terminal Cretaceous extinction, were the result of a slightly elevated extinction rate combined with a depressed origination rate, and the present evidence does not support the view that mass extinctions are statistically distinguishable from background extinctions. Further, the record of non-marine tetrapods shows an increasing total extinction rate and an only marginally decreasing probability of extinction (per-taxon rate) from the late Devonian to the present, the opposite of the findings from the record of marine animals.

The present study is concerned with the fossil record of non-marine tetrapods: this includes terrestrial, freshwater and flying forms, but excludes fully marine families. A list of all the families of terrestrial tetrapods was made using the most recent taxonomic reviews, as well as secondary literature, to the end of 1984 (for details see ref. 12). A small number of extinct

Fig. 1 Standing diversity with time for families of terrestrial tetrapods. The upper curve shows total diversity with time, and six apparent mass extinctions are indicated by drops in diversity, numbered 1-6. The relative magnitude of each drop is given in terms of the percentage of families that disappeared: (1) early Permian (Sakmarian-Artinskian), 58%; (2) late Permian-early Triassic (Tatarian-Scythian), 49%; (3) late Triassic (Norian-Rhaetian), 28% (4) late Cretaceous (Maastrichtian), 14%, (5) early Oligocene (Rupelian), 8%; late Miocene (Tortonion-Messinian), 2%. The mass extinctions were produced by a combination of a slightly elevated extinction rate and a reduced origination rate. The timescale used was that of Palmer¹⁶. Three assemblages of families succeeded each other through geological time: I, labyrinthodont amphibians, anapsids, mammal-like reptiles; II, early diapsids, dinosaurs, pterosaurs; III, the 'modern' groups: frogs, salamanders, lizards, snakes, turtles, crocodiles, birds, mammals. These assemblages were defined somewhat arbitrarily to encompass those groups that dominated non-marine tetrapod faunas in the late Palaeozoic, the Mesozoic and the Cenozoic respectively. The data are not robust enough for the application of the factor analytic technique of Sepkoski⁶. Abbreviations Carb., Carboniferous; Dev., Devonian, Trias., Triassic.

Fig. 2 Total extinction rate (a) and per-taxon extinction rate (probability of extinction) (b) for families of terrestrial tetrapods. The total extinction rate increases with time according to the linear regression $y = 0.00832x + 3.497$ ($P = 0.003$; $r^2 = 0.16$), while the per-taxon extinction rate declines with time according to the linear regression $y = -0.00013x + 0.017$ ($P = 0.024$; $r^2 = 0.09$). The extinction rate data in both cases are better explained by three log linear regressions for different time divisions (these are indicated by dashed curves; see Table 1 for the equations). Extinction rates were calculated for 45 stages between the early Carboniferous and the Pleistocene: the late Devonian (Famennian) and early to middle Jurassic stages (Hettangian–Oxfordian) were excluded because of the poor fossil record within these intervals. The episodes of mass extinction determined in Fig. 1 are indicated by arrows. Abbreviations as in Fig. 1.

families were excluded from the analysis as they were based on single, often incomplete, specimens; this left a total of 730 families, of which 469 are extinct. The quality of the fossil record of terrestrial tetrapods is variable because certain kinds of environments are poorly preserved, and there is evidence that the record is particularly bad in the early and middle Jurassic, and in the mid-Cretaceous (see below). The range in geological time for each family was determined from the most recent available literature, and this was resolved to the level of the stratigraphic stage (duration 2–19 Myr; mean duration 6 Myr).

The numbers of families of terrestrial tetrapods are plotted against geological time in Fig. 1. The most striking feature of this graph is that the number of families present at any time remained at levels below about 50 until the last quarter of the Cretaceous period when the numbers of families increased to nearly 80, and the rise continued to the present total of 337 in several steps during the Tertiary. This great increase in family diversity may be partly an artefact of the fossil record which

Fig. 3 Total origination rate (a) and per-taxon origination rate (probability of origination) (b) for families of terrestrial tetrapods. The total origination rate increases with time according to the linear regression $y = 0.02008x + 6.356$ ($P = 0.001$, $r^2 = 0.21$), while the per-taxon rate declines with time according to the log linear regression, $\log y = 0.00105x - 1.582$ ($P = 0.048$, $r^2 = 0.07$). The total origination rate data are better explained by three log linear regressions for different time divisions (these are indicated by dashed curves; see Table 2 for equations). The per-taxon origination rate data did not correspond to a statistically significant linear regression, nor were significant regressions derived for different time divisions: only the late Permian to late Triassic data fell along a significant linear or log linear regression (for the equations, see Table 2). Other information is given in Fig. 2 legend.

generally improves towards the present, and of the greater research emphasis devoted to Tertiary fossil vertebrates than to earlier ones. However, a large part of the increase is probably a real biological phenomenon, as has been shown for the record of marine invertebrates.^{13,14}

The second interesting feature of this analysis is that it shows a succession of family assemblages that dominated for a time and were then replaced (Fig. 1). The first assemblage of tetrapod families—labyrinthodont amphibians, anapsids and mammal-like reptiles—dominated from the late Devonian to the early Triassic. The second assemblage—primitive diapsid reptiles, thecodontians, dinosaurs and pterosaurs—arose in the Permian and increased in diversity through the Triassic as the members of the first assemblage declined. This second assemblage dominated from the late Triassic to the late Cretaceous. The third assemblage, which includes all modern tetrapod groups—frogs, salamanders, lizards, snakes, turtles, crocodiles, birds and mammals—arose in the late Triassic, and increased in diversity

through the Jurassic and early Cretaceous. During the Cretaceous, the diversity of these modern groups was approximately equal to that of the second assemblage of dinosaurs and pterosaurs. In the latest Cretaceous, the diversity of the modern groups rose dramatically and became twice that of the dinosaurs and pterosaurs, long before the terminal Cretaceous extinction event. The modern groups were barely affected by this extinction, and their family diversity increased through the Tertiary. Members of the first assemblage reached an observed familial diversity of about 30 in the Permian, whereas dinosaur and pterosaur families reached an observed diversity of only 20–25 families in the Cretaceous.

The third part of this study concerns the occurrence of mass extinctions in the fossil record of terrestrial tetrapods. The terminal Cretaceous event, during which the dinosaurs and pterosaurs disappeared, is well known^{15–17}, and other extinctions among tetrapods have been suggested in the middle of the Permian^{18,19}, at the end of the Permian^{18,19}, at the end of the early Triassic^{18,19}, and at the end of the Triassic^{18–20}. A mass extinction may be identified at first by the observation of a drop in diversity. The general upward trend of the plot of family diversity of terrestrial tetrapods with time (Fig. 1) is interrupted by several major reductions in family diversity, in the early to mid-Permian (Sakmarian–Artinskian), the late Permian to early Triassic (Tatarian–Scythian), the late Triassic to early Jurassic (Norian–Hettangian), the late Jurassic (Portlandian), the late Cretaceous (Maastrichtian), the early Oligocene (Rupelian) and the late Miocene (Tortonian–Messinian).

These episodes of diversity decrease may not all represent mass extinctions. Two of them (early Jurassic, late Jurassic) are followed by times during which there is a very poor fossil record of terrestrial tetrapods (that is, there are no fossils known, or only one or two, from a particular stratigraphic stage). In these two cases, much of the decline in diversity, if not all of it, could be the result of the poor fossil record, and the conservative conclusion is to assume that these two are not mass extinctions. The initial part of the late Triassic to early Jurassic mass extinction began well before the poor fossil record of the early to middle Jurassic, and the earlier part is retained as an extinction event¹². The mid-Permian decline in diversity might also partially reflect a gap in the fossil record, but, again, at least the earlier part is probably a mass extinction.

The six remaining declines in diversity are listed in Fig. 1 as a percentage of the total number of families present at the start. These vary in magnitude from 2% in the late Miocene to 58% at the end of the early Permian. The first three extinctions, in the Permian and Triassic, had the greatest overall effects (falls of 28–58%), but each of these lasted over two stratigraphic stages (durations of 14, 13 and 17 Myr for extinctions 1–3 respectively). The terminal Cretaceous event had a lower overall effect (drop of 14%), but it occurred in a single stratigraphic stage (duration 8 Myr). The two Tertiary extinctions (numbers 5 and 6) had much smaller relative effects on overall diversity.

A decline in family diversity could be the result of a high extinction rate, or a low origination rate, or a combination of the two^{18,21}. It is commonly assumed that declines in diversity (mass extinctions) are caused only by a high extinction rate, and reasons are then sought to explain the 'dying off'. However, if the decline in diversity were associated with a depressed family origination rate, and the extinction rate was normal, we would have to seek other kinds of explanations.

The nature of the six terrestrial tetrapod mass extinctions was explored by an analysis of the total extinction and origination rates (simply the numbers of families dying out or appearing during a stage, divided by the duration of that stage), and the probabilities of extinction or origination (calculated for each stage as the total rate divided by the number of taxa 'at risk' or 'available', according to Van Valen's²² definition; also called per-taxon rates).

First, the total and per-taxon rates were plotted against geological time (Fig. 2) to determine whether the times of observed mass extinctions were marked by high extinction rates. Most

(5d) (Tour-Ufim) $\log_{10} y = 0.01247x + 2.054$	0.006	0.56

Probabilities of extinction were calculated using the Van Valen²² metric (that is, the number of extinctions (last appearances) in a stage, divided by the number of taxa at risk. The latter was estimated as the number of taxa at the beginning of the interval, minus half the extinctions, plus half the originations in the interval). The equations that give the highest percentage of explained sum of squares (*r*²) are listed here. Equations are given for all stages treated together, and then for a three-way division of the data, with splits in the mid-Permian (Ufim/Kaz) and in the early to middle Jurassic (Nor/Kimm). Note the absence of data for the stages of the early and middle Jurassic. The probability (*P*) of the correctness of each regression equation is also given; Kaz, Kazanian; Kimm, Kimmeridgian; Nor, Norian; Pleist, Pleistocene; Tour, Tournaisian, Ufim, Ufimian.

* *P* > 0.1 (nonsignificant results) are marked by an asterisk.

total extinction rates fell below 4 per Myr, but several rates were higher (up to 12 family extinctions per Myr), while most probabilities of extinction fell below 0.120 per family per Myr, with higher rates up to 0.240. Both graphs gave highly significant linear regressions (*P* = 0.003, *P* = 0.024; Table 1). Raup and Sepkoski⁷ suggested that mass extinction events were associated with statistically very high extinction rates (outliers above the 95% confidence envelope of a linear regression of all extinction rates), but this technique did not work for the non-marine tetrapod record. Most of the outliers (that is, stages during which extinction rates were statistically very high, for example, Pleistocene, Ufimian), did not correspond to falls in overall diversity, as they were matched by even higher origination rates. The technique also did not work when the extinction data were transformed to logarithms²³ or to square roots²⁴.

The total and per-taxon origination rates were then plotted against geological time (Fig. 3) to determine whether the times of observed mass extinctions were marked by statistically low origination rates. The graph of total origination rates (Fig. 3a) gave a highly significant linear regression (*P* = 0.001), but the graph of probabilities (Fig. 3b) did not (Table 2). Statistical tests for outliers—extremely low origination rates—did not pick out the times of mass extinction. The statistically low rates did not correspond to falls in diversity because they were matched by high extinction rates.

Thus there is no evidence in the record of non-marine tetrapods that mass extinctions are statistically distinguishable from 'background' extinctions, by having either a very high family extinction rate or a very low family origination rate. Note, however, that the time resolution in this study, as in most others

Probabilities of origination were calculated using an analogue of Van Valen's²² extinction probability metric. This, and other conventions and abbreviations, are explained in the legend to Table 1

published so far, is very coarse, and this could minimize the true size of a sudden event by averaging it out over several million years. In all cases, the declines in diversity (mass extinctions) were produced by slightly elevated extinction rates and slightly depressed origination rates. However, neither the total rates nor the probabilities were obviously different from 'normal' rates, and this statistical study points to a model of extinction events that does not distinguish mass extinctions as a discrete class of phenomena from background extinctions.

The graph of total extinction rates (Fig. 2a) shows that there was an overall rising trend with time. Most of this rise is explained by the increase in overall diversity (the more families there were, the more could become extinct in a unit of time). However, the probability of extinction (Fig. 2b) decreased with time, although by only a very small amount (0.00012 less families dying out per family per Myr; ~0.07% decline per stage). The increase in total extinction rates, and the small decrease in probability of extinction are very surprising, as the record of marine animals shows an overall markedly declining trend in both total and per-taxon extinction rates, the latter trend giving a decline of ~6.6% per stage^{7,22,25}. The graph of total origination rate (Fig. 3a) shows a rising trend with time, while the graph of probability of origination (Fig. 3b) did not yield a significant regression.

An attempt was made to find statistical models that described the data for extinction and origination rates more precisely (that is, giving a higher percentage of explained sum of squares, r^2), by splitting the data into several time intervals, and by transforming the rates into logarithms and square roots. The data set was not large enough, after refinement, for time series analysis^{10,25}, but it was found that the extinction rate data could be better described if the data were divided into three time sets: from the early Carboniferous (Tournaisian) to the mid-Permian (Ufimian), from the late Permian (Kazanian) to the late Triassic (Norian), and from the late Jurassic (Kimmeridgian) to the

Pleistocene. A set of three log linear regressions gave the best explanation of the total extinction rate data (Table 1, equations 3a-d), and the same applied to the per-taxon extinction rate data, although the third time interval was still poorly explained (Table 1, equations 5a-d). For total origination rates, three log linear regressions also provided the best model (Table 2, equations 3a-d), but the per-taxon origination rate data could not be so readily accounted for (Table 2, equations 6a-f). The best-fit regressions divide the data into three time segments (Figs 2, 3): (1) early Carboniferous to mid-Permian (rates rise sharply); (2) late Permian to late Triassic (rates fall sharply); (3) late Jurassic to Pleistocene (rates rise again).

The present analysis of the fossil record of non-marine tetrapods has shown two main points. First, none of the observed mass extinctions was caused by either very high rates of extinction or very low rates of origination. In fact, each event was associated with rates that did not differ statistically from normal background rates. Second, the total rate of extinction has risen with time from the late Devonian to the present day, and the probability of extinction has declined only marginally. The tetrapod record shows little evidence for overall improvements in the ability of organisms to 'resist' extinction—increases in darwinian fitness²².

I thank Ms Libby Lawson for drawing Figs 2 and 3.

Susceptibility to murine lymphocytic choriomeningitis maps to class I MHC genes—a model for MHC/disease associations

R. M. Zinkernagel*, C. J. Pfau*†, H. Hengartner* & A. Althage*

* Institut für Pathologie der Universität Zürich, Universitätsspital, CH-8091 Zürich, Switzerland

† Department of Biology, Rensselaer Polytechnic Institute, Troy, New York 12181, USA

Susceptibility to some human diseases is linked, albeit weakly, to major transplantation antigens (HLA) encoded by the major histocompatibility gene complex (MHC)^{1,2}. Here we have studied MHC/disease association in inbred strains of mice after intracerebral (i.c.) injection of lymphocytic choriomeningitis virus (LCMV)³⁻⁶. This route of infection leads to a lymphocytic choriomeningitis (LCM) which is not the result of direct cytopathic effects of the virus but is caused by the induced T-cell immune response: immunocompetent mice die whereas T-cell-deficient mice

survive³⁻⁶. By using two plaque variants of LCMV strain UBC (refs 7, 8), we found that susceptibility to LCM was dependent on the LCMV strain used ('aggressive' versus 'docile' UBC-LCMV) and on the various genes of the host mouse strains. In addition, susceptibility to LCM caused by docile UBC-LCMV was clearly linked to the murine major histocompatibility locus *H-2D*: in MHC-congenic C57BL/10 mice, susceptibility correlated with early onset and high activity of measurable LCMV-specific cytotoxic T cells in meninges and spleens and could be mapped to *H-2D*. This model shows that a severe immunopathologically mediated clinical disease in mice can be regulated directly by MHC genes of class I type and supports the notion that many MHC/disease associations directly reflect MHC-restricted and MHC-regulated T-cell reactivity⁹.

Mice of various strains and various *H-2* types were assayed for susceptibility to docile and aggressive UBC-LCMV injected i.c. at >8 weeks of age (Table 1). Susceptibility to LCMV depended on the general genetic background of the injected mice: Swiss and a few B10 mice were susceptible to both UBC-LCMV substrains; most B10 and BALB mice were susceptible to aggressive but resistant to docile LCMV; C3H and CBA mice were susceptible to docile and relatively resistant to aggressive LCMV. In B10 mice, susceptibility to LCM caused by docile UBC-LCMV was found to be regulated by *H-2*; B10.G mice with the *q* haplotype, including (B10.BR × B10.G) (*H-2^k* × *H-2^q*)_{F1}, were susceptible in a dominant fashion, whereas mice of haplotype *H-2^k*, *H-2^d*, *H-2^b* and *H-2^a* and most others, were resistant. *H-2*-dependence of susceptibility to LCMV was also seen in DBA mice. DBA/1 mice (*H-2^q*) were susceptible to both strains whereas *H-2* congenic DBA/2 with *H-2^d* were resistant to both aggressive and docile LCMV. In C3H mice, *H-2* did not significantly influence susceptibility independent of *H-2^q* or *H-2^k*. Swiss inbred SWR/J (*H-2^q*)¹⁰, were highly susceptible to both UBC-LCMV strains. Thus, susceptibility to LCM depends on the virus variant injected and on the multiple genes of the host that influence resistance or susceptibility (such as interferon and macrophage resistance^{11,12}), only one gene being encoded in the MHC.

The role of various *H-2* regions in susceptibility to LCM was tested in several MHC-congenic inbred strains of mice with the B10 background (Fig. 1). B10.G(*H-2^q*: *K^q*, *I^q*, *D^q*), B10.AQR(*H-2^q*: *K^q*, *I^q*, *D^q*), B10.T(6R)(*H-2^q*: *K^q*, *I^q*, *D^q*), B10.AKM(*H-2^m*: *K^k*, *I^k*, *D^q*) and B10.BR(*H-2^k*: *K^k*, *I^k*, *D^k*)

Fig. 1 Groups of five mice of various *H-2* congenic B10 murine strains were injected with ~500 PFU of docile (—) or aggressive (---) UBC-LCMV i.c. and cumulative mortality was monitored. The results shown were obtained with mice purchased from OLAC, Bicester, UK, but identical results were found with mice from the Tierspital, University of Zurich, and from Jackson Laboratory, USA. Mice were between 6 and 18 weeks old. The alleles of the *H-2K*, *I* and *D* regions are shown beneath the strain names

Mice (8-16 weeks old) were purchased from or given by: *OLAC, Bicester, UK; †Jackson Laboratory, Bar Harbor, USA; ‡Tierspital, University of Zurich; §Tierversuchsinstitut Hannover, FRG; ||Institut für biologisch-medizinische Forschung AG, 4414 Füllinsdorf, Switzerland; ¶Bantin-Kingman, Aldbrough, Hull, UK; #Savo-Ivanovas, Kisllegg, FRG. The mice were infected i.c. with 30 µl of LCMV Control mice injected with medium alone did not die.

were injected i.c. with ~500 plaque-forming units (PFU) of docile UBC-LCMV. B10.G(*H-2^q*) and B10.AKM(*H-2^m*) mice died with typical LCM whereas B10.BR, B10.AQR and B10.T(6R) mice survived. As B10.AKM(*D^q*) differs from B10.BR(*D^k*) in the *D* region of *H-2* but has in common *H-2K^k*, *I^k* and the B10 background, susceptibility to LCM is linked to *H-2D^q*. The difference in susceptibility of B10.G or B10.AKM compared with B10.BR was seen over a wide range of docile-LCMV doses between 5×10^4 PFU (the highest dose tested) and ~50 PFU i.c. (results not shown). In contrast, aggressive UBC-LCMV injected i.c. over the same dose range (results not shown, except for 500 PFU, in Fig. 1) caused death in all of the above congenic B10 mice irrespective of their MHC.

As LCMV is a T-cell-mediated immunopathological disease, the question arises of whether greater susceptibility reflects greater LCMV-specific cytotoxic T-cell activity. T-cell-mediated immune reactivity was monitored on days 5, 6 and 7 after i.c. infection with docile UBC-LCMV (Table 2, Fig. 2). We found that inflammatory cells in cerebrospinal fluid (CSF) and meninges of susceptible mice were increased from day 5 onwards, yielding values that were 5-10 times greater than those in resistant B10.BR mice on days 6 and 7. Cytotoxic activity was detectable in meningeal infiltrates and spleens of B10.G or B10.AKM mice on day 5 or 6, earlier than the barely detectable activity of B10.BR mice (day 7). The activities measured were much higher in meningeal or spleen cells from susceptible B10.G or B10.AKM than from resistant B10.BR mice (Fig. 2, Table 2).

Fig. 2 Two to four B10.G(K^q, I^q, D^q) (Δ), B10.AKM(K^k, I^k, D^k) ($\circ$) and B10.BR(K^k, I^k, D^k) ($\bullet$) mice were injected i.c. with ~ 500 PFU of docile UBC-LCMV on days 5, 6, 7 or 8 before they were killed; all B10.G mice and one of two of the B10.AKM mice had died by day 8 ($\dagger$). The target cells used in the cytotoxicity assay were simian virus 40-transformed fibroblast lines (AKM and AK1) or a methylcholanthrene-induced tumour cell line (Q); these cells had been infected with docile UBC-LCMV for 2 days at a multiplicity of infection of ~ 0.01 . The ^{51}Cr -release assay was run for 3.5–5 h in round-bottomed 96-well plates using 10^4 target cells; effector spleen cells were tested at various effector-to-target ratios (50, 17, 6 and 2:1) (only the results for 50:1 are shown). B10.BR spleen cells taken 7 days after immunization i.c. with aggressive UBC-LCMV were also tested on infected AK1 cells ($\star$). Immune B10.G or B10.AKM spleen cells did not induce release of ^{51}Cr from infected AK1 or L929 cells (data not shown). All effector cells were tested against YAC-1 cells, but no release greater than 7% was measured. Spontaneous release was 20–32%. $\dagger$ Indicates that all or some mice had died.

Most of the cytotoxic activity was found to be $H-2D$ -restricted. B10.G effector cells lysed infected K^q, I^q and D^q targets as efficiently as K^k, I^k and D^k targets, and B10.AKM T cells lysed D^q -compatible infected Q($H-2^q$) targets but either did not lyse or only poorly lysed K^k -compatible infected FS-9($H-2^k$) target cells. For example B10.AKM(K^k, D^k) spleens contained $2\text{--}4 \times 10^2$ lytic units (LU) when measured on infected $H-2K^k$, compared with 18 to 55×10^2 on infected D^q targets

(Table 2); this maps most of the $H-2$ -restricted cytotoxic activity to D^q , in agreement with the finding that most LCMV-specific cytotoxic T-cell activity is usually restricted to D (reviewed in ref. 6). Docile UBC-LCMV immune lymphocytes from B10.BR($H-2^k$) mice lysed infected AKM(K^k, D^k) or AK1(K^k, D^k) targets only to a small extent on days 6, 7 or 8. In contrast, those B10.BR mice that were infected with aggressive UBC-LCMV and usually died of LCMV generated high cytotoxic T-cell activity in meninges and spleen when tested on day 7 (Fig. 2, Table 2), most activity being restricted to D^k (Fig. 2)⁶. Therefore, early and high LCMV-specific MHC class I-restricted cytotoxic T-cell activity correlated positively with susceptibility to LCMV and both T-cell activity and susceptibility to LCMV map to $H-2D$. To our knowledge this represents the first model infection in which susceptibility can not only be shown to depend on the virus strain and on the various host genes but also to be directly regulated by classical transplantation antigens.

The clear correlation between early and high cytotoxic T-cell activity in B10.BR mice infected with aggressive as opposed to docile LCMV was not observed by Pfau *et al.* in 3–4 week-old C3H/HeJ mice tested on day 8 on infected L929 target cells¹³; this discrepancy probably represents an exception and might have been caused by the particular conditions used, that is, young age of the host and only one time point tested on L929 target cells. We found a clear correlation in 8–12-week-old C57BL/6, DBA/1, DBA/2, BALB.B and Swiss mice (R.M.Z., unpublished).

The $H-2$ -dependence of susceptibility to LCMV has been studied by Oldstone *et al.*^{14,15}, who found that, on average, SWR/J($H-2^q$) mice died of LCMV to a greater extent with $\sim 10\text{--}100$ -fold smaller i.c. doses of an aggressive, neurotropic LCMV (strain CA1371) than C3H/HeJ ($H-2^k$) mice. This difference in susceptibility was seen during early and shorter (days 6–10) but not longer (days 6–14) observation periods of the disease, since by day 14 there was no longer a significant difference in susceptibility¹⁴. No clear-cut linkage between susceptibility to LCMV and $H-2$ has been shown since^{15,16}.

Murine LCMV represents a laboratory model in which immunocompetent mice die when infected i.c. but do not usually die if infected intravenously (i.v.) with most LCMV strains^{3–6}. The LCMV model thus demonstrates dramatically that T-cell-mediated disease is observed only if a substantial part of crucial cellular compartments, for example, leptomeningeal cells, are infected and damaged^{3–6,17,18}. Preferential infection by LCMV of leptomeninges, as opposed to other tissues or organs, enhances the lethal outcome of LCMV. If frequencies of precursor

Mice were infected with 5×10^2 PFU of aggressive or docile UBC-LCMV. On the days indicated, mice under ether anaesthesia were bled and their cerebrospinal fluid was tapped as described by Carp *et al.*²⁷; about 5 μl CSF was obtained, diluted 1:10 and counted. The skull was opened, the brain removed and both the skull and brain were rinsed with medium in a Petri dish (total cells). Single meningeal infiltrate cells and spleen-cell suspensions were prepared and assayed at ratios of 50, 17, 6 and 2:1 in a 3 $\frac{1}{2}$ -h test on the following ^{51}Cr -labelled docile-infected target cells: FS-9 ($H-2^k$, given by Dr H. Binz), spontaneous release 18%; and Q ($H-2^q$), 21% spontaneous release. Lytic units (LU), the number of cells giving a 33% specific ^{51}Cr -release by B10.BR effector cells on infected $H-2^k$ target cells and by B10.AKM and B10.G on $H-2^q$ target cells. LU of B10.AKM were also determined on infected FS-9 ($H-2^k$) targets. Total spleen cells varied from 5 to 10×10^7 per spleen. The results shown are for one of two similar experiments using two mice per time point. The data represent the mean values for the two mice. NT, not tested.

effector T cells are high, as is probably the case in immunologically high responders (D^q), their protective activity may limit early on the spread of LCMV to sites other than leptomeninges and therefore increase susceptibility to LCM. The differences in susceptibilities to LCM between docile and aggressive LCMV may also reflect $H-2D$ -regulated differences in cytotoxic T-cell responsiveness that correlate with possible but as yet unrecognized antigenic variations between the two substrains. In fact, Ahmed *et al.* have shown that LCMV-specific T-cell clones may distinguish between various LCMV strains that are serologically indistinguishable¹⁹.

Although the linkage of disease to the MHC has long been recognized²⁰⁻²⁵, despite much speculation, it has remained unclear how MHC-restricted T-cell recognition and MHC-encoded *I*_E gene regulation determine the MHC/disease association^{1,6,22,23}.

The observation, reported here, of a correlation between $H-2D$ -regulated T-cell activity and susceptibility to LCM suggests that many such diseases are the result of a T-cell-mediated pathophysiological mechanism⁹. In general, acute infectious agents probably do not cause disease exhibiting MHC/disease associations because such acute agents select evolutionarily for immunologically high responders in most if not all members of a species. Rather, diseases revealing MHC-linked susceptibility are usually chronic diseases of autoimmune^{24,25}, immunopathological^{6,9} or cancerous nature^{20,21}. The linkage of LCM susceptibility to a major transplantation antigen agrees with the notion⁹ that the association of disease susceptibility with the MHC is often found in connection with non- or poorly cytopathogenic infectious agents that may cause chronic infections without interfering with reproduction. These agents leave a certain amount of leeway for a balance between immune protection

and damage caused by the immune response. Accordingly, MHC-associated disease susceptibility may often signal immunological T-cell-mediated pathogenesis.

This work was supported by SNF 3.323-0.82, by USPHSG AI-17285, NS-20913 and the Kanton Zürich.

Note added in proof: Our results are compatible with recent studies by Allan and Doherty²⁶ with BALB/c and $C-H-2^{dm2}$ mutant mice. Mutant mice expressing D^{dm2} were less susceptible to the LCMV-Armstrong isolate than BALB/c mice expressing D^d .

Amplification of P-glycoprotein genes in multidrug-resistant mammalian cell lines

The multidrug-resistance phenotype expressed in mammalian cell lines is complex. Cells selected with a single agent can acquire cross-resistance to a remarkably wide range of compounds which have no obvious structural or functional similarities¹⁻⁶. The basis for cross-resistance seems to be a decreased net cellular accumulation of the drugs involved, and has been attributed to alterations in the plasma membrane. An over-expressed plasma membrane glycoprotein of relative molecular mass (M_r) 170,000 (P-glycoprotein) is consistently found in different multidrug-resistant human and animal cell lines, and in transplantable tumours^{1,2,6-10}. Consequently, it has been postulated that P-glycoprotein directly or indirectly mediates multidrug resistance⁷⁻¹¹. Here we report the cloning of a complementary DNA encoding P-glycoprotein. Southern blot analysis of hamster, mouse and human DNA using this cDNA as a probe showed that P-glycoprotein is conserved and is probably encoded by a gene family, and that members of this putative family are amplified in multidrug-resistant cells.

A cDNA library was constructed using the expression vector λ gt11 (ref. 12) and messenger RNA isolated from the highly multidrug-resistant cell line, CH^RB30 (see accompanying article)⁶. Plaques were selected by probing with a P-glycoprotein-specific monoclonal antibody, C219 (ref. 6). One

of the presumptive P-glycoprotein cDNA clones, containing an insert of ~600 base pairs (bp), was selected for further study. This cDNA, called λ CHP1 when in the λ gt11 vector, or pCHP1 when subcloned into the pUC9 vector¹³, was transcribed into a 140,000- M_r *lacZ* fusion protein in λ CHP1-infected bacterial cells (Fig. 1A). The size of this fusion protein relative to the uninterrupted β -galactosidase suggested that most of the λ CHP1 insert contained P-glycoprotein coding sequence. Strong evidence that the cDNA insert coded for P-glycoprotein sequences is provided in Fig. 1B, where the same *lacZ* fusion protein was recognized by monoclonal antibodies that identify three independent epitopes of P-glycoprotein⁶.

Further corroboration that the cloned cDNA fragment encodes P-glycoprotein was provided by Northern blot analysis of the highly drug-resistant cell line CH^RB30 and of its sensitive parental cell line, AuxB1 (Fig. 2A). The pCHP1 insert hybridized to a single mRNA component of ~4.7 kilobases (kb), which was strongly expressed in CH^RB30. Slot-blots of mRNA isolated from a series of increasingly multidrug-resistant Chinese hamster ovary (CHO) cells, and from a drug-sensitive revertant cell line (Fig. 2B) revealed hybridization signals consistent with the levels expected if pCHP1 sequences encode a portion of P-glycoprotein. Both the correlation of mRNA expression with multidrug resistance and the size of this mRNA species were consistent with that expected for P-glycoprotein².

Southern blot analysis of multidrug-resistant hamster, mouse and human cell lines and of their drug-sensitive parental cell lines (Fig. 3) demonstrated four main points: (1) in all cases, amplification of pCHP1-homologous sequences correlated with expression of multidrug resistance. The degree of amplification increased with increasing drug resistance in the CHO series, and was lost in the CHO revertant, I10. Similar amplification of pCHP1-homologous sequences has also been detected in a daunorubicin-resistant CHO cell line⁷ (data not shown), and in the adriamycin-resistant Chinese hamster lung cell line LZ¹⁴ (J. H. Gerlach and V.L., unpublished observations). Roninson *et al.*¹⁴ have previously observed 55 kilobase pairs (kbp) of amplified DNA fragments common to both LZ and CH^RC5

Fig. 1 β -Galactosidase fusion protein containing a P-glycoprotein-specific cDNA insert. **A**, SDS-polyacrylamide gel electrophoresis (PAGE) of aliquots containing 75 μ g protein from lysates of Y1089 bacteria infected with λ gt11 (*a*) or λ CHP1 (*b*). M_r markers in the extreme left-hand lane were as described previously⁹. Arrows indicate the *lacZ* fusion product of λ CHP1 (top arrow) and uninterrupted β -galactosidase (bottom arrow). **B**, Western blots of lanes shown in **A**. Monoclonal antibodies⁶ recognizing three different epitopes on the P-glycoprotein molecule were used. Three identical blots were probed with representative monoclonal antibodies of group I (C219 probe), group II (C32 probe) and group III (C494 probe), as indicated.

Methods. The cDNA probe, λ CHP1, was obtained as follows. Poly(A)⁺ RNA was isolated from the highly colchicine-resistant cell line, CH^RB30, by standard techniques^{22,23}. cDNA was synthesized and cloned into the β -galactosidase-encoding *lacZ* gene of the bacteriophage λ gt11 (ref. 12) by the methods of Huynh *et al.*²⁴. The library contained 1.3×10^6 recombinants, 65% of which contained cDNA inserts. Screening was done with radioiodinated ($\sim 10 \mu\text{Ci } \mu\text{g}^{-1}$) monoclonal antibody C219. After plaque purification, the insert (~ 600 base pairs, bp) from one of the positive clones, λ CHP1, was subcloned in the plasmid pUC9 (ref. 13). This recombinant, designated pCHP1, was used in subsequent hybridization analyses. Infection of Y1089 bacteria with either λ gt11 or λ CHP1 and induction of the *lacZ* products with isopropyl β -D-thiogalactopyranoside were done as described¹². Bacteria were lysed by brief sonication, solubilized and then subjected to SDS-PAGE according to Laemmli²⁵. Western blot analyses were done according to Towbin *et al.*²⁶, as described previously⁹.

Fig. 2 RNA analysis using the pCHP1 probe. **A**, Northern blots of total cellular RNA from drug-sensitive AuxB1 and highly multidrug-resistant CH^RB30 cells. The third lane contained RNA from normal bovine brain as a control. **B**, Slot-blot analysis of RNA from a series of CHO cells with different levels of drug resistance. The relative resistance to colchicine is indicated opposite each slot^{1,2}. The clonal lines CH^RA3, CH^RB3 and CH^RC5 were derived from sequential selections for increasing colchicine resistance; CH^RB30 was obtained by continuous culture of CH^RC5 in increasing colchicine concentrations from 5 to 30 $\mu\text{g ml}^{-1}$, and revertant I10 was selected from CH^RC5 in a single step^{2,6}. The level of P-glycoprotein expression has been shown to correlate with the degree of drug resistance^{6,9}. Northern and slot blots were performed as described by Thomas²⁷. The probe used was pCHP1 insert, nick-translated to a specific activity of $\sim 10^8$ d.p.m. μg^{-1} .

Fig. 3 DNA analysis with the pCHP1 probe. Southern blots of *Eco*RI-digested genomic DNA from: **A**, the series of increasingly multidrug-resistant CHO cells shown in Fig. 2; and **B**, multidrug-resistant mouse and human cells. Multiple bands were also observed when other restriction enzymes were used with CHO DNA (not shown). Note the appearance of new bands, probably 'novel joints'¹⁵, not detected in sensitive parental cells (for example, band 2 in CH^RC5 and CH^RB30). Quantitative densitometry of the CH^RB30 band pattern in a separate experiment revealed that restriction fragments 4, 6 and 9 were amplified 10–20-fold, while fragments 7, 10, 11 and 12 were amplified 50-fold or more.

Methods. DNA was digested with *Eco*RI and electrophoresed in 0.6% agarose gels. Transfer to nitrocellulose was performed essentially as described by Southern²⁸. Hybridization was in 50% formamide, 5 $\times$ SSC, 20 mM sodium phosphate pH 6.5, 200 $\mu\text{g ml}^{-1}$ sonicated salmon sperm DNA, 0.1% bovine serum albumin (BSA), 0.1% Ficoll, 0.1% polyvinylpyrrolidone, 10% dextran sulphate, plus 10^6 d.p.m. ml^{-1} pCHP1 insert nick-translated to a specific activity of $\sim 10^8$ d.p.m. μg^{-1} . Filters were washed twice for 5 min each in 2 $\times$ SSC, 0.1% SDS at room temperature, twice for 30 min in the same solution plus 0.1% sodium pyrophosphate at 50 $^{\circ}\text{C}$, and twice for 30 min in 0.1 $\times$ SSC, 0.1% SDS and 0.1% sodium pyrophosphate at 50 $^{\circ}\text{C}$. M_r s were determined from *Hind*III-digested λ DNA, which was co-electrophoresed. Hamster cell lines were those described in Fig. 2 legend. The resistant mouse cell line was derived from L cells and was selected with colchicine¹⁰. CEM/VLB₂₅₀₀ is a highly resistant human leukaemic cell line selected for growth in 2,500 ng ml^{-1} vinblastine²⁰, from the resistant subline CEM/VLB₁₀₀ (ref. 4). CCRF-CEM is the drug-sensitive parental cell line. Autoradiographs of hamster DNA were for 15 h, except for the lane marked AuxB1 ($\times 12$), which was exposed 12 times longer. Autoradiographs of mouse and human DNA were for 7 days, except the lane marked ECH^R(10) ($\times 0.1$), which was exposed for one-tenth of that time. Band 1 in AuxB1 is under-represented in this experiment.

using a DNA renaturation technique in agarose gels; in view of our present findings, the P-glycoprotein genes probably comprise a major portion of those sequences.

(2) The pCHP1 insert detected multiple bands in the Southern blots of *Eco*RI-digested DNA, despite the fact that this cDNA fragment was only ~ 600 bp long and contained no internal *Eco*RI sites. Although other explanations are possible, the simplest is that P-glycoprotein is encoded by a multigene family. In support of this notion, only a subset of the 10 bands detected in CHO cells were transfected (and these were amplified) in mouse cells transformed to the multidrug-resistant phenotype with DNA derived from multidrug-resistant hamster cells R.-p. Du, K.D. and V.L., unpublished observations).

Fig. 4 Cytological evidence for localization of amplified P-glycoprotein sequences to a homogeneously staining region (HSR) on the Z4 chromosome of $CH^R B30$. **A**, Representative G-banded $CH^R B30$ cell demonstrating an HSR on chromosome Z4 (arrow). The most consistent and characteristic chromosomal alteration between the parental line AuxB1 and the highly colchicine-resistant $CH^R B30$ line was the presence of an HSR on the long arm of chromosome Z4. **B**, Localization of autoradiographic grains to the Z4 HSR (arrow) following hybridization *in situ* with ^3H -labelled pCHP1. **C**, Examples of grain localization to the Z4 HSR (arrows) from five different $CH^R B30$ cells as in **B**. Of 25 cells examined, 20 yielded one or more autoradiographic grains localized to the Z4 HSR, and 45% (60/133) of all grains were localized to the Z4 HSR. No significant grain localization in the drug-sensitive cell AuxB1 was observed in the same conditions (data not shown). **Methods.** G-banding and *in situ* hybridization analysis were performed as described previously^{29,30}. Cells were hybridized for 15.5 h at a final DNA concentration of $0.65 \mu g ml^{-1}$, followed by exposure for 7 days before autoradiographic development (**B**, **C**). The autoradiographic analysis was performed with unbanded chromosomes; however, the size and arm length ratio of the Z4 HSR allowed it to be unequivocally identified in $CH^R B30$ cells.

(3) The Southern blots also indicate that the presumptive CHO P-glycoprotein gene family appears to be clustered within one amplification unit (an amplicon), because in $CH^R A3$, which was selected in a single step from the sensitive parent AuxB1, all the restriction fragments were simultaneously amplified by ~10–20-fold. Coordinate amplification did not occur in mouse and human cell lines, suggesting that the P-glycoprotein genes detected in these cases were not part of the same amplicon. The appearance of amplified fragments that have no counterparts in parental DNA may represent novel joints. Such regions are found in tandemly amplified sequences¹⁵.

(4) The ability of the pCHP1 insert to detect human sequences under stringent conditions provided evidence that P-glycoprotein is conserved at the DNA level, as well as at the protein level⁶.

Karyotypic markers of gene amplification—homogeneously staining regions or double minute chromosomes—have been described in multidrug-resistant cell lines^{3,11,16–19}. In the CHO cell system, there exists an extensive homogeneously staining region on the Z4 chromosome in $CH^R B30$ cells (Fig. 4) that is not found in the drug-sensitive parental cell line. *In situ* hybridization using ^3H -labelled pCHP1 revealed that the amplified P-glycoprotein sequences reside within the Z4 homogeneously staining region. No significant grain localization to other chromosomes was apparent.

The fact that multidrug resistance is associated with gene amplification suggests that the basis of this phenotype is an increased expression of a normal gene product. It may be speculated that the function of P-glycoprotein in normal cells is to modulate cellular permeability to diverse compounds and that overexpression of P-glycoprotein in multidrug-resistant cells results in an exaggeration of this normal function. The present study raises the possibility that different members of the putative P-glycoprotein gene family control different aspects of permeability, and that the sum of their individual effects produces the diversity of the multidrug-resistance phenotype. Differential expression of members of this family may also result in the variability in resistance patterns among different multidrug-resistant cell lines. The cloning and transfection of a functional P-glycoprotein gene will provide insight into these hypotheses and will determine whether or not overexpression of P-glycoprotein alone is sufficient to mediate the multidrug-resistance phenotype.

Recently, we have detected P-glycoprotein overexpression in some cases of advanced ovarian cancer²⁰. This suggests that the multidrug-resistance mutation can occur in human malignancies and result in non-responsiveness of the malignancy to combination chemotherapy^{6,20,21}. Further studies are required to determine the generality of this finding among other malignancies. The homology of pCHP1 to human P-glycoprotein sequences should facilitate studies in this area.

We thank Drs J. H. Gerlach and D. R. Bell for helpful comments. Part of this work was initiated when one of us (J.R.R.) was on sabbatical leave in the laboratory of Dr George Stark. This work was supported by grants from the MRC of Canada (to J.R.R.), the NCI of Canada (to V.L.), and NCI grant CA-17094 (to J.T.).

Detection of P-glycoprotein in multidrug-resistant cell lines by monoclonal antibodies

Norbert Kartner, Deanna Evernden-Porelle,
Grace Bradley & Victor Ling

One reason for the failure of chemotherapy in the treatment of advanced cancers may be the outgrowth of multidrug-resistant tumour cells¹⁻⁵. Multidrug resistance has been modelled in numerous mammalian cell lines in which the phenotype is characterized by a pleiotropic cross-resistance to unrelated drugs¹⁻⁷. In the study reported here, we have produced monoclonal antibodies whose binding to plasma membranes of different multidrug-resistant mammalian cells correlates with the degree of drug resistance. All these antibodies are specific for P-glycoprotein, a cell surface component of relative molecular mass (M_r) 170,000 (170K) that has been described previously⁸⁻¹⁵, and are directed against three spatially distinct epitopes which define a conserved cytoplasmic domain in the C-terminal region of the P-glycoprotein polypeptide. The conserved nature of P-glycoprotein and its low-level expression in drug-sensitive cells suggest that it has an important function at the cell surface. The monoclonal antibodies against P-glycoprotein described here might serve as diagnostic reagents for clinically unresponsive tumours¹⁶.

Hybridomas were produced from splenocytes of mice immunized with SDS-solubilized plasma membranes of multidrug-resistant Chinese hamster ovary (CHO) and human cell lines. Primary screening of the hybridomas was achieved using nitrocellulose test strips spotted with SDS-solubilized plasma membranes of drug-sensitive and multidrug-resistant CHO and human cells (for details see Fig. 1 legend). By this means we were able to select hybridomas secreting monoclonal antibodies specific for drug resistance-associated antigens in either CHO or human cells. Screening with denatured antigens immobilized on nitrocellulose ensured that the monoclonal antibodies selected would be of use in the detection of antigens in protein immunoblots (Western blots). Eight stable hybridoma clones were ultimately isolated, yielding three monoclonal antibodies which appeared to be specific for resistance-associated CHO antigens, and five that bound antigens common to multidrug-resistant CHO and human plasma membranes.

To characterize the above differences in binding specificity more precisely, supernatants from cloned hybridomas were screened with a larger panel of plasma membranes from drug-sensitive and multidrug-resistant cell lines (Table 1). The results (Fig. 1) showed that the monoclonal antibodies could be classified into three distinct groups according to the pattern of staining obtained in the dot-blot panel. No significant staining of drug-sensitive cell membranes was observed with any of the eight monoclonal antibodies. The antibodies in group I stained membranes of all drug-resistant cells tested, while those of group II failed to stain drug-resistant human membranes. The single member of group III stained drug-resistant CHO and human membranes, but not those of mouse. Further evidence of distinct epitopes was provided by competitive binding assays, as shown in Fig. 2. The latter results clearly allowed the classification of the monoclonal antibodies into three groups (I, II and III) on the basis of their binding to three spatially distinct epitopes.

The antigen specificity of each of the monoclonal antibodies was determined by probing plasma membrane components in Western blots. Figure 3A shows the results for plasma membranes from various cell lines (Table 1). Bands of $M_r \sim 170K$ were stained in lanes representing CHO cells of increasing colchicine resistance (Fig. 3A, lanes b-d), and a daunorubicin-resistant CHO cell line (lane e). Similar results were obtained

Fig. 1 Selection and characterization of monoclonal antibodies, using immunoblotting techniques. Dot immunoblots were used in a primary screening assay to select hybridomas of interest (see below). Shown here are dot immunoblots which were used in a more comprehensive secondary screening of re-cloned hybrids. Eight hybridomas were tested against a panel of SDS-solubilized plasma membranes purified from pairs of matched drug-sensitive (s) and drug-resistant (r) cells; 2 μ l (2 μ g protein) of each were spotted onto nitrocellulose filters. Hybridoma supernatants were adjusted to a monoclonal antibody concentration of 1 μ g ml⁻¹. Note the differential staining of drug-resistant cell membranes. Three different staining patterns were observed and the eight monoclonal antibodies were classified accordingly into groups I, II and III. Comparison of rows 4, 5 and 9 emphasizes major differences in specificity between the groups. The assignment of monoclonal antibodies to groups was as follows. Group I: C11, C26, C36, C219; group II: C32, C103, C699; group III, C494. Their isotypes were κ 2a, except for C11, C26 and C36, which were κ 1. Test cell lines were (sensitive line, resistant line): (1) AuxB1, CH^RB30; (2) AuxE29, DNR^R159; (3) CHEF 18, VCR 1.5; (4) C12TSV₂S, C12TSV₂R₂; (5) LMTK^R, ECH^R; (6) S180, S180A5; (7) UV-2237, UV-2237-ADM^R; (8) LTA, LC5B1; (9) CCRF-CEM, CEM/VLB₅₀₀ (see Table 1 for description of cell lines).

Methods. Twelve-week-old (BALB/c $\times$ 3H)F₁ mice were immunized with injections of purified plasma membranes isolated according to Riordan and Ling¹⁰ from CH^RB30 and CEM/VLB₅₀₀ cell lines. Membrane protein was assayed according to a modification¹² of the method of Lowry *et al.*³³. Membranes were solubilized in a 2% SDS-containing buffer as for SDS-PAGE^{11,12}, with a protein/SDS ratio of 1:1.4, and were emulsified 1:1 with Freund's incomplete adjuvant. The first injection consisted of 200 μ g of CH^RB30 membrane given intraperitoneally, followed after 14 days by a second, identical injection. After 14 months the mice were injected with a mixture of 100 μ g each of CH^RB30 and CEM/VLB₅₀₀ plasma membranes. Identical injections were given 14 and 21 days after the first injection in this series. In addition, on day 21 a mixture containing 100 μ g of sonicated plasma membrane vesicles from each of CH^RB30 and CEM/VLB₅₀₀ was injected intravenously. On day 26, spleens were removed aseptically and splenocytes fused 3:1 with the Sp2/0-Ag14 fusion partner^{34,35}. Cells were plated in 96-well plates at 10⁵ myeloma cells per well in RPMI-1640 medium containing 100 μ M hypoxanthine, 0.5 μ M aminopterin, 30 μ M thymidine, 2 mM L-glutamine, 50 μ M 2-mercaptoethanol and 15% fetal bovine serum. When wells seemed to be 25% confluent (50–80% of wells after 10–14 days), they were screened for specific antibody-producing hybrids. Primary screening of individual hybridoma supernatants was done using a panel of SDS-solubilized plasma membranes, by dot blotting. Test strips were prepared by spotting 1 μ l of SDS-solubilized plasma membrane (1 mg ml⁻¹ protein; prepared as for SDS-PAGE^{11,12}) onto numbered 5 $\times$ 25 mm nitrocellulose strips. Each strip was spotted with plasma membranes from the drug-sensitive CHO cell line AuxB1, the drug-resistant CHO line CH^RB30, the drug-sensitive human cell line CCRF-CEM, and the drug-resistant human line CEM/VLB₅₀₀ (see Table 1 for description of cell lines). The dried dot blots were blocked in 3% bovine serum albumin (BSA)/saline³⁶ for 1 h at 37 $^{\circ}$ C, then placed in test tubes containing hybridoma supernatants diluted 1:10 in BSA/saline. After overnight incubation at 4 $^{\circ}$ C, the strips were washed in several changes of phosphate-buffered saline (PBS), then developed with ¹²⁵I-labelled IgG goat anti-mouse immunoglobulins (Cappel; 10⁶ c.p.m. ml⁻¹ in 3% BSA/saline) for 6 h at 25 $^{\circ}$ C. After washing and drying, the test strips were exposed overnight, with intensifying screens, on Kodak X-AR5 film at -70 $^{\circ}$ C. About 1,000 strips were processed simultaneously. Candidate wells were expanded and cloned twice by limiting dilution. The above screening method was repeated to pick positive clones. Secondary screening, as shown, was done in a similar manner, but using plasma membranes derived from several different cell lines. Eight stable clones were finally isolated.

when blots of colchicine-resistant mouse cells (Fig. 3A, lane h) and vinblastine-resistant human leukaemic cells (lane j) were probed (compare with drug-sensitive parental cells in lanes a, g and i, and a drug-sensitive revertant, lane f). All three classes of monoclonal antibody stained bands of identical M_r when a

side-by-side comparison of Western blots was made (data not shown). Previous work has established that homologous P-glycoproteins with a consistent M_r of 170K are expressed in all the multidrug-resistant cell lines tested here¹¹⁻¹⁵. Longer exposure of the blots (Fig. 3A, lanes k-n) revealed faint bands

in the membranes of drug-sensitive parents and revertant cells in lanes a, f, g and i, respectively. Low-level expression of P-glycoprotein in drug-sensitive cells has been reported previously¹². Trivial explanations for the apparent homologies of the 170K bands in different species, such as detection of pros-

Table 1 Description of cell lines

Cell lines of the series CH^RA3, CH^RB3 and CH^RC5 were clonally selected, stepwise, from AuxB1 (ref. 23). CH^RB30 was selected by continuous culture, in increasing colchicine (CCH) concentrations, from CH^RC5. CP-3.7 is a phytohaemagglutinin (PHA)-resistant mutant, selected from CH^RC5, which retains the multidrug resistance phenotype of CH^RC5 (ref. 14). I10 is a revertant cell line, selected in a single step from CH^RC5 (ref. 25). CEM/VLB₁₀₀ was obtained from Dr W. T. Beck³¹ and was cloned in methylcellulose containing 0.1 $\mu\text{g ml}^{-1}$ vinblastine (VLB). The series of VLB-resistant human leukaemic cell lines, CEM/VLB₅₀₀, CEM/VLB₁₀₀₀ and CEM/VLB₅₀₀₀, was derived from a clone of CEM/VLB₁₀₀ by continuous growth in increasing drug concentrations and selection at 0.5, 1.0 and 5.0 $\mu\text{g ml}^{-1}$ vinblastine, respectively. Relative resistance was determined as described previously²⁴. Relative resistance values for the CH^R CHO series and CEM/VLB series cells were re-assayed for the present work and may not agree exactly with previously reported values. Drugs that were tested for cross-resistance are listed in order of decreasing relative cross-resistance. ACR, acriflavine; ADX, AD-32; AMS, amsacrine; CMD, colcemid; CYB, cytochalasin B; DAC, actinomycin D; DNR, daunorubicin; DOX, adriamycin; EME, emetine; ERY, erythromycin; ETB, ethidium bromide; GRD, gramicidin D; MMC, mitomycin C; MRM, marcellomycin; PRO, proflavine; PUR, puromycin; VCR, vincristine. NA, not assayed.

* Present study.

Fig. 2 Direct competitive binding assay of eight monoclonal antibodies against purified, radioiodinated antibody. Target antigen was plasma membrane vesicles from CH^RB30, immobilized on nitrocellulose in 96-well plates. The abscissa is a logarithmic scale of the ratio of the concentrations of unlabelled competing antibody and radiolabelled antibody. The ordinate shows the percentage of c.p.m. bound, normalized to c.p.m. bound in the absence of competing antibody. Results of single simultaneous experiments are shown for clarity. **A**, Competition between a labelled group I monoclonal antibody (C219) and dilutions of eight different ascites fluids. No group II or III antibodies competed with C219. The shift in the competition curves of other group I antibodies with respect to the self-competition curve of C219 probably reflects differences in binding affinity. **B**, Competition between the group II antibody C32 and other ascites fluids. Monoclonal antibodies of groups I and III did not compete with C32. The binding kinetics of the three group II antibodies appeared to be similar. **C**, Competition data for the single representative of group III (C494). No group I or group II antibodies competed with C494. The monoclonal antibodies tested were: ○, C11; ●, C26; △, C32; ▲, C36; ▽, C103; ▼, C219; □, C494; and ■, C699.

Methods. Millititre HA plates (Millipore) were coated with 1 μg of CH^RB30 plasma membrane in 30 μl PBS per well, and incubated overnight at 37 °C. Wells were blocked with 100 μl of 10% BSA in PBS for 4 h at 37 °C. After washing with PBS, the wells were incubated with 30 μl of radioiodinated, purified monoclonal antibody (20 ng, 100,000 c.p.m.) mixed with 30 μl of ascites fluid serially diluted threefold in 10% BSA/PBS. After incubation for 16 h at 25 °C, the plates were washed with PBS containing 0.1% Tween 20. Dried wells were punched out, and bound ¹²⁵I-labelled antibody was quantitated by γ -counting. Monoclonal antibodies were purified by chromatography on protein A-Sepharose (Pharmacia) and concentrated by ammonium sulphate precipitation³⁷. Purified antibodies were radioiodinated using chloramine T³⁸. C219 protein was quantitated gravimetrically ($\pm 5\%$) by lyophilizing the purified antibody and drying to constant weight, *in vacuo* at 25 °C. Other purified monoclonal antibodies were quantitated by absorbance at 280 nm in PBS against C219 standards. Clarified ascites were titred by spotting twofold serial dilutions onto nitrocellulose and probing with radiolabelled goat anti-mouse immunoglobulins. Spots were compared by autoradiography and densitometry, using purified C219 as a standard. Ascites of Sp2/0-Ag14 cells gave no significant background.

Fig. 3 Specific staining of P-glycoprotein in Western blots and in cells. **A**, Western blots of plasma membranes of drug-sensitive and resistant cells (Table 1), using monoclonal antibody. A group I antibody (C219) was used throughout this figure. Lanes *a*–*d*, CHO cells of increasing drug resistance: *a*, AuxB1; *b*, CH^RB3; *c*, CH^RB3; *d*, CH^RC5; *e*, daunorubicin-resistant CHO cell line, DNR^R51; *f*, drug-sensitive revertant of CH^RC5, I10; note that the staining intensity of the 170K P-glycoprotein band correlates with the degree of drug resistance (Table 1); *g*, sensitive and colchicine-resistant mouse cells (LMTK⁺, ECH^R); *i*, *j*, sensitive and vinblastine-resistant human cells (CCRF-CEM, CEM/VLB₁₀₀); *k*–*n*, eightfold longer exposures of lanes *a*, *f*, *g* and *i*, respectively, showing staining of the 170K band in membranes of drug-sensitive cells; lane *o*, same loading as in *d*, but the blot was treated with bacterial alkaline phosphatase (10 U ml⁻¹ in 10 mM Tris-HCl (pH 8.0), 2 h at 25 °C) according to Davis *et al.*²⁹ before probing with monoclonal antibody. Phosphatase treatment did not affect antibody binding (compare with lane *d*). The same result was obtained when the plasma membrane sample was treated with phosphatase before SDS-PAGE. *p*, CP-3.7, showing that depletion of N-linked carbohydrate¹⁴ on P-glycoprotein (note the shift in *M_r*) did not affect antibody binding. Minor bands of lower *M_r* are probably degradative fragments of the major band. SDS-PAGE according to Fairbanks *et al.*⁴⁰ and Western blots according to Towbin *et al.*³⁶ were performed as described previously^{11,12}, using 50 µg of membrane protein per lane. Protein staining of gels (not shown) gives a complex pattern of at least 30 bands^{11,12}. **B**, Indirect immunofluorescence staining of drug-resistant cells with monoclonal antibody. Mixtures of cell were stained with C219 and fluorescent second antibody: *a*, phase-contrast photomicrograph of a 1:1 mixture of AuxB1 and CH^RB30 cells; *b*, fluorescence photomicrograph of same field as in *a*; *c*, phase-contrast photomicrograph of a 1:1 mixture of CCRF-CEM and CEM/VLB₅₀₀₀ cells; *d*, fluorescence photomicrograph of same field as in *c*. AuxB1 or CCRF-CEM cells alone (not shown) showed no significant fluorescent staining in these conditions. Fields of CH^RB30 or CEM/VLB₅₀₀₀ cells alone (not shown) showed similar staining of all cells. **C**, Flow cytometry of indirect immunofluorescence staining using cell lines of different drug resistance. The abscissa is a logarithmic scale of fluorescence intensity relative to calibration beads (see below). The ordinate shows the relative frequency (*v_r*) of cells in a given fluorescence intensity channel. Typically about 10,000 cells were analysed in 256 channels for each curve. The top panel shows a series of CHO cell lines, the bottom panel a series of human cell lines. Peaks are identified as follows. Top panel: 1, AuxB1; 2, I10; 3, CH^RA3; 4, CH^RB3; 5, CH^RC5; 6, CH^RB30. Bottom panel: 1, CCRF-CEM; 2, CEM/VLB₁₀₀; 3, CEM/VLB₅₀₀; 4, CEM/VLB₅₀₀₀. Staining was done with the monoclonal antibody C219, and fluorescein-conjugated second antibody (see below). Note the correlation between the degree of drug resistance (Table 1) and fluorescence staining intensity. **Methods.** For fluorescence microscopy, cells were fixed in 0.46% formaldehyde in PBS (pH 7.0), on ice for 2–3 min, after which they were washed twice with PBS at 4 °C and fixed further in 95% ethanol at –20 °C for 5 min, then in acetone at –20 °C for 5 min. Cells were pelleted at 4 °C, the acetone was aspirated and the pellet air-dried for 5 min before staining. For flow cytometry, cells were fixed only in 70% methanol at –20 °C for 5 min, and washed twice in PBS before staining. Cells (10⁶ ml⁻¹) were stained in 1% normal rabbit serum (NRS)/PBS containing monoclonal antibody (~3 µg ml⁻¹) from diluted ascites for 1 h at 4 °C with inversion. Cells were washed twice with 1% BSA/PBS, then incubated in fluorescein-conjugated rabbit anti-mouse immunoglobulin (Dako) diluted 50-fold in 1% NRS/PBS for 1 h at 4 °C. Cells were washed three times in 1% BSA/PBS and resuspended in 100 µl of 50% glycerol in PBS containing 20 mg ml⁻¹ 1,4-diazabicyclo(2,2,2)octane. Stained cells were viewed and photographed using a Zeiss epifluorescence microscope fitted with an H485 filter pack. For flow cytometry, cells were resuspended to 10⁶ ml⁻¹ in 1% BSA/PBS and analysed in a Coulter EPICS V flow cytometer. The logarithm of integrated fluorescein isothiocyanate fluorescence was determined with forward-angle light scatter gated to analyse only single cells. Approximately 10⁴ cells were analysed per cell line. Fluorescence intensity was standardized against Coulter 10 µm Full Bright calibration beads at 10-fold and 100-fold attenuation.

thetic groups like phosphate, or common carbohydrate epitopes, are excluded by the controls in Fig. 3A, lanes *o* and *p*: here the absence of phosphate or N-linked carbohydrate moieties, respectively, had no apparent effect on binding of antibody to the antigen. Based on the correlation of increased expression of the antigen with increased multidrug resistance, and the conservation of structure of the antigen irrespective of the drug of selection in a number of mammalian species, we concluded that the antigen bound by each of the monoclonal antibodies was P-glycoprotein, as defined previously¹².

In many diagnostic and research applications, it is important for an antibody to be capable of detecting the antigenic site as it is presented in cells and tissues. In this regard we have found, using both radiolabelled monoclonal antibodies and indirect immunofluorescence staining, that none of the monoclonal antibodies binds the surface of intact multidrug-resistant cells (data not shown). Nevertheless, as shown in Fig. 3B, using fixed and permeabilized cells, the monoclonal antibodies labelled the surface membrane of resistant CHO and human cells, demonstrating their potential as reagents for the diagnostic detection of P-glycoprotein in fixed cells and tissues. In Fig. 3C, flow cytometry of cells stained with the monoclonal antibodies showed that the antibody binding correlated with the degree of

drug resistance of the cells, much like the specific P-glycoprotein staining in Fig. 3A. Thus, the staining of permeabilized cells appeared to be due to specific binding of monoclonal antibodies to epitopes of P-glycoprotein exposed on the cytoplasmic aspect of the plasma membrane.

The group I monoclonal antibody C219 has been used to obtain a 600-base pair (bp) cDNA probe, λ CHP1, from a λ gt11 expression library of the multidrug-resistant CHO cell line, CH^RB30 (see accompanying paper¹⁷). The *lacZ* fusion product of λ CHP1, which expresses a C-terminal fragment of CHO P-glycoprotein, is recognized not only by the monoclonal antibody C219, but by all eight antibodies described here¹⁷. Localization of three independent epitopes to a peptide not more than 200 amino acids long was a surprising result as this represents only ~15% of the P-glycoprotein polypeptide. This observation is consistent, however, with the notion that the monoclonal antibodies detect a cytoplasmic domain in fixed cells, as the C-terminus of a transmembrane glycoprotein is often situated on the cytoplasmic side of the membrane. The observation that the monoclonal antibodies bind a fusion protein produced in bacterial cells further confirms that they are directed against the polypeptide moiety of the P-glycoprotein.

The clustering of all three epitopes in the C-terminus of

P-glycoprotein suggests that this region is relatively more immunogenic than most of the protein. The C-terminus possibly is part of a hydrophilic domain in an otherwise relatively hydrophobic protein. Alternatively, it may be a region of the polypeptide that is conformationally more fluid and, therefore, is more likely to be antigenic¹⁸⁻²⁰. It is significant that all eight monoclonal antibodies showed specificity for the same plasma membrane component, supporting the notion that the expression of P-glycoprotein is the major alteration of the multidrug-resistant cell surface. One of the epitopes described here (identified by group I antibodies) seems to be highly conserved among species, but the other two appear to be expressed in a species-dependent manner, as seen in Fig. 1. The latter epitopes may represent more variable regions of P-glycoprotein structure.

The monoclonal antibodies described here will serve as sensitive and specific reagents for the detection of P-glycoprotein in experimental systems and in normal and neoplastic tissues. Furthermore, they have potential for use in screening human tumour biopsies, where early detection of elevated levels of P-glycoprotein might indicate the need for a departure from routine chemotherapy and the application of novel treatments to circumvent the multidrug resistance phenotype^{7,21,22}. Preliminary findings of elevated amounts of P-glycoprotein in some ovarian carcinomas of patients failing to respond to chemotherapy have already demonstrated the usefulness of the present monoclonal antibodies for this purpose¹⁶.

This work was supported by grants from the NCI of Canada and the MRC of Canada. We thank Drs W. T. Beck, P. G. Debenham, R. Giavazzi, T. Kuo, R. Simard and T. R. Tritton for making available their drug-resistant cell lines; J. F. Harris for helpful discussion; and D. R. Bell and J. H. Gerlach for helpful criticisms.

Bombesin-like peptides can function as autocrine growth factors in human small-cell lung cancer

The autocrine hypothesis proposes that a cell produces and secretes a hormone-like substance that can interact with specific membrane receptors on its surface to induce effects such as proliferation¹. Thus, a cancer cell could act to stimulate its own growth. Bombesin and bombesin-like peptides (BLPs) such as gastrin-releasing peptide (GRP) cause various physiological responses in mammals², including stimulation of proliferation of 3T3 mouse fibroblasts³ and normal human bronchial epithelial cells *in vitro*⁴ and induction of gastrin cell hyperplasia and increased pancreatic DNA content *in vivo* in rats^{5,6}. Human small-cell lung cancer (SCLC) cell lines produce and secrete BLPs⁷⁻¹² and can express a single class of high-affinity receptors for BLPs¹³. Exogenously added BLPs can also stimulate the clonal growth and DNA synthesis of SCLC *in vitro*^{14,15}. These findings suggest that BLPs function as autocrine growth factors for this tumour. One way to test this hypothesis is to interrupt the function of the endogenously produced BLPs. Here, we demonstrate that a monoclonal antibody to bombesin binds to the C-terminal region of BLPs, blocks the binding of the hormone to cellular receptors and inhibits the clonal growth of SCLC *in vitro* and the growth of SCLC xenografts *in vivo*. These results demonstrate that BLPs can function as autocrine growth factors for human SCLC.

The C-terminal region of bombesin and GRP, which competes effectively for the same class of high-affinity receptors on pituitary cells and SCLC membranes, is required for receptor binding and physiological activity^{13,16,17}. Murine monoclonal antibodies were prepared against a synthetic analogue of amphibian bombesin (Lys 3-bombesin) which has the same C-terminal heptapeptide sequence as human and porcine GRP^{18,19}. The neuropeptide substance P has the same carboxy-terminal Leu-Met dipeptide as bombesin but is rarely found in SCLC and binds to a different set of receptors than bombesin^{7,16}. Thus, we screened for monoclonal antibodies that bound to bombesin but not substance P. One anti-bombesin monoclonal antibody, 2A11 (IgG₁ κ), showed no cross-reactivity with substance P and was purified from ascites for study.

Using solid-phase synthetic peptides as targets in a radioimmunoassay (RIA), the 2A11 antibody bound to bombesin, the Lys 3 derivative of bombesin used for immunization, the Tyr 4 derivative of bombesin used for iodination, GRP 1-27, GRP 14-27 and GRP 20-27, whereas GRP 22-27, GRP 1-16, substance P and other tachykinins²⁰ showed insignificant 2A11 binding despite some C-terminal homology with bombesin and GRP (Table 1). In addition, a series of unrelated peptides that can be produced by SCLC, such as calcitonin, adrenocorticotrophic hormone (ACTH), arginine vasopressin (AVP) and neurotensin did not bind 2A11. Note that, although SCLCs make BLPs, the 2A11 antibody did not bind to live, intact SCLC (Table 1).

We next used 2A11 to develop a quantitative, competitive RIA system for BLPs using solid-phase 2A11 and ¹²⁵I-labelled Tyr 4-bombesin. This assay was able to detect BLPs in the range of 5-100 pg per well and BLPs were detected by the RIA in extracts of all 10 SCLC lines tested (Table 2). These values are in good agreement with previously reported quantitative data on many of the same tumour lines using rabbit anti-bombesin heteroantisera⁷. In contrast, none of the non-SCLC lines

Fig. 1 Inhibition of binding of labelled bombesin in a radioreceptor assay by monoclonal antibody 2A11 using rat brain membranes (□)¹⁶ or small-cell lung cancer (NCI-H345) cell (○) preparations¹³. The black symbols on the ordinate show that 67 nM MOPC 21 control immunoglobulin did not inhibit the binding of the labelled peptide to either receptor preparation.

Methods. ¹²⁵I-Tyr 4-bombesin (50–80 μ Ci μ g⁻¹, 40,000 c.p.m. per test) was incubated with the indicated concentrations of purified monoclonal antibody 2A11 for 60 min at 25°. Receptor binding assays were conducted using 10 mg wet weight of crude rat brain homogenate or 2×10^6 cells of SCLC line NCI-H345 as described previously^{16,30}. The difference in binding in the absence and presence of an excess unlabelled bombesin (1 μ M) was taken as a measure of specific binding.

(adenocarcinoma, large-cell and squamous cell lung carcinoma) or the non-lung cell lines (B-lymphoblastoid, T-cell lymphoma and melanoma) expressed detectable levels of BLPs (<0.01 pmol mg⁻¹ acid soluble protein) (Table 2).

As 2A11 bound to the C-terminal region of BLPs (such as GRP 14–27 and GRP 20–27), we tested the ability of the antibody to block the binding of labelled bombesin to its cell-surface receptor on small-cell lung cancer and rat brain membranes (Fig. 1). Antibody 2A11 blocked bombesin–receptor interaction in a dose-related fashion with both receptor preparations (Fig. 1). Almost complete inhibition of bombesin binding (using 12–18 nM labelled bombesin) occurred with 10 nM 2A11. An indifferent mouse myeloma protein, MOPC 21, of the same isotype as 2A11 (IgG₁ κ) at 67 nM did not significantly affect bombesin–receptor interaction ($<1\%$ inhibition).

Antibody 2A11 was then examined for its effect on the *in vitro* growth of SCLC cell lines using an agarose cloning assay. Two types of SCLC cell lines were tested against various concentrations of 2A11. The first was a 'classic' SCLC line (NCI-N592) with typical SCLC morphology (growth in tight balls in suspension, scant cytoplasm) and high specific activities of L-dopa decarboxylase²¹. The second was a 'variant' SCLC line (NCI-N417) that deviates morphologically (growth as loose chains, with large cell cytology and abundant cytoplasm) from typical SCLC, has undetectable levels of L-dopa decarboxylase, grows rapidly, clones with high efficiency and is amplified for the *c-myc* oncogene^{21,22}. Both cell lines produce detectable levels of bombesin (Table 2) and both have the SCLC features of high specific activities of the BB isozyme of creatine kinase and neurone-specific enolase^{21,23}. The clonogenic growth of both cell lines was markedly inhibited by $\geq 3 \mu$ g ml⁻¹ 2A11 (Table 3). In contrast, 10μ g ml⁻¹ of the isotype-matched mouse myeloma protein MOPC 21 or boiled 2A11 showed no significant inhibition of SCLC growth in the same assay (Table 3). Exogenously added synthetic bombesin can stimulate the clonal growth of SCLC in serum-free medium (Table 3)¹⁴. The addition of 50 nM of

Fig. 2 Effect of treatment with monoclonal antibody 2A11 (□), control monoclonal antibody MOPC 21 (Δ) or PBS (○) on growth of human tumour xenografts in athymic nude mice. *a*, Human malignant melanoma cell line NCI-H234A; *b*, human small-cell lung cancer line NCI-N592.

Methods. Tumour cells (10^7 /mouse) were subcutaneously injected into the flanks of athymic nude mice (BALB/c *nu/nu*) and a palpable mass formed after 7 days. Treatment begun on day 7 consisted of three trial groups (5 mice per group), each given 0.5 ml i.p. injections three times a week of either PBS (○), 200 μ g purified MOPC 21 immunoglobulin (Δ) or 200 μ g of purified 2A11 antibody (□). Thus, each mouse in the immunoglobulin-treated groups received a total of 600 μ g immunoglobulin per week for four weeks. Tumours were measured once a week. Tumour growth is reported as an average relative tumour volume, s.e.m. $\pm 10\%$.

Fig. 3 Representative nude mice 5 weeks after xenografting with small-cell lung cancer NCI-N592 and treated with MOPC 21 (mouse 1), PBS (mouse 2) or 2A11 (mouse 3). Arrows point to the site of tumour innoculation. Large tumours are seen for the two controls (1 and 2) and no tumour mass was detected in mouse 3 at week 5.

exogenous synthetic bombesin added simultaneously with 2A11 completely prevented the 2A11 growth inhibition demonstrating the specificity of the 2A11 effect (Table 3).

Nude mouse heterotransplant studies were used to investigate the ability of 2A11 to inhibit SCLC growth *in vivo*. Two tumour cell lines were used in this study, the classic SCLC line NCI-N592 and a melanoma cell line, NCI-H234A, which did not make BLP and which was unresponsive to bombesin *in vitro*¹⁴, to serve as a control. One week after their inoculation into nude

Table 1 Immunological cross-reactivity of solid-phase synthetic peptides with bombesin using the 2A11 binding assay

Peptide target	Cross-reactivity (%)
Bombesin-like peptides	
Bombesin (BN)	100
Lys 3-BN	98
Tyr 4-BN	96
Gastrin-releasing peptide (GRP 1-27)	102
GRP 14-27	102
GRP 20-27	112
GRP 1-16	0.26
GRP 22-27	<0.02
Tachykinins	
Substance P, physalaemin, kassinin, elodeisin	all <0.02
Unrelated peptides	
Calcitonin, vasoactive intestinal peptide, motilin, β -endorphin, leu-enkephalin, glucagon, somatostatin, neurotensin, xenopsin, ACTH, AVP	all <0.07
Bovine serum albumin (BSA)	<0.02
Live small-cell lung cancer cells	<0.02

BALB/c mice were immunized subcutaneously three times with Lys 3-bombesin conjugated to BSA²⁴ (100 μ g bombesin equivalents per injection; the first dose was in complete Freund's adjuvant, the last two in incomplete Freund's). Monoclonal antibodies were derived by standard methods following fusion to the mouse myeloma cell line X63-Ag8.653 (refs 25, 26). Hybrids were screened for anti-bombesin activity 10 days after fusion by indirect RIA using radio-autography on solid-phase target plates coated with bombesin, substance P or 1% BSA. Hybridomas producing antibodies binding to bombesin but not BSA or substance P were cloned several times. Monoclonal antibody 2A11 (IgG₁ κ) was grown in ascites, purified²⁷ and used for all subsequent tests. For solid-phase RIA, peptides (all purchased from Peninsula Laboratories) were adsorbed to 96-well polyvinyl chloride microtitre plates (Dynatech) by adding 0.05 ml 10 μ g ml⁻¹ peptide in PBS for 1 h, washing in PBS, then blocking with a 1% BSA/PBS solution. Porcine sequence synthetic GRP peptides were used¹⁸. Viable SCLC cell lines NCI-H128, NCI-H209 and NCI-H345 at 10⁵ cells per well were tested in binding assays using 96-well plates with glass filters (V & P Scientific, San Diego)²⁸. Purified 2A11 (10 μ g ml⁻¹) was added, incubated and washed three times. Protein A affinity purified rabbit anti-mouse IgG (Cappel Laboratories) (1.6 μ g ml⁻¹) was added, incubated, washed three times, then ¹²⁵I-protein A (Pharmacia, labelled by chloramine T method to 40–50 μ Ci μ g⁻¹) 40,000 c.p.m. per well was added, incubated, washed eight times and the wells cut out and counted in a Beckman γ -counter. All incubations were for 1 h at room temperature in PBS with 1% BSA in 0.025 ml volumes. Percentage cross-reactivity = (c.p.m. ¹²⁵I-protein A bound on peptide target – c.p.m. bound on BSA target)/(c.p.m. bound by bombesin – BSA background $\times$ 100). The bombesin target caused 2A11 binding sufficient to bind 33,000 c.p.m. of ¹²⁵I-protein A whereas the BSA background bound 30 c.p.m. Mouse myeloma protein MOPC 21 (IgG₁ κ , Litton Bionetics) was used as a control at 10 μ g ml⁻¹ and did not bind to the peptides. All values are the average of triplicate determination and variation between replicates was <5%.

mice each cell line produced a palpable tumour mass. The established tumours were then subjected to three experimental treatments (five mice each group) consisting of: (1) phosphate-buffered saline (PBS); (2) the isotype-matched immunoglobulin MOPC 21; and (3) 2A11. Treatment was administered by intraperitoneal (i.p.) injection three times weekly and tumour growth was monitored as a function of tumour volume over the next four weeks of therapy (Fig. 2). The melanoma cell line, NCI-H234A, showed unhampered tumour growth in all three experimental groups with each group of mice attaining an average tumour volume of 1,000 mm³ by week 5 (Fig. 2a). In contrast, dramatic suppression of SCLC growth (NCI-N592) was observed following 2A11 treatment (tumour mass in all mice <50 mm³) while control groups of MOPC 21- and PBS-treated mice demonstrated rapid tumour growth (tumour mass in all mice >1,000 mm³ by five weeks) (Figs 2b; 3). Note that in MOPC 21-treated controls there was an unexplained tem-

Cell lines were grown as described previously^{21,23} and for preparation of cell extracts for RIA, 1–5 $\times$ 10⁷ cells were washed three times in PBS and resuspended in 1 ml of 2 M acetic acid, homogenized, heated in a boiling water bath for 15 min, clarified by centrifugation at 3,000 r.p.m. and the supernatant lyophilized and stored at –80°. The freeze-dried extract was resuspended in 0.5–1 ml PBS, reclarified and protein concentration determined using a BioRad assay kit. Dilutions of this extract were tested in a quantitative competitive RIA. Antibody 2A11 was adsorbed to 96-well polyvinylchloride plates at 500 ng per well followed by saturation with 1% BSA-PBS. Unlabelled bombesin (covering a range of 1–1,000 pg per well bombesin for a standard curve) or cell extract peptides at different dilutions were added to triplicate wells and incubated for 1 h at 25 °C. Without removing the unlabelled peptides, 12,000 c.p.m. of ¹²⁵I-Tyr 4-bombesin (labelled by the chloramine-T method to 50–80 μ Ci μ g⁻¹) was added to each well and incubated overnight at 4 °C, washed eight times and counted. All additions were in 1% BSA-PBS in 0.025-ml volume, and the washes were with 1% BSA-PBS. GRP 1-27, GRP 14-27 and GRP 20-27 were equipotent with bombesin in competing for labelled bombesin and the midpoint of the assay curve detected 25 pg bombesin per well. In contrast, substance P, unrelated peptides and synthetic analogues of bombesin or GRP with substitutions blocking binding to the cellular BLP receptor were unable to significantly compete with labelled bombesin in this assay. In addition, MOPC 21 immunoglobulin did not bind the labelled peptide. Using the standard curve, the BLP equivalent of the cell extract peptides was determined and expressed as pmol of BLP mg⁻¹ of acid soluble protein in the extract. Results are the average of triplicate determinations with variation between replicates of <5%.

porary delay in tumour growth in some mice, but in all cases a large tumour had formed by five weeks.

In the 2A11-treated group, three more weeks of treatment were given; two mice never showed tumour growth, but three developed progressively growing NCI-N592 tumours despite 2A11 treatment. These antibody-resistant tumours are under study. At week 5, the 5 mice with large NCI-N592 tumours in the PBS-treated group were then treated with 2A11 antibody for three weeks and the tumours in all 5 mice stopped growing and became necrotic.

In conclusion, we have reported on a monoclonal antibody to amphibian bombesin that cross-reacts with BLPs of human origin. The antigenic determinant for this antibody has been localized at the C-terminal region of bombesin and GRP. We have demonstrated that 2A11 can be used in an RIA for the quantitative detection of BLPs in extracts of human SCLC. The antibody was shown to block bombesin-receptor interaction in

Table 3 The effect of monoclonal antibody 2A11 on the *in vitro* clonal growth of human small-cell lung cancer lines

Addition to cloning medium	Cell line	
	NCI-N592	NCI-N417
Growth as % control (no of colonies)		
Experiment 1 ($\mu\text{g ml}^{-1}$)		
None	100 (30)	100 (583)
2A11 0.1	93 (28)	98 (571)
2A11 1.0	83 (25)	96 (560)
2A11 3.0	0 (0)	3 (18)
2A11 10	0 (0)	1 (7)
MOPC 21 10	97 (29)	99 (577)
Experiment 2		
None	100 (32)	100 (610)
50 nM bombesin	>100 (664)	>100 (820)
2A11 10 $\mu\text{g ml}^{-1}$	0 (0)	5 (30)
MOPC 21 10 $\mu\text{g ml}^{-1}$	94 (30)	100 (607)
Boiled 2A11 10 $\mu\text{g ml}^{-1}$	88 (28)	97 (593)
2A11 10 $\mu\text{g ml}^{-1}$ + bombesin 50 nM	>100 (340)	>100 (910)

Tumour cell cloning assays were performed in serum-free HITES medium as described previously²⁹. HITES medium contains RPMI-1640 (GIBCO) supplemented with 10 nM hydrocortisone, 5 $\mu\text{g ml}^{-1}$ bovine insulin, 10 $\mu\text{g ml}^{-1}$ human transferrin, 10 nM 17 β -estradiol and 30 nM selenium. A single-cell suspension of NCI-N592 or NCI-N417 cells taken from log-phase cultures was mixed with 0.3% agarose in HITES (v/v) in the absence or presence of purified 2A11 or MOPC 21 antibody, bombesin, boiled antibody or 2A11 + bombesin (added simultaneously) and plated over a pre-hardened base layer of 0.5% agarose/HITES. The NCI-N417 culture plates were supplemented with 0.1% BSA which greatly enhanced clonal cell growth. NCI-N592 cells were seeded at 5×10^4 per plate, whereas NCI-N417 cells were plated at 1×10^4 . Plates were pre-screened to verify single-cell distribution of test cells and scored 21 days later for colony formation. Cell aggregates of >50 cells were scored positive for colony growth. All studies were done in triplicate and each point represents the mean colony count. For all studies the s.e.m. was $\pm 10\%$.

both brain and SCLC membrane preparations. Finally, purified antibody when added to an *in vitro* tumour cloning assay or to an *in vivo* nude mouse xenograft assay prevented tumour cell growth. The antibody effect *in vitro* was blocked by synthetic bombesin, and the antibody did not inhibit the growth of a melanoma tumour cell line that did not make BLPs. We conclude that BLPs can indeed function as autocrine growth factor(s) for human SCLC. It is possible that the bombesin stimulation of growth seen in SCLC could reflect a physiological role of BLPs in some cells during normal fetal growth and development. In addition, our studies with monoclonal antibody 2A11 against BLP offer a new immuno-hormonal approach of manipulating the growth of human SCLC in patients. Although these studies used monoclonal anti-peptide antibodies to inhibit BLP action, it is possible that growth suppressive effects could be obtained using bombesin antagonists or anti-receptor antibodies.

We thank H. Sims, A. Simmons and S. Stephenson for technical assistance and Drs A. Gazdar, J. Battey, E. Sausville and M. Kuehl for discussions.

Recent studies have demonstrated that the cellular tumour antigen p53 (ref. 1) can complement activated *ras* genes in the transformation of rat fibroblasts, suggesting that the gene encoding p53 may act as an oncogene^{2,3}. Here, by using *in situ* chromosomal hybridization^{4,5}, we have mapped the p53 gene to human chromosome 17, at bands 17q21-q22, the region containing one of the breakpoints in the translocation t(15;17) (q22;q21) associated with acute promyelocytic leukaemia (APL)^{6,7}. Hybridization of p53 and *erb-A* (17q11-q12) probes to malignant cells from three APL patients indicated that the p53 gene is translocated to chromosome 15 (15q+), whereas *erb-A* remains on chromosome 17. Analysis of variant translocations demonstrates that the 15q+ chromosome contains the conserved junction⁸, suggesting a role for p53 in the pathogenesis of APL. However, rearrangements of the p53 gene were not detected on Southern blotting of DNA from leukaemic cells of four APL patients with t(15;17).

To determine the chromosomal localization of the p53 gene, we performed *in situ* chromosomal hybridization using a p53-specific probe. We used an ³H-labelled complementary DNA clone, pp53-176, containing the entire coding region (1.35 kilobases, kb) of the murine p53 gene⁹, for *in situ* hybridization to normal human metaphase chromosomes prepared from phytohaemagglutinin-stimulated peripheral blood lymphocytes. Figure 1 shows the distribution of labelled sites in 100 metaphase cells examined. This hybridization resulted in labelling of a specific region of a single chromosome, namely, the long arm of chromosome 17. Of 100 metaphase cells examined, 24 (24%) were labelled on region q2, bands q21-q25, of one or both chromosomes 17. A total of 183 grains was observed; thus, the labelled sites on region q2 of chromosome 17 represented 14.2% of all labelled sites (26/183). The largest number of grains was clustered at 17q21-q22 (18/183, 10%, $P < 0.005$).

The localization of the p53 gene to 17q21-q22 is of particular interest because of the nonrandom abnormalities involving this

Table 1 *In situ* hybridization of a p53 probe to metaphase cells with a t(15;17)

Patient	No. of metaphase cells analysed	Total no. of labelled sites	No. of labelled sites (%)			
			Normal 15	15 q+	Normal 17	17 q-
1	100	141	5 (3.5%)	14 (9.9%)*	10 (7.1%)†	2 (1.4%)
2	50	73	1 (1.4%)	7 (9.6%)*	7 (9.6%)*	0 (—)
3	63	84	2 (2.4%)	7 (8.3%)†	10 (12%)*	1 (1.2%)

* χ^2 values correspond to $P < 0.05$.† χ^2 values correspond to $P < 0.20$; however, all grains were clustered on the translocated material from chromosome 17, at bands q21-q22.

chromosome in human tumours. Gain or loss of a whole chromosome 17 has been a frequent finding in haematological malignant diseases as well as in various solid tumours, and structural rearrangements involving 17q are especially frequent in the leukaemias¹⁰. In particular, a reciprocal translocation involving chromosomes 15 and 17 at bands q22 and q21, respectively, is a characteristic abnormality in APL. We have observed this translocation in each of 42 patients with APL that we studied in our laboratory (ref. 7 and our unpublished data).

With regard to the t(15;17), the proto-oncogene *erb-A* has also been mapped to the long arm of chromosome 17. Analysis of hybridizations of an *erb-A*-specific probe to metaphase cells with a t(15;17)¹¹, and Southern blot analysis of somatic cell hybrids retaining the 15q+ chromosome¹², showed that *erb-A* remains on the rearranged chromosome 17. Moreover, no rearrangements of this gene were detected on digestion with eight restriction enzymes of genomic DNAs from five APL patients¹³.

To determine whether the p53 gene or *erb-A* is localized near the chromosomal breakpoint on chromosome 17 that is involved in the t(15;17), we hybridized the two probes to metaphase cells from three APL patients who had this rearrangement. Figure 2 shows the distribution of labelled sites, using each probe, on the rearranged chromosomes and on the normal homologues in cells from patient no. 1. Of 100 metaphase cells examined after hybridization with the p53 probe, 10 (10%) were labelled on the normal chromosome 17; these sites were clustered at 17q21-q22, and represented 7.1% (10/141) of all labelled sites ($P < 0.05$). Two labelled sites were observed on the 17q- chromosome. In 14 metaphase cells, labelled sites were observed on the 15q+ chromosome; they were clustered at bands q21-q22 of the translocated chromosome 17 (14/141, 9.9%, $P < 0.05$). The chromosome 15 homologue had only five labelled sites dispersed along the long arm (3.5%, $P > 0.05$). Thus, the p53 gene, which is normally localized at 17q21-q22, is translocated to chromosome 15 as a result of the t(15;17). Analysis of cells from the two other patients with this rearrangement gave similar results (Table 1).

In contrast, an analysis of metaphase cells hybridized to *erb-A* revealed that this gene remains on the 17q- chromosome and thus is located proximal to the t(15;17) breakpoint (Fig. 2). In 100 metaphase cells examined from patient no. 1, 11 and 10 labelled sites were observed on the normal chromosome 17 and on the 17q- chromosome, respectively (normal 17: 11/125, 8.8%; 17q-: 10/125, 8.0%, $P < 0.05$). In each case, the grains were clustered at 17q11-q12. Two labelled sites were noted on the normal chromosome 15 homologue (1.6%), and four were observed on the 15q+ chromosome (3.2%, $P > 0.05$). Similar results were obtained for hybridizations of metaphase cells from the two other APL patients. This result is consistent with the findings of previous studies in which both *in situ* chromosomal hybridization and Southern blot analysis of DNA from somatic cell hybrids retaining the 15q+ chromosome, were used^{11,12}. Recent results of *in situ* hybridizations to metaphase chromosomes derived from a fibroblast cell line with a different translocation, t(15;17)(q22;q11), suggest that *erb-A* is localized between bands 17q11 and q21 (ref. 13). Our results indicate that the breakpoint on chromosome 17 in the t(15;17) in APL is bracketed by the *erb-A* and p53 genes.

To determine whether the p53 gene is structurally altered by this translocation, we subjected DNA from four APL patients with the t(15;17) to Southern blot analysis using the mouse p53 cDNA probe; human placental DNA served as a germline control. It was necessary to reduce the stringency for these hybridizations, as there is only ~80% homology between the mouse and human genes¹⁴. DNA of high relative molecular mass was prepared and digested with the appropriate restriction enzyme, electrophoresed in 0.8% agarose, and blotted onto Gene Screen Plus transfer membranes (NEN). The blots were hybridized with the plasmid pp53-176, which had been nick-translated with ³²P to a specific activity of 3×10^8 d.p.m. μg^{-1} . Hybridization was for 16 h at 37 °C in 50% formamide, $5 \times \text{SSC}$ ($1 \times \text{SSC} = 0.15 \text{ M}$ sodium chloride, 0.015 M trisodium citrate), 10% dextran sulphate, 1% SDS, 20 mM sodium phosphate (pH 6.8), 0.1% Ficoll, 0.1% polyvinylpyrrolidone, 0.1% bovine serum albumin, and denatured salmon sperm DNA at $100 \mu\text{g ml}^{-1}$. After hybridization, the filters were washed in $3 \times \text{SSC}$, 0.1% SDS for 3 h at 55 °C, followed by 30–120 min at 68 °C, as needed, to reduce the background. In all four patients, we observed the following germline bands: *Eco*RI, 18 kb; *Pst*I, 2.9 and 1.6 kb; and *Pvu*II, 4.0 kb. This pattern is consistent with previously published results, except that the 1.6-kb band expected with *Pvu*II¹⁴ was not observed consistently, suggesting that hybridization of this region to the murine probe was weaker than to the human probe. Thus, there were no detectable changes in the structure of the p53 gene in these samples.

Recent studies with the human APL cell line HL60 have demonstrated that most of the p53 gene has been deleted from these cells, except for a small amount of residual 5' sequences¹⁵. From our *in situ* chromosomal hybridizations and Southern analyses, it is clear that there are no major deletions in the p53 gene in fresh APL cells. Our inability to detect new restriction fragments of the p53 gene on Southern blots, however, does not

Fig. 1 Distribution of labelled sites in 100 normal metaphase cells. From a total of 29 grains on chromosome 17, 18 (62%) were localized at 17q21-q22. Human metaphase cells prepared from phytohaemagglutinin-stimulated peripheral blood lymphocytes were hybridized with ³H-labelled pp53-176 plasmid DNA nick-translated with all four ³H-labelled deoxynucleotide triphosphates to a specific activity of 2.8×10^7 d.p.m. μg^{-1} . *In situ* hybridization was performed as described previously⁵.

Fig. 2 Distribution of labelled sites on normal chromosome homologues 15 and 17, and on the translocation derivatives 15q+ and 17q-, in metaphase cells from an APL patient (no. 1) with a t(15;17), which were hybridized to the p53 or *erb-A* probes. One hundred metaphase cells were examined for each probe. Arrows identify the breakpoint junctions on the rearranged homologues. The results of these hybridizations indicated that the p53 gene is translocated to chromosome 15, whereas *erb-A* remains on chromosome 17. The radiolabelled probes were nick-translated to specific activities of 2.9×10^7 (p53) and 4.9×10^7 d.p.m. μg^{-1} (*erb-A*). The *erb-A*-specific probe (c-HerbA-1) was a 1.6-kb human *erb-A* cDNA clone¹¹.

exclude the possibility that the gene is activated by the translocation, as a rearrangement may have occurred outside the regions homologous to the probe (protein-coding region). Such a situation has been reported for the *c-abl* proto-oncogene in the t(9;22) associated with chronic myelogenous leukaemia¹⁶. Similarly, in Burkitt's lymphoma, rearrangements are usually seen within the introns of the protein-coding regions of *c-myc* in the common t(8;14); however, such rearrangements occur outside this region in the variant translocations t(2;8) and t(8;22)^{17,18}. Thus, in the latter translocations, rearrangements of *c-myc* cannot be detected with a probe containing only protein-coding sequences.

The location of two genes (the p53 gene and *erb-A*), each with transforming capabilities, adjacent to the t(15;17) breakpoint raises the question as to which gene is involved in the pathogenesis of APL. In a reciprocal translocation such as t(15;17) there are two rearranged junctions, and there is no *a priori* reason for choosing either the 15q+ or the 17q- chromosome as containing the critical junction. The analysis of complex translocations that involve three chromosomes can reveal which of the junctions that are seen in the simple translocation is conserved. Such an analysis has been performed for t(15;17) as well as t(8;14) and t(9;22)⁸; in the latter two translocations, the 14q+ and 22q- (Philadelphia, Ph¹) chromosomes contained the conserved junctions. Subsequent molecular analysis has shown that each of these chromosomes contains the critical genes [*c-myc* and immunoglobulin heavy chain on 14q+ (refs 17, 18), and *c-abl* and *ber* (breakpoint cluster region) on Ph¹ (refs 16, 19)]. For t(15;17), the 15q+ chromosome junction was conserved in three clearcut complex translocations^{20,21}. In two other reports of variant translocations, however, either the karyotypes permit several interpretations²² or they have not been published²³.

Thus, most of the data available support the notion that the 15q+ chromosome contains the critical junction, and this would suggest that the p53 gene has a critical involvement in the transformation of normal myeloid cells into leukaemic cells whose maturation is arrested at the promyelocyte stage. Further investigation of the role of the p53 gene in t(15;17) awaits

molecular cloning of the junction fragment and analysis of the p53 gene product in these malignant cells.

We thank Carlo M. Croce for the gift of the *erb-A* probe, Rafael Espinosa and Alanna Harden for technical assistance, and Debbie Gifford and Grace Kim for help in preparing the manuscript. This work was supported in part by the US Department of Energy, contract DE-ACO2-80EV10360; USPHS grant CA16910 from the NCI; and by the University of Chicago Cancer Research Foundation (to J.D.R.). M.M.LeB. is a Fellow of the Leukemia Society of America. C.A.W. is a Fellow of the Damon Runyon-Walter Winchell Cancer Foundation. M.O. is a Scholar of the Leukemia Society of America.

Note added in proof: We have recently confirmed the localization of p53 to 17q12-q24 by hybridizing a human p53 cDNA probe to normal metaphase cells. In addition, a smaller yet significant cluster of grains was observed on 17p11-p13; this labelling was not seen with the mouse probe.

Unusual organization and diversity of T-cell receptor α -chain genes

Adrian C. Hayday*, Don J. Diamond, Gary Tanigawa, Joseph S. Heilig, Virginia Folsom, Haruo Saito & Susumu Tonegawa

Center for Cancer Research and Department of Biology, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA

T lymphocytes recognize cell-bound antigens in the molecular context of the self major histocompatibility complex (MHC) gene products through the surface T-cell receptor(s). The minimal component of the T-cell receptor is a heterodimer composed of α and β subunits, each of relative molecular mass (M_r) $\sim 45,000$ (refs 1-3). Recently, complementary DNA clones encoding these subunits have been isolated and characterized along with that of a third subunit of unknown function, termed γ (refs 4-9). These studies revealed a primary structure for each subunit that was clearly similar to that of immunoglobulin and indicated a somatic rearrangement of corresponding genes that are also immunoglobulin-like. Recently, the analysis of the sequence organization of the T-cell receptor β -chain¹⁰⁻¹⁶ and T-cell-specific γ -chain gene families¹⁷ has been reported. We now present an initial characterization of the murine T-cell receptor α -chain gene family, and conclude that although it is clearly related to the gene families encoding immunoglobulins¹⁸, T-cell receptor β -chains¹⁰⁻¹⁶ and also T-cell γ -chains¹⁷, it shows unique characteristics. There is only a single constant (C) region gene segment,

* Present address: Department of Biology, Yale University, New Haven, Connecticut 06511, USA.

which is an exceptionally large distance (~20–40 kilobases (kb) in the cases studied here) from joining (*J*) gene segments. In addition, the *J* cluster and the variable (*V*) segment number seem to be very large. Finally, in the case studied here, a complete α -chain gene shows no somatic mutation and can be assembled directly from V_α , J_α and C_α segments without inclusion of diversity (D_α) segments.

We reported previously⁶ the isolation of a cDNA (pHDS58) from a cloned cytotoxic T lymphocyte (2C) that encodes the T-cell receptor α -chain¹⁸. The sequence of this cDNA clone showed that, by analogy with immunoglobulin genes, the cDNA can be divided into *V*, *J* and *C* regions⁶. The whole α -cDNA, or its fragments containing one or more regions, was used to probe *Eco*RI-digested BALB/c embryo DNA. The results can be summarized as follows (Fig. 1). First, there are at least four fragments (20, 15, 9 and 2.2 kb) carrying V_{2C} or V_{2C} -like sequences, indicating that the pHDS58 *V* region is derived from a family of closely homologous germline *V* DNA segments. Second, the 2C *V* probe hybridized most intensely with the 2.2-kb fragment, suggesting that this fragment contains the germline counterpart of the pHDS58 *V* region. Third, the pHDS58 *J* region is encoded in an *Eco*RI fragment of ~800 base pairs (bp). Fourth, *Eco*RI fragments of 6.2 and 3.9 kb contain the genetic information for the 3' and 5' ends of the *C* region, respectively, suggesting that, unlike the β - and γ -genes, the BALB/c embryo contains only one *C* gene segment for the α -chain. In addition, when we analysed BALB/c embryo DNA using *V*-region probes derived from several other α -chain cDNAs, we detected different hybridization patterns composed of multiple bands (data not shown), suggesting that, unlike the β -chain gene family, the α -chain gene family contains many germline V_α DNA segments.

The 2.2-kb *Eco*RI fragment containing the germline counterpart of the pHDS58 V_α region was cloned (clone λ 2.2) and sequenced. The sequence is identical to that derived from the corresponding region of pHDS58, indicating that somatic mutation did not occur in the formation of the complete α gene (Fig. 2a). The same conclusion has been reached for a β -chain¹² and for T-cell γ genes¹⁷.

DNA clones containing the various genomic DNA sequences of the J_α - C_α region in the germline configuration are summarized in Fig. 3a (see legend for details of the derivation of these genomic clones). All genomic clones isolated with phage λ vectors are from BALB/c and the cosmid clone 11E is from C57BL/6. However, the Southern blot analysis (Fig. 3b) indicates that there is no gross length polymorphism between these two strains in the relevant region.

We determined the exon-intron structure of the C_α sequence by DNA sequencing (Fig. 2c). Apart from the overall homology with the *C*-gene segments of immunoglobulins, T-cell receptor, β -chain and T-cell-specific γ genes, a striking feature of the α -chain *C* region is its shortness. This is primarily reflected in the first exon which encodes a *C* domain of only 87 amino acids. By contrast, the analogous exons of the T-cell receptor β -chain genes and of the immunoglobulin heavy-chain genes and T-cell γ genes are, respectively, 124 (ref. 10) and 110 amino acids^{17,19}. The second *C*-segment exon is similar to that of the T-cell receptor β -chain and T-cell γ -gene *C* segments in encoding only a short, cysteine-containing peptide of similar size, but not homologous in sequence, to the exon that encodes the hinge region of IgG²⁰. The third exon primarily encodes the putative transmembrane domain and the proposed cytoplasmic tail, and the fourth exon encodes only 3' untranslated region. Terminal exons that encode only untranslated region are a feature of some class II MHC genes²¹, but are without precedent among immunoglobulin, T-cell receptor β -chain^{10,11} and T-cell γ genes¹⁷.

The *J*-segment sequence (Fig. 2b) derived from clone λ *9.1 (Fig. 3) clearly represents the *J* segment used to assemble the α -chain gene (pHDS58) active in 2C cells. It demonstrates two features that are highly conserved among *J* segments: the nucleotide sequence GGNNNGGN that encodes 'G-G',

Fig. 1 *Eco*RI-cleaved BALB/c embryo DNA electrophoresed through 0.9% agarose gels, transferred to nitrocellulose (BA85)²², and hybridized to probes derived from cDNA pHDS58 as indicated in the diagram. Probes were labelled by nick translation²³, and the sizes (kb) of the fragments detected are indicated. All samples, except those probed with probe 380, were run on the same gel, which was subsequently divided into strips. The arrow indicates a fragment of ~800 bp, which is detectable with *J* probe (no. 99) and faintly with other *J*-containing probes. Fragment sizes were determined from co-electrophoresis of phage λ DNA cut with *Hind*III and *Sall*.

which is invariant in functional *J* segments outside the γ -gene family, and the presence 5' to the *J*-coding region of the conserved nonamer and heptamer sequences implicated in *V*-*J* rearrangement (Fig. 4)²². The sequences, separated by 12 bp, are essentially complementary to a heptamer and nonamer that occur immediately 3' to the V_α segment separated by 23 bp (Figs 2a, 4). The spacings of 23 bp in the sequences 3' to V_α and of 12 bp in the sequences 5' to J_α are common among the three T-cell-specific rearranging genes, α , β and γ , and suggest (according to an empirical rule^{23,24}) that these *V* segments can join directly to the respective *J* segments without the involvement of the third (*D*) segment (see below).

By the criteria of the conserved 'G-G' coding triplets and the conserved heptamer and nonamer sequences, we searched for additional *J* segments and found a second (J_1) *J* segment >700 bp downstream of the first one, and a third one (J_2) ~0.5 kb downstream of the second (Figs 2b, 3a). A fourth, J_{C10} used by the α -chain of a helper T-cell hybridoma, was mapped by Southern blotting to ~4.0 kb downstream of J_2 . Three more *J* segments (J_{C11} , J_{B8C3} and J_{DFL12}) were mapped on another genomic clone, λ 8.2, whose DNA occupies a region upstream of the C_α gene segments (Fig. 3a). Thus, we have mapped seven different J_α segments over a distance of ~20 kb. More *J* segments may exist in the 19-kb region between J_{DFL} and C_α , and possibly also 5' to J_{2C} . By comparison, the two T-cell receptor J_β clusters are spread over 1.1 and 1.9 kb (refs 10, 12), the immunoglobulin J_H cluster over 1.36 kb (refs 23, 25) and the immunoglobulin J_K cluster over 1.4 kb (refs 22, 26). In each of these cases the *J* segments are relatively evenly spaced ~50–500 bp apart. Given that the first seven J_α segments we have identified were all different and that our analysis already points to clustering of some J_α segments (J_{2C} , J_1 and J_2 ; and J_{C11} , J_{B8C3} and J_{DFL}), the α -gene family must contain many more J_α segments. If there are 20 J_α segments, the probability that the first seven analysed would be different is significant (30%). Our analysis of *J* segments shows those used by cytotoxic T lymphocytes and by T-helper cells to be interspersed one with another, as with T-cell receptor β -chain segments^{10,12}, implying

Fig. 2 Comparison of T-cell receptor α -chain sequences and cDNA α -sequences. *a*, Comparison of germline V sequence (gV_{α}) determined using clone λ 2.2 as described in ref. 34 and cDNA pHDS58 sequence⁶ throughout the V segment. The perfect homology of the two sequences is indicated (for the protein coding regions only) by dashes, but extended upstream of that for all the available pHDS58 sequence⁶. A candidate transcriptional start site is superscripted with an arrow, being within a sequence (underlined) resembling Py---PyAPyPyPyPy³⁵. Between 20 and 30 bp upstream of this is a candidate TATA box (underlined)³⁵. The exon *V.I* denotes the putative leader region although the transcript of this region is contiguous with that of upstream untranslated sequence. The splice donors and receptors are overlined with dots. The proposed heptamer and nonamer V segment signal sequences at the 3' end of V are indicated. *b*, Comparison of germ line J_{α} sequence (gJ_{α}) and pHDS58 sequence through the J segment. The J_{α} segment completes the α -chain V region, that is, exon *V.II*. 3' of this is shown sequence of another putative J_{α} segment (J_1) from downstream in the germline. *c*, Comparison of germline C_{α} sequence (gC_{α}) and pHDS58 sequence throughout the C segment. Homology is shown by dashes only for the protein coding sequences. Exon *C.IV* encodes only untranslated RNA. The germline sequence of this continues for over 500 bp with the same sequence as was determined for pHDS58 (data not shown).

Fig. 3 The murine embryonic *J-C* region. *a*, The map was deduced by analysis of the recombinant clones indicated. Clones $\lambda 3.9$ and $\lambda 6.2$ were derived from a library of six-fractionated BALB/c embryo *EcoRI* fragments using probes 380 and 343 (see Fig. 1), respectively. Clone $\lambda 8.2$ derived from the same library using a *J* probe from a cDNA α derived from T_H hybridoma B8C3 (L. Glimcher and P. Allen, manuscript in preparation). Clones $\lambda *1.2$, $\lambda *5.1$ were derived from a Charon 4A library of partially *EcoRI**-digested BALB/c embryonic DNA using the 800-bp *EcoRI/BamHI* fragment EB from $\lambda 3.9$ as the hybridization probe. Clone $\lambda *15.2$ and $\lambda *9.1$ were derived from the same library using probe 99 (Fig. 1). Cosmid 11E was derived from a partial *Sau3A* library of C57.B6 embryo DNA. The maps of the clones, assignment of coding sequences and overlap between clones were determined by restriction analysis, cross-hybridization and DNA sequence, and were confirmed by genomic Southern analyses of embryonic DNA of BALB/c and of C57.B6 mice. As an example, the probe KX, stretching from a *KpnI* site in the L arm of Ch4A to an *XbaI* site in clone $\lambda *5.1$, detects in the murine germ line a *BamHI* fragment of 10.2 kb and an *XbaI* fragment of 3.8 kb, consistent with the mapping shown here. Furthermore, the *BamHI/EcoRI* fragment of $\lambda 8.2$ in turn hybridized to KX, as well as to the 400-bp fragment that lies between the left-most *EcoRI* site in the insert of $\lambda *5.1$, and the L-arm. Restriction sites are: E (*EcoRI*), B (*BamHI*), X (*XbaI*), K (*KpnI*), SL (*SalI*) and St (*Sst*). Maps are not necessarily complete, notably for *EcoRI* and *XbaI* on cosmid 11E. In addition to B8C3, J_α segments were localized for T_H hybridomas C10 and C11 (Glimcher and Allen, in preparation), and for cytotoxic T-lymphocyte clone DFL.12 (ref. 36). Exons are boxed and shaded if translated. Germline $V_{2C\alpha}$, cloned in $\lambda V2.2$, lies upstream at an as yet undetermined distance from J_{2C} . *b*, Southern analysis of BALB/c and C57.B6 genomic DNA using cosmid 11E-derived probes. Embryonic DNA from BALB/c and C57.B6 mice was co-electrophoresed on 1.2% agarose gels after restriction with *Sst* (St) or *KpnI* (K) and *SalI* (SL). Southern transfers of the electrophoresed DNA were probed with either the 1.2-kb *SalI* fragment (dotted line in *a*) for St-cut DNA or the 0.6-kb St-E fragment (dotted line in *a*) in the case of SL-K-cut DNA. Methods are further described in Fig. 1 legend.

Fig. 4 Comparison of germline $V_\alpha(gV_\alpha)$, germline $J_\alpha(gJ_\alpha)$ and cDNA pHDS58 sequences indicates recombination of V_α to J_α at point R. The germline gJ has homology at its 5' end to sequences of $\delta B1-1$ and $\delta B2-1$ (refs 13, 14). The proposed heptamer and nonamer sequences 3' to V and 5' to J, respectively, are underlined.

that there is no functional clustering of *J* segments in either gene family.

One consequence of the large *J* cluster is the presence of an unusually long intron between *V-(D)-J* and *C* segments in at least some assembled α genes. For example, in the 2C α gene this intron is ~40 kb, which is without precedent among immunoglobulin or immunoglobulin-like genes characterized to date. Very large introns have recently been discovered in the *Ubx* and *Antp* loci of *Drosophila melanogaster*²⁷; in *Drosophila*, the large intron may be differentially processed, whereas here the primary function of the large intron may be to accommodate many *J* segments. Because of the similarity between both the gene segments that comprise T-cell receptor and immunoglobulin genes and the overall organization of these gene families, transcriptional activity at the promoter of a rearranged V_α gene segment may be enhanced in an analogous manner to that of rearranged immunoglobulin V_H and V_K segments. However, if a tissue-specific enhancer (analogous to the immunoglobulin enhancer) does exist in the *J-C* intron of the T-cell receptor α -chain genes, it must be activating the promoter

associated with the rearranged V_α gene segment at a distance of at least 20 kb in 2C cells. Alternatively, the existence of such a large J_α cluster may have excluded the activation of V_α segment transcription by this mechanism.

One interesting feature of the J_{2C} segment is its unusual length of 63 bp (Fig. 2b)^{10,12,25}. At its 5' end, the *J* sequence GCAGACAGGGC resembles the sequences of the T-cell receptor β -chain gene *D* segment^{13,14} (Fig. 4). Thus, the J_{2C} segment can be regarded as a *D*-type element of 11 bp pre-fused in the germ line to a *J*-type element of 52 bp. In both IgH and T-cell receptor β -gene families, single *D* elements occur in relatively close proximity to the respective *J* clusters^{13,14,28}. It is possible that the analogous D_α segment does not exist, having already fused to J_α to generate the J_{2C} segment in the germ line. The implication is that, albeit at low frequency, cells other than lymphocytes can effect *D-J* recombination.

Another interesting feature of the J_{2C} segment is its direct joining with the germline V_{2C} segment in 2C cells. The fusion of the germline V_{2C} and J_{2C} segments should create a novel V_α probe reactive *EcoRI* fragment of 1.9 kb in 2C cells (probe 371)

Fig. 5 *a*, *EcoRI*-cleaved DNA of BALB/c embryo, E and cytotoxic T-lymphocyte clone 2C cells, electrophoresed through 0.9% agarose, and analysed as described in Fig. 1. *b*, *EcoRI*-cleaved and *HindIII*-cleaved DNA of BALB/c embryo, E and 2C cells, analysed as described in Fig. 1 and hybridized with probe 343 (see Fig. 1). Bands strongly detected in 2C DNA but not in embryo DNA are arrowed.

that would not be present either in germline DNA, B-cell DNA or DNA of T cells that have not made this particular *V-J* combination. Such a fragment is detected in 2C DNA (Fig. 5a). In IgH, T-cell receptor β -chain or T-cell γ -gene families, extra nucleotides are commonly found between the fused *V* and *J* segments¹⁸. These insertions are either template-independent or the result of the participation of a third type of germline DNA segment, *D*, in the fusion process^{13,14,28,29}. Although the 12/23-bp spacer rule permits direct *V-J* joining for the T-cell β -receptor and T-cell γ -gene families, no such case has yet been clearly demonstrated. By contrast, the germline *V_{2C}* and *J_{2C}* sequences presented here can fully account for the sequence of pHDS58 in the *J* region (Fig. 4), strongly suggesting that a direct *V-J* joining has taken place. However, α -cDNA sequences derived from other cytotoxic T-lymphocyte clones and helper T-cell hybridomas (unpublished data) as well as the sequences of other germline *J_α* segments strongly suggest that complete α genes are also assembled with the participation of *D* segments.

Probe 343 (Fig. 1) derives solely from the 3' end of *C_α*, and detects in BALB/c embryo DNA a single *EcoRI* fragment of 6.2 kb and a single *HindIII* fragment of ~7 kb. Surprisingly, when this probe is directed against *EcoRI*- or *HindIII*-cleaved 2C cell DNA, it detects additional fragments (Fig. 5b) which, because of their reproducibility, are apparently not caused by partial digestion of 2C cell DNA. The nature of the gene rearrangement in 2C cells relative to the BALB/c germ line that generates these novel fragments is unclear. Candidates include chromosomal rearrangements 3' to the *C_α* locus, or amplification of germline sequences which, when in single copy, are undetectable with probe 343. Note that in the experiments shown in Fig. 5b, an excess of digested BALB/c embryo DNA was loaded in an effort to detect in the germline single-copy, unrearranged versions of the novel bands present in 2C cells.

In conclusion, our characterization of murine gene segments encoding the T-cell receptor α -chain indicates a multi-gene family that is comprised of many *V*-gene segments, a large array of *J*-gene segments and a single *C_α* gene. Furthermore, our data strongly suggest that a given pair of *V_α* and *J_α* segments can join either directly, without the participation of a *D_α* segment, or indirectly, through one or more *D_α* segment(s). Thus, the scope for combinatorial diversity of the α -gene family seems to be significantly greater than that of IgH, IgK and T-cell receptor β - and γ -gene families. By contrast, the data presented here for the 2C α gene and those reported earlier by others for β genes¹²

and by us for γ genes¹⁷ did not give any indication of somatic mutation, an important source of diversity for immunoglobulin genes¹⁸. This apparent lack of somatic mutation in T-cell receptor genes may be related to the relatively large combinatorial diversity seen in the α -gene family, the latter partially compensating for the former. However, apparent somatic mutation of both α - and β -chain T-cell receptor genes was noted on *in vitro* passage and subcloning of an interleukin-2-secreting T-cell hybridoma³⁰. The role of somatic mutation in diversifying the T-cell receptor repertoire³¹ remains an open question.

We thank Howard Siegel for technical assistance and Eleanor Basel for preparation of the manuscript. We also thank Drs D. M. Kranz, H. N. Eisen, L. Glimcher and W. Häas for T-cell clones and hybridomas. D.D. is a fellow of the Leukemia Society; J.S.H. is supported by an NIH predoctoral training grant 2T32CA09255; V.F. is supported by a fellowship from the Cancer Research Institute. The work was supported by AI-17879, CA-28900 (S.T.) and CA14051 (a core grant to S. Luria). **Note added in proof:** After submission of this manuscript, we learned that two other groups have also found an unusually large number of germline *J* DNA segments^{37,38}.

Genomic organization of the genes encoding mouse T-cell receptor α -chain

Astar Winoto, Shelley Mjolsness & Leroy Hood

Division of Biology, California Institute of Technology, Pasadena, California 91125, USA

The vertebrate immune system uses two kinds of antigen-specific receptors, the immunoglobulin molecules of B cells and the antigen receptors of T cells. T-cell receptors are formed by a combination of two different polypeptide chains, α and β (refs 1-3). Three related gene families are expressed in T cells, those encoding the T-cell receptor, α and β , and a third, γ (refs 4-6), whose function is unknown. Each of these polypeptide chains can be divided into variable (*V*) and constant (*C*) regions. The *V_β* regions are encoded by *V_β*, diversity (*D_β*) and joining (*J_β*) gene segments that rearrange

Fig. 1 Restriction map of the mouse cosmid cluster containing the J_α gene segments and the C_α gene. Open boxes indicate restriction fragments that hybridize to the 500-bp *Sau3A* fragment C_α probe from A10 cDNA clone or to the synthetic oligonucleotide J_α probes. Solid boxes indicate the J_α gene segments that have been sequenced in this paper. Unassigned sites between two restriction sites are indicated by +. The J_α gene segments lie to the 5' side of the C_α gene whose direction of transcription is to the right. The J_α gene segments are named according to the cDNA clone from which they originated^{15,16,18}. The cDNA library was constructed in λ gt10 vector as described³⁸, with minor modification. The second-strand synthesis was done using RNase H, DNA polymerase I and T4 ligase³⁹ and the unincorporated nucleotides were removed at every step by NH_4 -acetate/ethanol precipitation. The cosmid library was constructed and screened as described previously⁴⁰. The oligonucleotides for J_α gene segments were purified in a 20% preparative polyacrylamide gel. The DNA band was visualized by placing a silica gel 60F-254 precoated TLC plate (EM reagents) under the gel and shining short ultraviolet light from above. The DNA band was then cut out, crushed and mixed with 3 ml 0.5 M NH_4 -acetate, 10 mM Mg-acetate, 1 mM EDTA, 0.1% SDS and elution was at 37 °C for 3 h with shaking. The acrylamide was then separated from the DNA by spinning in a Quick-sep Isolab column and the aqueous solution containing oligonucleotide was concentrated to <0.2 ml by several *sec*-butanol extractions. Desalting of DNA was done in a 5 ml Sephadex G25 column. Fractions were collected and monitored by a spectrophotometer. The pure oligonucleotides were kinased as described previously⁴¹. Hybridization of the J_α oligonucleotides was done in 6×SSC, 5×Denhardt's, 0.1% SDS and 100 $\mu\text{g ml}^{-1}$ denatured salmon sperm DNA at 37 °C with 5×10^5 c.p.m. ml^{-1} . The blots for oligonucleotides were washed at 25 °C in 6×SSC, 0.1% SDS.

in the differentiating T cell to generate V_β genes⁷⁻¹⁴. The V_γ regions are encoded by V_γ , J_γ and, possibly, D_γ gene segments^{4,5}. Studies of α complementary DNA clones suggest that α -polypeptides have V_α and C_α regions and are encoded by V_α and J_α gene segments and a C_α gene¹⁵⁻¹⁷. Elsewhere in this issue we demonstrate that 18 of 19 J_α sequences examined are distinct¹⁸, indicating that the J_α gene segment repertoire is much larger than those of the immunoglobulin (4-5) or β (14) gene families. Here we report the germline structures of one V_α and six J_α mouse gene segments and demonstrate that the structures of the V_α and J_α gene segments and the α -recognition sequences for DNA rearrangement are similar to those of their immunoglobulin and β -chain counterparts. We also show that the J_α gene-segment organization is strikingly different from that of the other immunoglobulin and rearranging T-cell gene families. Eighteen J_α gene segments map over 60 kilobases (kb) of DNA 5' to the C_α gene.

A full-length cDNA probe, A10, was obtained for the isolation of germline V_α , J_α and C_α clones from a λ gt10 cDNA library of the T-cell helper hybridoma 1.9.2 using an oligonucleotide probe specific for the C_α gene^{15,16}. DNA sequence analysis showed that the A10 clone was identical in sequence to the published full-length cDNA clone TT11 derived from a T-cell hybridoma¹⁵. A V_α -specific probe was derived from the A10 cDNA and used in Southern blot analysis to demonstrate a V_α rearrangement in the BW5147 tumour DNA (data not shown). As both α -sequences come from different T-cell hybridomas which have the BW5147 cell line as a common parent, these observations suggest that clone A10 is derived from the T-cell tumour BW5147 α -gene. This V_α -specific probe was then used to isolate both germline and rearranged clones of the BW5147 V_α subfamily from a λ genomic library of the 1.9.2 hybridoma DNA.

A C_α -specific probe was obtained from the A10 cDNA clone and used in Southern blot analysis of several mouse DNA clones digested with various restriction enzymes. These data indicate that there is only one cross-hybridizing C_α gene (data not shown). The C_α -specific probe was then used to screen a cosmid library constructed from liver DNA of the inbred B10.D2-H-2^{dml} mouse to obtain three overlapping cosmid clones (Fig. 1). Two successive chromosomal walks were then performed with single-copy probes isolated from the 5' ends of cosmid clones TA4.1 and TA52.1 to yield five additional clones (Fig. 1). These eight

cosmid clones encompassed 119 kb of DNA and contained all 18 J_α gene segments described elsewhere in this issue¹⁸.

To study the structure of the V_α gene segment, we isolated a germline V_α clone, V_α 5H, using the V_α -specific probe from the A10 cDNA. The V_α 5H has a leader exon of 49 nucleotides separated by an intron of 188 nucleotides from a V exon of 287 nucleotides (Fig. 2a). The leader coding segment is split by an intron probably four codons from its 3' end. The V_α 5H sequence seems to represent a functional V_α gene segment and belongs to the V_α 1 subfamily which contains at least 10 different members (ref. 18 and A.W., unpublished data). The V_α 5H coding region is 96% homologous at the DNA level and 98% homologous at the protein level to the coding region of the A10 cDNA clone, hence these sequences represent closely related members of the V_α 1 subfamily (see ref. 18).

The 3' end of the V_α gene segment is marked by a recognition sequence for DNA rearrangement¹⁹. It consists of a conserved heptamer sequence CACAGTG, a 21-base pair (bp) spacer sequence and an A+T-rich nonamer sequence (Fig. 2). The recognition signal is very similar to those of the κ and heavy (H) immunoglobulin¹⁹ and β and γ T-cell gene families^{5,7,8,10,11}.

The C_α gene is 79 kb from the 5' end of the cosmid cluster and 37 kb from the 3' end (Fig. 1 and A.W., unpublished data). The locations of J_α gene segments were determined using 18 oligonucleotide probes that were synthesized corresponding to the 5' or 3' ends of the J_α cDNA sequences^{15,16,18}. As the 5' and 3' ends of the J_α coding regions are different from one another¹⁸, the oligonucleotide probes do not cross-hybridize in the conditions used. In each case only one restriction enzyme fragment from the cosmid clones hybridized to each of the individual oligonucleotide probes. Eighteen J_α gene segments map over a region which extends from 3 to 63 kb 5' to the C_α gene (Fig. 1). The precision in the assignment of the J_α gene segment locations varies within 0.5 to 4 kb of DNA because of the limited number of restriction enzymes that we have used to map the cosmid clones. Hence, the distribution of J_α gene segments is strikingly different from the distribution of the J gene segments of immunoglobulin and the T-cell β - and γ -genes. The J_α gene segments are spread over at least 60 kb of DNA, whereas the J_β and J_γ gene clusters extend over only 2 kb of DNA. Assuming that the 18 J_α gene segments analysed are a random representation of the J_α gene segment repertoire, the fact that all of them

Fig. 2 a, DNA sequence of the germline and the rearranged V_{α} gene segments; **b**, alignment of germline and rearranged sequences of the V - J junction. **a**, The leader and variable coding regions of the germline V_{α} 5H and rearranged A10 cDNA clone are indicated. See text for a discussion of 5' and 3' boundaries of the V gene segment. Boxes in the coding region indicate codons with replacement changes and boxes in the 3' end of the V_{α} gene segment indicate the recognition sequence for DNA recombination. The A10 cDNA clone was obtained from the 1.9.2 helper T-cell cDNA library using an oligonucleotide specific for the C_{α} region^{15,16}. The clone was subcloned in M13mp18 and sequenced by the dideoxy chain termination method as described elsewhere^{20,42}. The λ genomic library from the 1.9.2 helper T-cell hybridoma was constructed in EMBL3 vector as described^{41,43}. The library was screened using a 300-bp *Rsa*I/*Eco*RI V_{α} -specific probe from A10 cDNA. The V_{α} -containing fragment from the V_{α} 5H λ clone was subcloned into M13mp18 or mp19 and sequenced as described^{20,42}. **b**, Upper line represents the TT11 cDNA sequence and the lower the germline J_{α} sequence. Above and below the nucleotide sequences are the translated protein sequences. V and J regions are indicated. Dots between the V and J region indicate extra nucleotides between them; dots below the nucleotide sequences indicate identity to the DNA sequence given above; a dash indicates identity to the protein sequence shown above. Only the 3' part of the V_{α} region of the cDNA is shown.

map to the available cosmid clones is consistent with the hypothesis that most of the J_{α} gene segments will map to the 63-kb region of DNA 5' of the C_{α} gene. As only one of 19 J_{α} sequences analysed in the accompanying paper¹⁸ was a repeat, the repertoire of J_{α} sequences is probably larger than 18.

Six germline J_{α} gene segments were subcloned into M13 bacteriophage and sequenced using specific oligonucleotide primers²⁰ (Fig. 3). The coding regions of the J_{α} sequences were identified by a sequence encoding Phe-Gly-X-Gly that is conserved in virtually all T-cell J gene segments. The 5' boundary of the J_{α} gene segments was determined by the presence of a one-turn recognition sequence for DNA rearrangement. The 3' boundary was determined by analyses of the germline and cDNA sequences¹⁸ in this region which permitted identification of the site for RNA splicing between the J_{α} and C_{α} sequences.

These are several unique features of the germline J_{α} segments. First, they are longer than the J gene segments of immunoglobulin and β -genes by 3–9 codons. Second, the J_{α} gene segments exhibit length heterogeneity at their 3' ends; this heterogeneity is in contrast to the other J gene segments within a particular family (λ , κ , H, β), which all have the same lengths at their 3' ends. All the immunoglobulin and T-cell J gene segments exhibit length heterogeneity at their 5' ends. Thus, the J_{α} sequences are more heterogeneous than their immunoglobulin and β counterparts¹⁸.

The recognition sequences for DNA rearrangement that lie 5' of each of the J_{α} gene segments are very similar to those found in the immunoglobulin and β -gene families (Fig. 3). They each have a highly conserved heptamer separated from an A+T-rich nonamer by a 12-bp spacer sequence. In addition, the 3' splicing site for joining the J_{α} to the C_{α} RNA sequences contains the canonical RNA splicing donor sequence GTAAG²¹.

The fact that the V_{α} gene segments have recognition sequences with 23-bp spacers (two DNA helix turns) and the J_{α} gene segments have recognition sequences with 12-bp spacers (one turn) establishes that all three rearranging gene families in T cells (α , β and γ) use similar kinds of recognition sequences for their V and J gene segments. In the case of the β -genes,

the D_{β} gene segments have a one-turn recognition sequence to the 5' end and a two-turn recognition sequence to the 3' end and accordingly join one- to two-turn recognition sequences in the process of rearrangement and juxtaposition of the V_{β} , D_{β} and J_{β} gene segments⁹. The question of whether or not D_{α} gene segments exist remains. However, even without D_{α} gene segments, a V_{α} may join to the J_{α} gene segment because of the complementary one- and two-turn recognition sequences.

The J_{α} gene segments are more widely spaced from one another than are their immunoglobulin and β -gene counterparts. The immunoglobulin and J_{β} gene segments within a cluster are separated by 36–519 nucleotides, with most of the J gene segments separated by <350 bp. We have sequenced 500 and 400 bp to the 5' and 3' side of the J_{α} 19 gene segment, 400 and 500 bp to the 5' and 3' sides of J_{α} 80, 400 bp to the 5' side of J_{α} 65 and 200 bp on both sides of the J_{α} TT11 gene segment. In addition, we have sequenced more than 900 bp 5' to the J_{α} pHDS 58 gene segment (Fig. 3 and A.W., unpublished data); in each case, we failed to observe an adjacent J_{α} coding region as defined by the invariant Phe-Gly-X-Gly sequence.

A comparison of homologous sequences from the J_{α} gene segments isolated from DNA of the B10.D2.H-2^{dml} mouse and the cDNA clones derived from AKR and BALB/c mice^{15,16} shows that these J_{α} sequences have several nucleotide differences as well as a one-codon sequence gap. Because each J_{α} oligonucleotide probe hybridizes to just a single germline sequence, these observations suggest that J_{α} gene segments are polymorphic. Analysis of V_{α} gene segments also reveals that there are many polymorphisms in the V_{α} gene segments¹⁸. The polymorphism that is present in the α -gene family is significantly greater than that seen in the β -gene family²².

The presence of a D_{α} gene segment in a rearranged V_{α} gene should lead to additional nucleotide sequence between the germline V_{α} and J_{α} gene-segment sequences. The alignment of the A10 cDNA clones and the available germline V_{α} and J_{α} gene segments demonstrates that there are two extra nucleotides between the V_{α} and J_{α} gene segments in this clone (Fig. 2b). The J_{α} gene segment is the germline equivalent to that expressed

Fig. 3 DNA sequence of six germline J_α gene segments. The J gene segments are translated into protein sequence with the one-letter code. The J_α designations are given above the protein sequence. Recognition sequences for recombination are boxed and the RNA donor splicing sites are underlined. Cosmid restriction fragments containing the J_α gene segments were purified using low-melting point agarose and then subcloned into M13 bacteriophage mp18 or mp19 or both⁴⁴. Plaques of M13 containing the J_α sequences in both orientations were identified by hybridization to the J_α oligonucleotides made from DNA sequences of both strands. The following cosmid fragments were used for subcloning: 0.5-kb *Hind*III fragment for J_α TT11, 1.8-kb *Kpn*I fragment for J_α pHDS 58, 2-kb *Xba*I fragment for J_α 80, 1-kb *Bam*HI/*Hind*III fragment for J_α 84, 2-kb *Bam*HI fragment for J_α 19 and 0.5-kb *Xba*I fragment for J_α 65. DNA sequencing by the dideoxy chain termination method was done essentially as described previously⁴² and modified²⁰. Some of the DNA sequencing was done by the chemical degradation method⁴⁵. DNA sequencing was done for both strands. For every J_α -containing fragment >0.5 kb, two complementary 17-mer J_α oligonucleotides were used for the first strand sequence analysis. The opposite strands of DNA were sequenced by two additional oligonucleotides (17-mer) made according to the information obtained in the first strand DNA sequencing. Hence, at least four different oligonucleotides were made and used for sequencing one J_α gene segment to obtain information on both strands. In one case in which we could not obtain clones containing opposite orientations of the J_α gene segment (J_α TT11), the sequence was confirmed by the Maxam-Gilbert sequencing method⁴⁵.

in the A10 cDNA, whereas the germline V_α gene segment belongs to the same V_α subfamily but is not identical. In the V_α , V_H and V_β gene families, members of the same V subfamily always end at the same codon position relative to the conserved second cysteine codon. The additional nucleotides between the rearranged V_α and J_α sequences may be explained in three ways. First, the extra nucleotides can arise from D_α gene segments that are joined to the V_α and J_α gene segments. Second, these extra sequences could arise as a result of N -region diversification. This mechanism results in the addition of random nucleotides to the 5' and/or 3' sides of the D gene segments during the joining process²³. In the immunoglobulin light-chain gene families, which do not have D gene segments, N -region diversity does not occur. Third, it is possible that the extra nucleotides are actually part of the V_α gene segment. These three possibilities cannot yet be distinguished. However, either D_α gene segments exist, N -region diversification occurs in a rearranging gene family lacking D gene segments, or the V_α gene segments within a subfamily differ in the lengths of their 3' ends.

The immunoglobulin and β -gene families use various mechanisms for somatic diversification. Junction variability occurs as a consequence of the flexibility in sites at which the gene segments are joined; and somatic hypermutation, the apparently random mutation of up to 3% of the bases in and

around a rearranged V gene, occurs in immunoglobulin genes, but rarely in β -genes^{24,25}.

The α -gene family also uses various mechanisms for somatic diversification. An alignment of the germline V_α and J_α gene segments with their cDNA counterparts revealed that there is flexibility in the sites at which the gene segments are joined together. For example, in the TA19 cDNA¹⁸, the J_α gene segment is joined five bases into the coding sequence. Thus, diversity can be introduced in the junctional region by a mechanism similar to those seen in the immunoglobulin and β -gene families. The data are inadequate to draw firm conclusions about somatic hypermutation in V_α genes because, apart from the A10 clone, these cDNA clones were derived from a thymic cDNA library. In B cells somatic hypermutation occurs late in B-cell development²⁶ and T cells in the thymus are at early stages of development. Two sets of α -gene segments do not exhibit somatic mutation. First, a comparison of the four germline J_α gene sequences analysed here with their cDNA counterparts from the same inbred strain reveals that there is no somatic mutation (see Fig. 3 and ref. 18). Second, three cDNA clones with identical V_α gene segments have been identified in the 19 different cDNA clones studied and all are found to be identical¹⁸.

The immunoglobulin and T-cell β - and γ -gene families have four distinct types of J -C organization (Fig. 4). (1) The immunoglobulin κ -genes have a cluster of four functional J

Fig. 4 Schematic diagram of the gene organization for the immunoglobulin and T-cell receptor gene families. Distances between *J* and *C* gene segments for immunoglobulin^{27,28,31,46} and T-cell rearranging^{5,7,10,11} families are indicated. Boxes indicate the *V* gene segments or the *C* genes, vertical lines the *D* or the *J* gene segments.

gene segments located 2.5 kb to the 5' side of a single *C_κ* gene^{27,28}; (2) the H-chain genes have four *J_H* gene segments lying 6.5 kb 5' to the *C_H* gene, the most 5' of eight different *C_H* genes^{29,30}; (3) the λ family has four single *J* gene segments, each lying 1.2–1.3 kb 5' of separate *C* genes³¹. Similarly, the γ-gene family has three single *J* gene segments, each lying 3.8 kb 5' of separate *C* genes⁵; (4) the β gene-family has two clusters of *J* gene segments, each with six functional members. These clusters are located ~2.5 kb to the 5' side of the two *C_β* gene segments^{7,10,11}. In each case, when multiple *J* gene segments exist, they are closely clustered, separated by 36–519 bp, with most of the *J* gene segments separated by <350 bp (Fig. 4). We have demonstrated here that the 18 *J_α* sequences map across 60 kb of DNA. As 18 out of 19 *J_α* gene segments analysed are different, many additional *J_α* gene segments will probably be found in this region. This is in striking contrast to the other five rearranging immunoglobulin families where the *J* gene segments are relatively close to the *C* gene (Fig. 4).

The disperse organization of the *J_α* gene segments has several consequences. (1) The size of nuclear transcripts for immunoglobulin and T-cell receptor genes is determined by the length of the *J*–*C* intron. In the immunoglobulin, β- and γ-gene families, these introns vary between 1.2 and 8 kilobases. In contrast, the homologous introns of the α-gene vary between 3 and >63 kb. Thus, the α-transcripts must vary from 6 to >66 kb. Several other eukaryotic genes have larger nuclear transcripts^{32–34}. (2) The large distance between the rearranged *V_α* gene and the *C_α* gene may have interesting regulatory implications. In immunoglobulin H-chain and κ light-chain genes, enhancer sequences are found in the intron between the 3'-most *J* and the *C* sequences^{35–37}. If similar enhancer sequences exist in the α-gene family, the enhancer sequence could be ≥60 kb from the promoter on which it presumably operates. This possibility raises interesting questions about the distances over which enhancers can operate. Alternatively, there may be multiple enhancer sequences, each associated with a *J_α* gene segment. (3) Three *J_α* gene segments, *J_α37*, *J_α57* and *J_α61*, are closely linked and seem to be most closely related to one another (see ref. 18). This observation suggests that the *J_α* gene segments fall into subfamilies, like the *V_α* gene segments. Hence, the duplication, expansion and diversification of *J_α* gene segments may also arise from unequal crossing-over, gene conversion and single base substitutions. (4) As T cells may not use somatic hypermutation²⁴, there seem to be compensatory mechanisms for increased diversification of the 3' ends of the *V_β* and *V_α* genes. In the β-genes this occurs in the increased repertoire of *J_β* gene segments and the extensive use of the *D_β* gene segments in all three translational reading frames²⁴. In the α-genes this occurs in the extensive *J_α* repertoire.

We thank Marilyn Tomich and Dr Suzanna Horvath for the synthetic oligonucleotides, Henry Sun for the B10.D2-H-2^{dml} cosmid library, Debbie Maloney and Marty Garcia for technical

assistance, and Gerald Siu, Drs Richard Barth, Sandra Chang, Joan Kobori, Mitchell Kronenberg, Ulf Landegren, Nilabh Shastri and Martha Zuniga for critical reading of the manuscript. We also thank Dr Daniel Hansburg for providing the cytochrome *c/I-E_αE_β*-specific 1.9.2 T-helper hybridoma for the construction of cDNA and genomic libraries, Gerald Siu for stimulating discussions and Bertha Jones, Connie Katz and Susan Mangrum for preparation of the manuscript. This work was supported by a grant from the NIH and by T Cell Sciences, Inc.

In the accompanying papers, Hayday *et al.*⁴⁷ and Yoshikai *et al.*⁴⁸ have made similar observations concerning the organization of α genes in mice and humans, respectively.

Organization and sequences of the variable, joining and constant region genes of the human T-cell receptor α -chain

Yasunobu Yoshikai, Stephen P. Clark, Sheryle Taylor, Uik Sohn, Bonnie I. Wilson, Mark D. Minden & Tak W. Mak

The Ontario Cancer Institute and Departments of Medical Biophysics and Immunology, University of Toronto, Toronto M4X 1K9, Canada

An essential property of the immune system is its ability to generate great diversity in antibody and T-cell immune responses. The genetic and molecular mechanisms responsible for the generation of antibody diversity have been investigated during the past several years^{1,2}. The gene for the variable (V) region, which determines antigen specificity, is assembled when one member of each of the dispersed clusters of V gene segments, diversity (D) elements (for heavy chains only) and joining (J) segments are fused by DNA rearrangement¹⁻³. The cloning of the β -chain of the T-cell antigen receptor^{4,5} revealed that the organization of the β -chain locus, which is similar to that of immunoglobulin genes⁶⁻¹² is also composed of noncontiguous segments of V⁷⁻⁹, D^{10,11}, J^{8,9,11} and constant (C) region genes⁶⁻¹². The structure of the α -chain seems to consist of a V and a C domain connected by a J segment¹³⁻¹⁶. We report here that the human T-cell receptor α -chain gene consists of a number of noncontiguous V and J gene segments and a C region gene. The V region gene segment is interrupted by a single intron, whereas the C region contains four exons. The J segments, situated 5' of the C region gene, are dispersed over a distance of at least 35 kilobases (kb). Signal sequences, which are presumably involved in DNA recombination, are found next to the V and J gene segments.

Southern gel analysis¹⁷ was performed using human genomic DNA and nucleotide probes corresponding to the V, J and C region sequences of a human T-cell receptor α -chain cDNA, pY14 (ref. 16). We find that the entire pY14 insert hybridizes to ~10 fragments when genomic DNA is digested with *Eco*RI, *Bam*HI, *Hind*III or *Bgl*II (Fig. 1). Using a C-region-specific probe or J-region-specific probe, only one or two of these bands can be assigned to the C and J sequences (data not shown), whereas the rest correspond to fragments homologous with V gene segments. These results suggest the presence of only one C region and multiple V gene segments.

Seventeen recombinant phage from a human genomic library (from ref. 18) carrying inserts that hybridized to the V region of pY14 (*V_αpY14.1*) under non-stringent hybridization conditions were isolated. The nucleotide sequence was determined for one clone (λV13). Figure 2 shows the nucleotide sequence of this V gene segment, *V_αpY14.2*, which is divided into two exons. The first exon stretches from amino acids 1 to 15 and includes most of the presumptive signal peptide, whereas the second exon begins at amino acid 16 and ends at amino acid 113. The intron is 101 nucleotides long. Sequences that resemble the heptamer (CACAGTG) and nonamer (ACACAAACC) recognition signals that are involved in the recombination of immunoglobulin¹⁻³ genes and T-cell receptor β -chain genes⁶⁻¹² are next to the 3' end of the second exon, and are separated by 22 nucleotides. The complementary DNA sequence *V_αpY14.1* and the germline sequence *V_αpY14.2* are identical at 251 out of 279 nucleotides (90%) in the protein-coding region, and are identical at 76 out of 93 amino acids (82%). This may not be the gene segment that encodes the pY14 V region.

The results of Southern blotting (see Fig. 1) suggest that there is only one germline C_α gene. To characterize the C region at the molecular level, four λ clones that hybridize with the C region were isolated. Two of these (clones 8 and 18) also hybrid-

Fig. 1 Southern gel analysis of the V, J and C region genes in human genomic DNA was digested with restriction enzymes, *Eco*RI (lane 1), *Bam*HI (lane 2), *Hind*III (lane 3) and *Bgl*II (lane 4) and analysed by Southern blot^{16,17} using radioactive probes from: (1) the complete pY14 cDNA from Jurkat T-cell line (ref. 16), (2) an oligonucleotide corresponding to the J region sequence (nucleotides 545-593 in Fig. 4 of ref. 16); and (3) the C region probe alone (*Hpa*II/*Hpa*II fragment at nucleotides 591-980 in Fig. 4 of ref. 16). The results using the complete pY14 cDNA probe are shown, but the fragments corresponding to the C and J segments are denoted.

Fig. 2 Nucleotide sequence of a germline V segment *V_αpY14.2* of the human T-cell receptor α -chain genes. Seventeen λ recombinant clones in the human genomic library¹⁸ homologous with the V sequences of pY14 (ref. 16), *Eco*RI/*Sau*3A fragment of pY14 (nucleotides 1-529 in Fig. 4 of ref. 16) were identified by hybridization and washed at 5×SSC, 42°C. One clone, λV13, which contains a 1.3-kb *Eco*RI fragment, hybridized in stringent conditions (0.11×SSC, 68°C). The insert was sequenced using the Sanger dideoxy method²⁴. For the detailed sequencing procedure, see ref. 25. Ex, exon with recombinational signals overlined; underline, splicing signals of AG and GT, arrow, end-of-signal peptide. Differences in nucleotide and deduced amino acids of *V_αpY14.1* from cDNA pY14 (ref. 16) are denoted below the sequences of *V_αpY14.2*.

ized to a J sequence probe of pY14 (*J_αpY14*). Using the technique of 'chromosome walking', λ-clones 21 and 22 were also obtained. A detailed restriction enzyme map of these clones was determined (Fig. 3A). Regions that hybridized with oligonucleotides to α -chain human and murine *J_α* sequences (refs 13-16) are also indicated. The C region is mainly contained on a 5.7-kb

A

Diagram A illustrates the genomic organization of the human $\alpha 1(I)$ procollagen gene. The top line represents the full gene structure, with exons numbered 1 through 28. Introns are indicated by lines with arrows. Below this, the structure of the $\alpha 1$ gene is shown in λ clone 21 and λ clone 22. λ clone 21 contains exons 1 through 17, while λ clone 22 contains exons 1 through 17 and exon 18. A scale bar indicates 1 kb.

B

Diagram B illustrates the structure of the $\alpha 1(I)$ gene in the λ clone 21 and λ clone 22. The top line shows the structure of the $\alpha 1$ gene in λ clone 21, with exons numbered 1 through 28. Below this, the structure of the $\alpha 1$ gene is shown in λ clone 22, with exons numbered 1 through 28. A scale bar indicates 4 kb.

Ex 4

The regions of λ -clones 8, 21 and 22 that hybridize to J_{α} probes are indicated in Fig. 3A. The 3'-most J region that was identified lies close to the 5' end of a 3.6-kb *Bam*HI fragment ~4 kb upstream of the C_{α} gene. This J region hybridizes to a J_{α} pY14 probe under stringent conditions. The sequence of the 3.6-kb *Bam*HI fragment is presented in Fig. 5a. A sequence identical to the J segment of pY14 is found at nucleotides 509–565. Immediately 5' are the heptamer and nonamer recombination signals (CACAGTG and GGTTATCTC, respectively) separated by a 12-nucleotide-long spacer. These sequences are the same as the signal sequences for recombination that are found in immunoglobulin¹⁻³ and the β -chain of the T-cell receptor⁶⁻¹². Examination of the 3.6-kb sequence indicates that two other sequences can be found, including the highly conserved central Phy-Gly-X-Gly sequence. The first of these, from 1,407 to 1,462, is unlikely to be a functional J element because the putative splice donor site is not positioned to maintain the proper reading frame when joined to the C_{α} region. It also has poorly recognizable heptamer and nonamer signal sequences. The second other potential J_{α} segment, from 2,367 to 2,423, matches J_{α} pY14 at 9 of 19 amino acids and has a potential splice donor site at the proper position; however, the heptamer and nonamer sequences do not match the expected sequence very well. An *Alu* repetitive element spans positions 970–1,200 of the 3.6-kb *Bam*HI fragment. Hybridization analysis using oligonucleotide probes to murine and human J sequences indicates that ~12 human J_{α} sequences (Fig. 3A) may be scattered over these three

A clones (8, 21 and 22). To confirm that at least some of these are *J* sequences, regions denoted *b*, *c*, *d*, *e* and *f* in Figure 3A were also sequenced. Their *J* sequences are illustrated in Fig. 5b-f. It is clear that all these sequences have easily identifiable heptamer and nonamer recombination signal sequences; the highly conserved central Phy-Gly-X-Gly and splice sequences at the 3' end match the concessive sequence well. The sequence illustrated in Fig. 5f is not complete as it is at the end of clone 22. More recent experiments also show that *J_α* sequences extend further 5' to these clones. These *J_α* segments are longer than

Smooth muscle α -actin is a transformation-sensitive marker for mouse NIH 3T3 and Rat-2 cells

John Leavitt*, Peter Gunning†, Larry Kedest† & Raxit Jariwalla*

* Armand Hammer Cancer Research Center, Linus Pauling Institute of Science and Medicine, Palo Alto, California 94306, USA

† The MEDIGEN Project, Department of Medicine, Stanford University School of Medicine and Veterans Administration Medical Center, Palo Alto, California 94304, USA

Heteroploid mouse NIH 3T3 fibroblasts and several rat fibroblast strains (Rat-1, Rat-2 and REF-52) are cell lines of special interest in the field of carcinogenesis because of their extensive use as normal cells in transformation assays for putative cancer-causing genes. Exposure of these cells to carcinogenic chemicals or oncogenic DNA produces anchorage-independent cells with retracted cytoplasm that lack actin cables¹⁻⁷. All human fibroblast strains, normal and transformed, synthesize two electrophoretic forms of actin (β - and γ -actin)⁸⁻¹⁰. In contrast, we discovered that early-passage mouse and rat strains synthesize abundant amounts of each of the three electrophoretic forms of actin (α -, β - and γ -actin) but mouse and rat cancer cells express only β - and γ -actins. We now show that in NIH 3T3 and Rat-2 fibroblasts a third actin, the smooth muscle α isoform, is abundantly co-expressed with β - and γ -actin. In every instance tested following transformation to tumorigenicity, the accumulation of α -actin messenger RNA and α -actin synthesis was greatly inhibited. Shut-down of α -actin expression thus appears to be a reproducible transformation-sensitive marker in rodent fibroblasts.

Figure 1 shows the actin peptides made in untransformed and transformed NIH 3T3 and Rat-2 cells. Using computerized microdensitometry¹¹, we estimate that NIH 3T3 cells synthesize a considerable amount of α -actin, about 25-30% as much as β -actin, and Rat-2 cells synthesize about 25-40% as much α -actin as β -actin. All 68 Rat-2 subclones examined synthesized more α -actin than the parental Rat-2 strain (Fig. 1). The ratio of the rates of α -actin to β -actin synthesis increased from 0.25 to 0.42 as a consequence of subcloning. We and others³ have observed that Rat-2 subclones exhibit flatter, more contact-inhibited monolayers than the parental Rat-2 strain. Thus elevation in the rate of α -actin synthesis is associated with the acquisition of the flatter, more contact-inhibited phenotype on subcloning of Rat-2 cells.

We isolated transformed NIH 3T3 or Rat-2 cell lines from rare foci that arose spontaneously in confluent monolayers. Two such spontaneously transformed cell lines, T-3T3 and FocT, exhibit no α -actin (Fig. 1). We excluded the possibility that these spontaneous transformants arose from a subpopulation of non-transformed cells that do not make α -actin by screening 68 subclonal Rat-2 lines. Each line synthesized α -actin at about the same rate as the Rat-2 subclone shown in Fig. 1. Thus α -actin is a uniformly abundant gene product in Rat-2 cells and in NIH 3T3 cells.

A similar loss of α -actin was detected in all *in vitro*-transformed cell lines that we have examined to date. These additional lines include four separate EJ-Ha-ras oncogene transformed⁴ NIH 3T3 lines, one additional spontaneous transformant of Rat-2, two separate Rat-2 strains transformed with EJ-Ha-ras oncogene, a line transformed by transfection of Rat-2 cells with

Fig. 1 Autoradiograms of the cellular α -, β - and γ -actin polypeptides of normal and transformed NIH 3T3 and Rat-2 cells separated and resolved by two-dimensional polyacrylamide gel electrophoresis. An ampoule of frozen NIH 3T3 cells² was obtained from Dr Brian Crawford (Los Alamos National Laboratory) who received his 3T3 stock from Dr Esther Chang (Uniformed Services Medical School, Bethesda). The 3T3 stock was cultured through two passages at Los Alamos before preparation of the frozen ampoule used as the seed stock for the present study. The Rat-2 cell line¹ was from Dr Greg Reyes (Stanford University) who obtained his stock from Dr Mike Botchan (University of California, Berkeley). T-3T3 and FocT cell lines were derived from spontaneous foci that appeared in confluent monolayers of NIH 3T3 and Rat-2 cells, respectively. The two focus-derived cell lines were isolated from the focus by adsorption to a 3-mm Whatman filter paper disk which had been soaked in EDTA-trypsin solution (0.25% trypsin, 0.1 mM EDTA). Both cell lines are composed of highly refractile, morphologically transformed cells that produce rapidly growing tumours visible 1 week after subcutaneous inoculation of 2×10^6 cells into nude mice or syngeneic animals. The 'Rat-2 subclone' was a hypoxanthine-aminopterin-thymidine (HAT)-resistant clonal cell line induced by transfection of Rat-2 cells with a cloned thymidine kinase gene (J.L. and R.J., in preparation). All cell cultures were labelled with ³⁵S-methionine for 4 h². Total proteins were solubilized in Lysis A solution^{9,10,24} and the actin polypeptides separated by two-dimensional electrophoresis²⁴. Identification of the actin polypeptides is based on their abundance and relative position in the two-dimensional gel.^{8-10,14,17,18,24,25}

a cloned transforming DNA fragment (*Bam*HI-E) from human herpes simplex virus type 2 (ref. 12 and B. Tanczos *et al.*, in preparation), and four separate transformed cell lines induced by transfection of Rat-2 cells with a combination of cloned transforming DNA fragments (*Xba*I/*Bam*HI fragments EJ and EM) from human cytomegalovirus strain Towne (ref. 13 and R.J. *et al.*, in preparation).

In addition, Franza and Garrels¹⁴ have reported the same finding for rat embryo fibroblasts (REF-52 strain) transfected with the transforming genes of human adenovirus, Kirsten murine sarcoma virus, and simian virus 40. Mouse L-cells, which are highly transformed fibroblasts, also lack α -actin¹⁵.

To confirm α -actin expression in NIH 3T3 and Rat-2 cells, we demonstrated that an α -like actin RNA transcript is present in these cells but is greatly diminished or absent from the transformed cell lines. Figure 2 shows RNA transfer blot hybridization experiments in which total RNA from each cell type has been separated electrophoretically and then hybridized with isotype-specific RNA probes¹⁶ for β -actin (Fig. 2b) or γ -actin (Fig. 2c), or an actin coding sequence probe (Fig. 2a, d). mRNA transcripts for β - or γ -actin are 2,100 base pairs (bp) long^{15,16}. RNA transcripts that code for the three muscle-related α -actins are about 1,600-1,700 bp long¹⁵⁻¹⁸. With the β - and γ -actin-specific probes, only a 2,100-bp transcript was found

Table 1 Modulation of actin mRNA synthesis

		Relative amounts of α -, β - and γ -actin mRNAs

Relative amounts of the actin mRNAs were measured by hybridization with actin-coding or isotype-specific ³²P-DNA probes.

* Relative hybridization of an actin-coding region ³²P-DNA probe (Fig. 2) to either the 2,100-bp β -plus γ -actin mRNA band or the band representing the 1,600–1,700-bp α -actin in RNA in the RNA transfer blots shown in Fig. 2a,d; unsaturated autoradiographic bands resulting from α -specific or β -, γ -specific hybridization were quantified by computerized microdensitometry and the ratio of these measurements is shown.

† Hybridization of β -actin-specific ³²P-DNA probe to the 2,100-bp β -actin mRNA shown in Fig. 2b was quantified by computerized microdensitometry; the amount of hybridization for each total RNA isolate is expressed as a ratio—the amount of hybridization to mRNA from the derivative cell line relative to the amount of hybridization to mRNA from the parental cell line, either NIH 3T3 or Rat-2; or hybridization of the γ -actin-specific ³²P-DNA probe to 2,100-bp γ -actin mRNA as shown in Fig. 2c.

‡ Ratio of γ -actin-specific hybridization (Fig. 2c) to β -actin-specific hybridization (Fig. 2b), or the modulation in amount of γ -actin mRNA accompanying transformation if the amount of β -actin mRNA is kept constant.

§ Derived from a focus that arose spontaneously in a confluent Rat-2 or NIH 3T3 cell monolayer.

¶ BamHI fragment E (ref. 12).

|| Mixture of XbaI/BamHI fragments EJ and EM¹³.

Fig. 2 Autoradiograms of total RNA transfer blots hybridized with ³²P-DNA probes derived from an actin-coding sequence or isotype-specific 3'-untranslated region (3'UTR) sequences. In a and d, the probe was a PvuII/XbaI DNA fragment from pHM α A-1 (ref. 27) containing the coding region of human skeletal α -actin from amino acid 202 to amino acid 374. This probe hybridizes equally well with muscle and non-muscle actin mRNAs (data not shown). In b, the probe was the human β -actin-specific subclone pHF β A-3'UT¹⁶ and in c the probe was the human γ -actin-specific subclone pHF γ A-3'UT¹⁶. The cell source of total RNA in each electrophoretic lane is as follows: lane 1, T-3T3; lane 2, normal NIH 3T3; lanes 3 and 7, normal Rat-2; lane 4, Rat-2 subclone (Fig. 1); lanes 5 and 8, FocT; lane 6, mouse skeletal muscle^{15,16}; lane 9, RXBJMT1 (Table 1); lane 10, RBET (Table 1); lane 11, RXBJMT2 (Table 1); lane 12, RXBJMT3 (Table 1); and lane 13, RXBJMT4 (Table 1).

Methods. Total RNA (2 μ g) was isolated from each cell line, size-fractionated on 2.2 M formaldehyde-1% agarose gels and blot-transferred to nitrocellulose filters as described previously²⁸. The filters were hybridized with one of three different nick-translated²⁹ DNA probes. Hybridization was done in 4 $\times$ SSC, 50 mM Na₂HPO₄ (pH 7.0), 5 $\times$ Denhardt's³⁰, 10% (w/v) dextran sulphate containing 10⁶ d.p.m. radiolabelled DNA probe per ml at 65 °C. Following hybridization, the filters were washed with five changes of 0.5 $\times$ SSC, 0.1% (w/v) SDS and exposed to Kodak XAR-5 film.

(Fig. 2b, c). With the nonspecific actin-coding probe, an abundant, 1,600–1,700-bp transcript is detected in normal NIH 3T3 and Rat-2 cells, together with the 2,100-bp transcripts for β - and γ -actin (Fig. 2a, d). This result firmly establishes the presence of a third expressed actin mRNA in these cells. The presence of a third actin mRNA also excludes the possibility that the α -actin identified in two-dimensional gels was a post-translationally modified product of β - or γ -actin. Perhaps a trace of α -like transcript is detectable in the transformed NIH 3T3 strain (Fig. 2a, lane 1) but no α -like transcript is found in the transformed Rat-2 strain (Fig. 2a, lane 5). In addition, the herpes simplex virus 2- and four cytomegalovirus-trans-

formed Rat-2 cell lines contain no α -like transcript (Fig. 2d, lanes 9–13; Table 1).

In an attempt to identify which α -actin isoform is expressed in NIH 3T3 and Rat-2 cells, we hybridized replicate RNA blots with 3'-untranslated region probes specific for α (skeletal)- and α (cardiac)-actin mRNA¹⁶; no transcripts were detected (not shown). Thus we conclude by elimination that the α -actin expressed in NIH 3T3 and Rat-2 cells is not β -, γ -, α -skeletal or α -cardiac and is probably the α -actin made in smooth muscle¹⁹. We cannot exclude the formal possibility that the α -actin is an as yet undefined α -actin isotype. However, Vanderkerckhove and Weber²⁰ have demonstrated that cultured

chick embryo fibroblasts synthesize smooth muscle α -actin in addition to non-muscle β - and γ -actin. This prior observation strongly supports the conclusion that the α -actin we detect in rodent fibroblast cell lines is also of the smooth muscle type.

In the spontaneously transformed Rat-2 cell line FocT there was an additional unexpected change in actin expression. Rat-2 cells accumulate less γ -actin than β -actin (Fig. 1), so that the ratio of γ -actin to β -actin is 0.4. The spontaneously transformed Rat-2 cell line accumulates more γ -actin than β -actin, amounting to a threefold up-regulation of γ -actin relative to β -actin (Fig. 1). The amount of γ -actin mRNA is up-regulated even more dramatically relative to the β -actin mRNA (Fig. 2b, c, lane 5). Assuming that these changes are not related to altered mRNA stability, we estimate that the rate of γ -actin gene transcription has increased 8-13-fold in this transformed strain (Table 1).

To examine the relative significance of the actin protein modulations, we have analysed the 500 most abundant polypeptide species in high-resolution two-dimensional gels of total proteins from most of the normal and transformed Rat-2 cells discussed in the present paper. We consistently find no qualitative changes in polypeptide synthesis by Rat-2 cells other than the loss of α -actin. The same finding is implied by Franza and Garrels¹⁴, although they and Matsumura *et al.*²¹ also report that the microfilament-associated tropomyosin subunits of REF-52 are modulated quantitatively but variably among different types of transformed cells. Thus, at least among the 500 abundant cellular proteins of rat fibroblasts, the alterations of actin expression are not a general phenomenon shared by other proteins.

Rat-2 and NIH 3T3 cells are similar in their shape and relatively flat morphology¹, they are both aneuploid^{1,2}, and will consistently form subcutaneous tumours in syngeneic animals, but only after long latent periods of 10-12 weeks (J.L. and R.J., unpublished results). By contrast, all of the transformed cell lines mentioned in this study produce, within 1-3 weeks, solid tumours that grow rapidly to a mass 4 cm in diameter by 4-5 weeks. Morphologically these transformed cells are typical of other transformed cells^{3-8,12-14,22} but contrast with untransformed Rat-2 and NIH 3T3 cells in that their cytoplasm is retracted and refractile on the plastic substratum. Thus modulations in actin expression and abundance of the types described in this study are associated with microfilament rearrangement and subsequent alterations in cell shape, leading to elevation of tumorigenic potential. Indeed, one acute transforming oncogene of the Gardner-Rasheed feline sarcoma virus encodes the N-terminal amino-acid sequence (130 residues) of actin²³. This finding supports the hypothesis that alteration of the microfilament system through qualitative changes in actin expression^{8-10,14,22-26} or organization^{7,8,26} may be an important aspect of the neoplastic transformation process.

We thank David Goldstein for technical assistance in gel and computerized microdensitometry analyses. This work was supported in part by an ACS grant (NP-433) and a grant from the NCI (CA43763) to J.L., and by grants from NIH (HD17031) and the Veterans Administration to L.K.

The Duchenne muscular dystrophy (DMD) locus has been localized to the short arm of the human X chromosome (Xp21) by detection of structural abnormalities¹⁻⁵ and by genetic linkage studies⁶⁻⁸. A library highly enriched for human DNA from Xp21 was constructed⁹ using DNA isolated from a male patient who had a visible deletion and three X-linked disorders (DMD, retinitis pigmentosa and chronic granulomatous disease)⁵. Seven cloned DNA probes from this library and the probe 754 (refs 5, 8) are used in the present study to screen for deletions in the DNA isolated from 57 unrelated males with DMD. Five of these DMD males are shown to exhibit deletions for one of the cloned DNA segments and at least 38 kb of surrounding DNA. In addition, two subclones from the same region detect four restriction fragment length polymorphisms which exhibit no obligate recombination with DMD in 34 meiotic events. These new DNA segments will complement the existing Xp21 probes⁴⁻⁹ for use in carrier detection and prenatal diagnosis of DMD. Elucidation of the end points of the five deletions will help delineate the extent of the DMD locus and ultimately lead to an understanding of the specific sequences involved in DMD.

The DNA of 57 unrelated DMD males was tested for deletions of the following 8 cloned DNA segments absent from the male patient with a visible deletion⁵: pERT55-2, pERT84, pERT87, pERT145, pERT378, pERT379, pERT469 and 754 (pERT, plasmids isolated from a library enriched for Xp21 DNA segments⁹). Based on a previously described strategy, 8 probes from a small region of the genome should increase the probability that one probe will detect a small deletion at a specific locus in the region¹⁰. Among the 8 clones tested, only one, pERT87, was found to be absent from the DNA of 5 of the 57 unrelated DMD males.

pERT87 was screened by hybridization¹¹ against total human genomic libraries constructed in Charon 35 (ref. 12) and EMBL-3 (ref. 13) to obtain more surrounding DNA. After chromosomal

Fig. 1 **a**, Schematic map of 41 kilobases of genomic DNA around the original 200 base pairs, pERT87 (0 on kb scale). The subcloned segments that were free of human repeated sequence elements are indicated numerically below the block diagram, and the size of the segment is represented by an open block. Segments containing highly repeated sequences are indicated as darkened areas, and those containing moderately repeated segments as cross-hatched areas. **b**, Southern blot¹⁴ analysis of DNA from seven males with DMD. Lanes 1-7 contain *Pst*I-digested DNA of the patients. Two identical nitrocellulose filters were hybridized with pERT87-18 and pERT87-1. The same filters were then rehybridized with pERT87-8 and pERT55-2, respectively. The autoradiographs are presented as separate segments of each original autoradiograph. The fragment hybridized is indicated to the left of the figure; the sizes of hybridizing fragments are indicated on the right and were calculated from ³²P-end-labelled *Hind*III-cleaved λ DNA. The numerical designation of the subclone used as a probe and the probe's relative position in 'walked' DNA are indicated in **a**. The designation above each lane is the nomenclature for each DMD male.

Methods. Five overlapping bacteriophage clones (lines with arrows below kb scale) were isolated¹¹ from two total human DNA recombinant libraries constructed in Charon 35 (ref. 12) and EMBL-3 (ref. 13) (generously provided by Drs S. Orkin and Y. Shiloh, respectively). Each library was constructed from size-selected (13-21 kb) partially *Mbo*I-digested human DNA and the respective phage vector. Screening¹¹ was against nitrocellulose filters lifted from primary plates (the libraries were never amplified). Hybridizing phage were plaque-purified and *Hind*III-digested human DNA segments were subcloned²² into *Hind*III-cleaved and dephosphorylated pBR322 (New England Biolabs). The subclones were digested with various restriction enzymes (*Eco*RI, *Xba*I and *Kpn*I) to yield smaller fragments free of human repetitive sequence elements. Genomic DNA was isolated from cell nuclei of whole blood leukocytes as described previously⁷ and digested with *Pst*I in buffers recommended by the manufacturer. The digested DNA (1.5 μ g) was separated by electrophoresis on a horizontal 0.7% agarose gel and transferred to nitrocellulose¹⁴. The unique-sequence subclones pERT87-18, pERT87-8, pERT87-1 and pERT55-2 were ³²P-radiolabelled using T4 DNA polymerase and radiolabelled fragments were recovered from low melting point agarose gels⁷. Prehybridization of nitrocellulose filters was undertaken as described previously⁷ and hybridization was at 45 °C in 50% deionized formamide, 4 $\times$ SSC (1 $\times$ SSC = 0.15 M NaCl, 0.015 M Na citrate), 0.05 M sodium phosphate buffer (pH 6.8), 8% dextran sulphate, 10 $\times$ Denhardt's, 100 μ g ml⁻¹ transfer RNA, 25 μ g ml⁻¹ sheared salmon sperm DNA, 0.1% SDS, 1 mM EDTA and 10⁶ c.p.m. ml⁻¹ of radiolabelled DNA. Filters were washed in 0.1% SDS and 0.1 $\times$ SSC several times at room temperature and then for 1 h at 55 °C. Autoradiography was at -70 °C with a DuPont intensifying screen for 1-5 days.

'walks' in both directions from the original pERT87 clone, five bacteriophage clones were isolated which had a combined insert size of 41 kilobases (kb) (Fig. 1a). Small unique-sequence subclones from the recovered pERT87 human inserts were hybridized¹⁴ to *Pst*I- or *Taq*I-cleaved DNA of the 57 DMD males. The results for the five deletions are presented in Fig. 1b together with results from two DMD boys who do not bear deletions of the pERT87 region. The subclones pERT87-18, pERT87-8 and pERT87-1 are absent from the DNA of these five unrelated individuals (Fig. 1b, lanes 2-6). These three subclones span a region of 38 kb of genomic sequences (see schematic map, Fig.

Table 1 Detection of deletions in DMD males

	Total	Deletions
DMD X chromosomes		
Familial origin	17	3 (18%)
Sporadic origin	40	2 (5%)
Total	57	5 (9%)
Normal X chromosomes	61	0

The DNA isolated from 57 DMD males, 47 normal males and 7 normal females was cleaved with *Pst*I or *Taq*I. Diagnosis of DMD was established by characteristic history, physical examination, increased CPK levels and a positive muscle biopsy²¹. None of the five boys with deletions exhibited mental retardation, developmental delay, recurrent infections or retinal abnormalities. Following separation of digested DNA by electrophoresis, the DNA samples were transferred to nitrocellulose and hybridized with pERT87 phage subclones or other Xp21 cloned DNA fragments as described in Fig. 1 legend. All 57 DMD X chromosomes were tested for deletion of the pERT87 region, as were all 61 normal X chromosomes. In some cases only 37 DMD males were tested for deletion of other pERT clones or 754, but all 5 boys deleted for the pERT87 region were tested for deletion at other pERT and 754 loci. Only the pERT87 region was found to be deleted in any of the 57 DMD males. Deletions were defined as complete absence of hybridization of a cloned fragment to any restriction fragment in a particular endonuclease digest. In all cases at least one other pERT clone or 754 was shown to be present on the same nitrocellulose filter on which the pERT87 region exhibited deletion. Familial cases of DMD were determined either by extensive family history of DMD or, in a few cases, by elevated CPK^{15,16} in mothers of DMD males. Sporadic cases were those where no elevated CPK was observed in a mother with no family history of the disease. Normal individuals were defined as fathers of males with DMD or other X-linked diseases, random normal individuals or, in some cases, individuals affected by other X-linked diseases.

1a) and therefore give a lower limit of 38 kb to all five deletions. If the deletion in the male patient⁵ lacking all eight DNA fragments is 2,000-5,000 kb and if the eight cloned fragments are uniformly distributed within the deleted region in normal DNA, then an upper estimate of the five deletions detected by pERT87 is 250-600 kb.

The five deletions detected represent 9% of DMD males tested. Of 61 normal X chromosomes (47 males and 7 females), no deletions were found in the pERT87 region (Table 1). Among the boys who were found to have deletions, two were sporadic cases of DMD with no previous family history. The other three were familial cases of DMD (determined by elevated creatine phosphokinase (CPK) levels in suspected carrier females^{15,16} or a family history of DMD). The results given in Table 1 and Fig. 1b are consistent with results obtained with two other X-linked disorders, Lesch-Nyhan syndrome¹⁷ and ornithine transcarbamylase (OTC) deficiency¹⁸, in which 18 and 6.6% of patients were found to have partial or complete deletions of genomic DNA sequences complementary to the cloned cDNAs for hypoxanthine-guanine phosphoribosyltransferase and OTC, respectively.

Several unique subclones from the pERT87 region were hybridized to nitrocellulose filters containing immobilized DNA samples isolated from four unrelated females cleaved with 24 different restriction enzymes⁷. The subcloned probe pERT87-8 (a 1.3-kb *Xba*I fragment next to the original pERT probe, pERT87; see Fig. 1a) was found to recognize both a *Bst*XI and a *Taq*I restriction fragment length polymorphism (RFLP). Figure 2a shows the segregation of the *Bst*XI RFLP and demonstrates mendelian inheritance with no obligate recombinants in five meiotic events. The segregation of the *Taq*I RFLP (Fig. 2) shows no obligate recombination in six meiotic events. To date, the 2 RFLPs seen by pERT87-8 have not recombined in 34 meiotic events in 10 DMD families. A lod score was calculated¹⁹ based on segregation results of the two pERT87-8 RFLPs in these 10 DMD families (two presented here); there were seven meioses in which the phase was known and 24 in which it was not known. The only female individuals who were judged to be carriers or normal on the basis of CPK levels are those presented

Fig. 2 Segregation of pERT87-8 in DMD families. **a**, DNA was isolated from individuals within a family in which the DMD trait segregated (indicated by darkened symbols), and the DNA was cleaved with *Bst*XI. Electrophoresis, blotting and hybridization were as described for Fig. 1b. On *Bst*XI digestion of genomic DNA, pERT87-8 hybridizes to 4.4- and 2.2-kb *Bst*XI fragments in females heterozygous for the RFLP. The 4.4-kb fragment is observed in 60% of X chromosomes and the 2.2-kb fragment in 40% of X chromosomes (28X chromosomes tested). The carrier mother exhibits the heterozygous pattern of the 4.4/2.2-kb *Bst*XI alleles, as do her two carrier daughters (lanes 2, 4). The lower allele (2.2 kb) is present in both affected DMD probands (lanes 5, 6) while the upper allele (4.4 kb) is present in the unaffected son (lane 3). The father in this family has a 4.4-kb *Bst*XI hybridizing fragment (data not shown). The female individuals in lanes 2 and 4 were suspected of being carriers of the DMD trait based on elevated CPK values^{15,16,21}. Fragment sizes were calculated by comparison with ³²P-end-labelled *Hind*III-cleaved λ phage DNA (shown in centre of figure). **b**, The DNA isolated from individuals of a family segregating the DMD trait was cleaved with *Taq*I. The pERT87-8 probe hybridizes to a 3.8-kb, 2.7-kb, 1.1-kb and 1.0-kb fragment in females heterozygous for the RFLP. The 1.0-kb *Taq*I fragment is present in all individuals, whereas the RFLP is revealed by the presence or absence of a *Taq*I site on a 3.8-kb fragment. The rarer allele is a 3.8-kb fragment (27% of X chromosomes), and the common allele is represented by 2.7- and 1.1-kb fragments (73% of X chromosomes tested). The carrier mother (lane 1) exhibits the heterozygous *Taq*I pattern of the 1.1-, 2.7/3.8-kb bands. Her three DMD carrier daughters (lanes 2-4), all of whom have affected sons, show two-copy hybridization to the large 3.8-kb allele, while the three suspected non-carrier daughters (based on their CPK values; lanes 5-7) exhibit the heterozygous pattern. This demonstrates that the X chromosome with the 3.8-kb allele from the carrier mother is inherited by the three carrier daughters along with the 3.8-kb allele from the father. The affected sons of these carrier women all inherited a 3.8-kb and a 1.0-kb *Taq*I fragment from their mothers (data not shown). Females were determined to be carriers of the DMD trait by elevated CPK and sons with DMD; non-carrier women were determined by normal CPK. The dark smudges between 2.7 and 1.1 kb in lanes 1-5 are nonspecific and are caused by the need to autoradiograph the nitrocellulose filter for 6 days to visualize the faintly hybridizing 2.7-, 1.1- and 1.0-kb fragments. These only occurred in this autoradiograph.

in Fig. 2; most results were obtained with affected or normal sons of obligate heterozygous DMD females. The coincidence of deletions for pERT87 and the DMD trait was not used in the calculation of lod scores. The calculated maximum lod score was 7.6 at $\theta = 0$ centimorgans at confidence limits, set by lod scores one unit lower, of 0 to 7 centimorgans. A more precise recombination fraction will take many more informative meioses.

To characterize more precisely the sporadic or familial nature of the deletions detected by the pERT87 probes, the *Bst*XI RFLP was used to tag specific X chromosomes in two families containing DMD boys bearing deletions. In the first family (sporadic), the mother (Fig. 3a, lane 5) of a DMD boy with a deletion (Fig. 3a, lane 4) is heterozygous for the *Bst*XI RFLP. This woman must have two copies of the pERT87-8 locus and is not heterozygous for the deletion. In the second family (familial), the grandmother (Fig. 3b, lane 1) is either hemizygous or homozygous for the 2.2-kb *Bst*XI allele, but her daughter (Fig. 3b, lane 2) has only the 4.4-kb allele, presumably inherited from her father. As the daughter has no hybridizing 2.2-kb allele which she should have inherited from her mother and as the hybridization intensity of the 4.4-kb allele is similar to that of a single X chromosome in the control female (Fig. 3b, lane 5), we presume that the daughter is heterozygous for the deletion evident in her two DMD sons (Fig. 3b, lanes 3, 4).

The *Bst*XI and *Taq*I RFLPs are predicted to be heterozygous in 48 and 39%, respectively, of women tested (allele frequencies

Fig. 3 Analysis of deletions for pERT87-8 in DMD families. **a**, DNA was isolated from a mother of a DMD boy with a deletion and from her sister. Electrophoresis of *Bst*XI-cleaved DNA and hybridization of pERT87-8 were as described in Fig. 1 legend. The open circles above lanes 3 and 5 indicate the two sisters and the darkened symbol above lane 4 represents the DMD son. An unrelated female heterozygous for the *Bst*XI RFLP is presented in lane 2. The sizes of hybridizing fragments given in the centre were calculated from a ³²P-end-labelled *Hind*III digest of λ DNA (lane 1). **b**, DNA isolated from the grandmother (lane 1), mother (lane 2) and two DMD sons (lanes 3, 4) was cleaved with *Bst*XI and the DNA hybridized with pERT87-8 as described in Fig. 1 legend. DNA isolated from an unrelated female heterozygous for the *Bst*XI RFLP is included in lane 5. The darkened symbols above the lanes indicate the DMD trait.

given in Fig. 2 legend). After identifying the pERT87-8 RFLPs, two additional RFLPs were found to be recognized by pERT87-1 (a 1.4-kb *Kpn*I/*Sal*I fragment 16 kb away from pERT87-8; Fig. 1a). Allele frequencies of these RFLP alleles have been determined and mendelian inheritance established. On *Xmn*I digestion, pERT87-1 detects 8.7- and 7.5-kb fragments in heterozygous females (allele frequencies 0.72 and 0.28, respectively). With *Bst*NI digestion, pERT87-1 detects fragments of 3.1 and 2.45 kb/0.65-kb fragments with an invariant 0.7-kb fragment in heterozygous families (allele frequencies 0.52 and 0.48, respectively). One or other of the pERT87-1 RFLP alleles was found to be useful in females from whom no useful information could be obtained using the pERT87-8 *Bst*XI or *Taq*I RFLPs. If there is no linkage disequilibrium of these four RFLPs at the pERT87 region, the expected combined heterozygosity is 0.90. The observed heterozygosity in women studied with all four RFLPs is slightly greater than 0.6. The pERT87-8 region has been mapped⁹ distal to the (X; autosome) translocation breaks within Xp21 in DMD females^{2,3} and should complement the existing proximal probe 754⁵ for use in carrier detection and prenatal diagnosis of DMD. The ability of pERT87-8 and pERT87-1 to distinguish tightly linked RFLP alleles in women at risk for DMD and detection of presumed deletions at the locus make these the most informative probes to date in following the DMD X chromosome.

The deletions detected by pERT87 subclones in the five unrelated DMD males provide a unique tool for defining the extent of the DMD locus. At present, all five individuals lack a minimum of 38 kb of genomic sequences. Expansion of the cloned region by chromosomal 'walking' on total genomic or sorted human X-chromosome bacteriophage libraries²⁰ should elucidate the extent of these deletions. Newly acquired unique-sequence DNA segments can be used to screen for additional deletions, structural rearrangements or new RFLPs. Determination of the common region deleted or rearranged in DMD males should define the exact location of the DNA sequences involved in DMD. Analysis of the cloned DNA from this region should lead to an understanding of the molecular mechanisms that give rise to the phenotype of DMD.

We thank Drs S.-P. Kwan and G. Bruns for contributing DNA isolated from normal males; Dr S. Latt for calculating the lod scores on the segregation of pERT87-8 alleles in DMD families; Drs J. Gusella, M. Bresnan and T. Brewster for providing DNA from DMD families, and Dr P. Pearson for providing the probe 754. Relationship between an enhancer element in the human antithrombin III gene and an immunoglobulin light-chain gene enhancer

Edward V. Prochownik

Section of Hematology/Oncology, Department of Pediatrics, C. S. Mott Children's Hospital and the Committee on Cellular and Molecular Biology, University of Michigan School of Medicine, Ann Arbor, Michigan 48109, USA

Enhancers, *cis*-acting transcriptional control elements have been described in both viral and cellular genes¹. They influence transcription in a quantitative fashion, act over relatively large distances (several kilobases, kb) and behave independently of their position and orientation. Enhancers have been described in immunoglobulin, chymotrypsin and insulin genes²⁻⁹. They bear little homology with each other except for an 8-base pair (bp) 'consensus' core element, GTGG^{AAA}_{TTT}G (refs 10, 11), but even this element is sometimes non-homologous⁹. I have searched for such elements in the human antithrombin III (AT-III) gene. AT-III is an important coagulation protein which inactivates thrombin¹². It is produced by the liver and, to a lesser extent, by the kidney¹³. Here, I report that the 5' flanking region of the AT-III gene encodes a segment homologous with the enhancer containing the joining-constant_κ (*J_κ-C_κ*) intron of immunoglobulin *κ*-chain genes. This extensive homology suggests the existence of regulatory factors that recognize common DNA sequences in lymphoid tissues and in those which express AT-III.

Two regions in the 5'-flanking region of the AT-III gene demonstrate sequence homology with sites in the *J_κ-C_κ* introns of murine or human immunoglobulin *C_κ* genes (Fig. 1). Region 1 corresponds to nucleotides 252-264 of the AT-III gene¹⁴ and to nucleotides 3,904-3,916 of the *J_κ-C_κ* intron of human and murine *C* genes^{15,16}. Ten of 13 residues (77%) were homologous in the AT-III and human *J_κ-C_κ* sequences and 9 of 13 residues (69%) were homologous in the AT-III and murine *J_κ-C_κ* sequence. A second, more extensive, region of homology (17 of 22 bases, 77%) was observed between nucleotides 291 and 312

Fig. 1 Homologies between the human AT-III 5'-flanking region and human and mouse *J_κ-C_κ* large introns. **a**, DNA sequence of the immediate 5' end of the AT-III gene. The sequence shown here is a portion of a 1.2-kb *Pst*I genomic subclone (pAT1.2) containing 304 bp upstream flanking region, 72 bp 5'-untranslated region and codons for the first 13 amino acids of the signal peptide¹⁴. The rest of the subclone contains ~800 bp of intervening sequence. The arrow at position 304 denotes the transcriptional start site. **b**, Sequence homologies between AT-III and *J_κ-C_κ* introns. In region 1, the AT-III sequence shown is that between nucleotides 252 and 264. The *J_κ-C_κ* sequence is that between nucleotides 291 and 312, according to the numbering system of Max *et al.*¹⁶. In region 2, the AT-III sequence is that between nucleotides 291 and 312 and the *J_κ-C_κ* sequence is that between nucleotides 3,868 and 3,892 (refs 15, 16). Underlined regions correspond to polyoma virus or core enhancer sequence homologies¹⁷⁻¹⁹.

of AT-III and nucleotides 3,869-3,892 of the murine *J_κ-C_κ* region, although homology with the human *J_κ-C_κ* region was not observed. Although regions 1 and 2 are short and homology could conceivably be fortuitous, it was striking that both regions bear similarities to known viral enhancer elements. For example, in region 1, the underlined area (Fig. 1b) is homologous with a portion of the polyoma virus enhancer TCTCCACCA¹⁷⁻¹⁹. Similarly, the underlined area in region 2 is homologous with the 'core' consensus sequence GTGG^{AAA}_{TTT}G, thought to be^{10,11} common to some eukaryotic viral enhancer elements. Thus, the 5'-flanking region of the human AT-III gene might contain functional enhancer activity; I tested this suggestion in an *in vivo* transfection assay using the chloramphenicol

Fig. 2 Construction of AT-III CAT vectors. pAT1.2 is the 1.2-kb AT-III genomic subclone described in Fig. 1 legend. The insert was excised with *Pst*I and ligated into the miniplasmid π VX³⁷ in such an orientation that the region containing the enhancer element was bounded by a 5' *Bgl*II site in the π VX polylinker and the 3' *Bam*HI site in IVS-1 of the AT-III gene. Following digestion of π VXAT1.2 with *Bgl*II and *Bam*HI, the 800-bp-long enhancer-containing fragment was ligated in both possible orientations into the *Bgl*II (upstream) or *Bam*HI (downstream) sites of the enhancerless CAT expression vector pA₁₀CAT₂. The resulting four constructs were designated pATCAT-E1-E4, with only orientations 1 and 3 shown here for simplicity. The arrows indicate the 5'→3' direction of the enhancer element in each of the constructs. Note that the relative proximities of the enhancer element to the CAT promoter are therefore E3>E4>E2>E1. P, *Pst*I; B, *Bam*HI; Bg, *Bgl*II; H, *Hind*III; X, *Bam*HI or *Bgl*II sites destroyed by ligation of nonregenerative GATC sticky ends. Before transfection studies, all plasmids were isolated by the alkaline lysis method³⁸ and doubly banded in CsCl to ensure complete removal of contaminating nucleic acids. Open box, AT-III-derived sequences; solid box, *J_κ-C_κ* enhancer-like region; solid lines, plasmid-derived sequences; stippled box, CAT gene; cross-hatched box; truncated SV40 enhancer region; 21, SV40 21-bp repeats.

acetyltransferase (CAT) assay²⁰. Restriction fragments containing the putative enhancer element from the AT-III gene were cloned into the enhancerless vector pA₁₀CAT₂ (Fig. 2) and their effect on transcription quantitated by examining cell extracts for the presence of CAT following transfection. A positive control plasmid, pSV₂CAT, contains a simian virus 40 (SV40) enhancer and directs the synthesis of large amounts of CAT. Each plasmid was transfected into four different eukaryotic cell lines, two of which, the COS-1 African green monkey kidney line²¹ and the Alexander human hepatoma line²² are derived from tissues that normally express AT-III (ref. 13). Cell extracts were prepared and assayed for CAT activity 48 h later²⁰. CAT activities were normalized to the results of Hirt extracts²³ to allow for variations in the transfected DNA uptake and replication. The results (Fig. 3) can be summarized as follows: (1) CAT activity was significantly enhanced above background by the

presence of 800 bp of AT-III gene sequence containing the *J_κ-C_κ* homologies; (2) the level of enhancement was generally in inverse proportion to the distance of the putative enhancer element from the SV40 early promoter, although some variability was seen between experiments; (3) enhancer activity was independent of the orientation of the AT-III sequences; (4) enhancer activity was seen only in those cells derived from tissues that naturally produce AT-III, that is, COS-1 (kidney) and Alexander hepatoma (liver). Examination of Hirt extracts of transfected cells showed only small differences in plasmid copy number within any single experiment, indicating that the increased CAT activity was not the result of preferential replication of enhancer-containing constructs in COS-1 cells or of variability in DNA uptake (my unpublished data). Therefore, I conclude that the 5' end of the human AT-III gene contains sequences that potentiate heterologous gene transcription in a tissue-specific manner when assayed by transient expression.

The extensive sequence homology observed between AT-III and immunoglobulin *J_κ-C_κ* enhancers suggested that there is also functional homology. This possibility was tested by introducing a murine immunoglobulin *J_κ-C_κ* enhancer into Alexander and COS-1 cells and the AT-III enhancer into a murine myeloma line and measuring CAT activity 48 h later. In the former case, the immunoglobulin *J_κ-C_κ* enhancer element was cloned into the *Bgl*II site of pA₁₀CAT₂. The resultant plasmid, designated pA₁₀CAT₂- κ , was then introduced into Alexander or COS-1 cells by calcium phosphate precipitation. The plasmids pA₁₀CAT₂- κ and pATCAT-E3 were transfected into 10⁷ M12 murine myeloma cells using the electroporation technique²⁴ and cell extracts were assayed for CAT after 48 h (Table 1). As observed previously, the AT-III enhancer functioned in both Alexander and COS-1 cells. In a similar fashion, pA₁₀CAT₂- κ also functioned above background when introduced into M12 cells. More significant, however, was the observation that the AT-III enhancer functioned in M12 cells and that the immunoglobulin *J_κ-C_κ* enhancer functioned in at least one of the cell lines (COS-1) derived from AT-III-producing tissues. CAT activity was generally less in the heterologous cells: the AT-III enhancer functioned better in COS-1 and Alexander cells whereas the *J_κ-C_κ* enhancer functioned better in M12 cells. pA₁₀CAT₂- κ functioned at only

Table 1 Relative activity of AT-III and *J_κ-C_κ* enhancers in myeloma cells, hepatocytes and COS-1 cells

Transfected plasmid	M12 myeloma	CAT activity in	
		Alexander hepatoma	COS-1
pATCAT-E3	4.0	4.3	12.8
pA ₁₀ CAT ₂	7.2	1.5	4.4
pA ₁₀ CAT ₂ - κ	1.0	1.0	1.0

Plasmid pATCAT-E3 is described in Fig. 2 legend. pA₁₀CAT₂- κ was constructed by removal of the 1.25-kb *Hind*III/*Hpa*I fragment from the rearranged murine gene MOPC-41¹⁶. The fragment was repaired with DNA polymerase (Klenow fragment) and deoxynucleoside triphosphates. *Bgl*II linkers were added, followed by ligation into the *Bgl*II site of pA₁₀CAT₂. The orientation was such that the former *Hind*III site was brought closer to the SV40 early promoter. 20 μ g of each plasmid was introduced into either Alexander or COS-1 cells by standard calcium phosphate DNA co-precipitation onto 5 $\times$ 10⁵ cells plates the day before. For M12 cells, transfection was accomplished by electroporation of 10⁷ myeloma cells in 0.5 ml phosphate-buffered saline (PBS). The procedure was essentially as described previously²⁴ using an Isco Model 494 electrophoresis power supply. Voltage was adjusted to 2,000 V, current to 0.9 mA and the adjustable current and wattage set at a minimum. Cells were kept at 0 °C in PBS during electroporation and for 10 min afterwards before being replated in modified Eagle's medium (NEM)/10% fetal calf serum (FCS). Following transfection, each cell line was grown for 48 h in MEM/FCS, at which time CAT activity was measured in extracts. The values shown represent the increase over the amount of CAT conversion seen after transfection with pA₁₀CAT₂ alone (value arbitrarily set at 1).

Fig. 3 Tissue-specific CAT expression. **A**, Kinetics of CAT activity in four different cell lines: **a**, COS-1; **b**, Alexander human hepatoma; **c**, HeLa; **d**, mouse thymidine kinase-negative L cells. Transfections were with pSV2CAT (●); pA₁₀CAT₂ (△); pATCAT-E1 (▲); pATCAT-E2 (■); pATCAT-E3 (○); pATCAT-E4 (□). All points in this and subsequent experiments are normalized for differences in plasmid copy number as determined by DNA dot-blots of Hirt extracts²³. **B**, Thin-layer chromatograms of CAT conversion products. Spots nearest the bottom represent unacetylated ¹⁴C-chloramphenicol. **a**, COS-1; **b**, Alexander; **c**, HeLa; **d**, L cells. From left to right in each lane, the products from transfections with pSV2CAT, pA₁₀CAT₂, pATCAT-E1, pATCAT-E2, pATCAT-E3 and pATCAT-E4, respectively, are spotted. In **c** the pA₁₀CAT₂ and pSV2CAT lanes have been reversed. Each set of experiments was performed at least twice with three different plasmid preparations.

Methods. All cells were grown in Dulbecco's modified Eagle's medium (MEM) supplemented with 10% fetal bovine serum, 2 mM glutamine, 100 µg ml⁻¹ streptomycin and 100 U ml⁻¹ penicillin G. Cells were split into 100-mm tissue culture plates at 5×10^5 cells per plate and 24–48 h later, 20 µg of each of the four AT-III CAT constructs shown in Fig. 2 were introduced into the cells by calcium phosphate precipitation³⁹. As negative and positive controls, pA₁₀CAT₂ or the SV40 enhancer-containing plasmid pSV2CAT were also used²⁰. Precipitates were kept on the cells for 5 h, after which the cells were washed with MEM and subjected to a 25% glycerol/MEM shock for 1 min; 48 h later, cells were washed in Tris-buffered saline, and scraped from each plate. An aliquot was used for Hirt extracts²³. Hirt supernatants were dot-blotted onto nitrocellulose⁴⁰ and hybridized with a nick-translated pAT1.2 insert (specific activity 3×10^8 d.p.m. µg⁻¹). Hybridizations were carried out overnight at 68 °C in a solution consisting of 6×SSC, 5× Denhardt's solution, 1% SDS, 10 mM phosphate buffer pH 7.0, 1 mM EDTA, 100 µg ml⁻¹ sonicated salmon sperm DNA, 10% dextran sulphate (Pharmacia) and 10^6 d.p.m. ml⁻¹ of nick-translated probe. The remaining cells were subjected to one cycle of freeze-thawing and then sonicated in 100 µl 250 mM Tris-HCl, pH 7.8. In the case of COS-1 cells, 20 µl aliquots of clarified extract were assayed for CAT activity, whereas in all other cases 50 µl was used. The assay system was that described by Gorman *et al.*²⁰, which relies on the conversion of ¹⁴C-chloramphenicol to its acetylated derivatives and their resolution by silica gel TLC.

modest levels above background when introduced into Alexander cells. These experiments suggested that two unrelated genes can be expressed in the same tissues if they share homology in enhancer regions.

It was possible that the effects seen with the AT-III or immunoglobulin gene fragments were the result of the introduction of cryptic promoter elements into the pA₁₀CAT₂ vector. To address this issue, I performed a series of primer extension experiments. An end-labelled CAT-specific *Eco*RI/*Pvu*II restriction fragment was strand-separated and hybridized with total RNA from COS-1 cells that had been transfected with CAT plasmids 48 h previously. The DNA/RNA hybrid was then extended with reverse transcriptase and the size of the product analysed by polyacrylamide gel electrophoresis (Fig. 4). Transcripts initiating at the SV40 early promoter should have extended products 307 bp in length, whereas those originating from upstream sequences should be longer. Transcripts initiated correctly in each of the plasmids tested regardless of whether they contained SV40, AT-III or immunoglobulin upstream sequences.

An understanding of the developmental and/or tissue-specific control of eukaryotic gene expression will ultimately require an appreciation of the various factors whose interactions influence transcription. Specific DNA sequences are known to affect gene transcription, presumably by serving in a manner analogous to classical prokaryotic promoters in allowing for binding of RNA polymerases^{25–29}. The more recent descriptions of enhancers have defined a new class of transcriptional control signals, often with tissue-specific regulatory capacity. That enhancers function irrespective of position and orientation^{1,27–29} has given rise to the notion that, by disrupting chromatin structure, they serve as preferred entry points for RNA polymerases which then scan adjacent DNA sequences until encountering a promoter ele-

ment^{30–32}. Here, I provide evidence for an enhancer element at the 5' end of the human AT-III gene. Its presence was initially inferred on the basis of homologies between the AT-III gene and the *J_κ-C_κ* introns of murine and human immunoglobulin genes which contain tissue-specific enhancers. In addition to their homologies to viral sequences, however, the AT-III and immunoglobulin *J_κ-C_κ* genes share more extensive homologies with one another. That these homologies occur in close physical association with the polyoma virus-like and viral core sequences suggests that they are involved in the tissue-specific regulation of AT-III expression.

Immunoglobulin genes function poorly, if at all, in nonlymphoid cells such as fibroblasts^{3,4}. However, because of the close structural homology between AT-III and *J_κ-C_κ* enhancers, I tested for functional homology by introducing a murine *J_κ-C_κ* enhancer into Alexander hepatoma cells and the AT-III enhancer into myeloma cells. In both cases increased CAT activity was seen although the magnitude of the enhancement was low. This may reflect a suboptimal interaction between the enhancers and tissue-specific factors³³ or the need for additional factors that are absent from the heterologous cells. The *J_κ-C_κ* enhancer showed low activity even in myeloma cells and is consistent with the findings of Picard and Schaffner⁵ who demonstrated that the murine *κ*-chain gene enhancer is only 5% as effective as heavy-chain gene enhancers in promoting heterologous gene transcription.

Extensive homologies among enhancers have not previously been reported. Laimins *et al.*¹⁰ and Weiher *et al.*¹¹ have noted a consensus core sequence (GTGG^{AAA}TTT^G) in several viral enhancer elements but additional sequence homology was not observed. Walker *et al.*⁹ reported that the sequence GTGGAAA was found in fragments with enhancer activity from the 5'-flanking region of human and rat insulin genes although the

Fig. 4 A primer extension analysis of CAT transcripts in COS-1 cells. M, Marker. Primer extended products from cells transfected with: A, pA₁₀CAT₂; B, pA₁₀CAT_{2-K}; C, pATCAT-E3; D, pSV2CAT. **Methods.** Transfections were performed with 20 µg per plate of each plasmid tested (pA₁₀CAT₂, pSV2CAT, pATCAT-E3 and pA₁₀CAT_{2-K}). Cells were collected after 48 h and total RNA was extracted by the guanidine hydrochloride method³⁹. 25 µg RNA was hybridized with 80,000 d.p.m. of a 104-nucleotide-long EcoRI/PvuII strand-separated restriction fragment from the CAT gene which had been labelled at the EcoRI site to specific activity of 2 × 10⁷ d.p.m. µg⁻¹ using polynucleotide kinase and [γ-³²P]ATP (specific activity 7,500 Ci mmol⁻¹; Amersham). Hybridization conditions were: 80% formamide, 280 mM NaCl, 60 mM PIPES, pH 6.8 in 10-µl reactions at 51 °C for 16 h. Hybrids were then phenol-extracted, precipitated and redissolved in 25 µl 70 mM KCl, 10 mM Tris, pH 8.2, 8 mM MgCl₂, 10 mM dithiothreitol, 0.25 mM of each deoxynucleoside triphosphate and 50 U avian myeloblastosis virus reverse transcriptase. After 60 min at 42 °C, the reactions were phenol-extracted, precipitated, redissolved in formamide dye buffer and electrophoresed through an 8% polyacrylamide/8 M urea sequencing gel.

sequence was not required for optimal activity. Therefore, the homology between AT-III and J_κ-C_κ enhancers is striking in view of the minimal relatedness of other enhancers.

In an effort to correlate more precisely the J_κ-C_κ homology with enhancer activity, I have tested a series of deletion plasmids, one of which contains only 177 bp of AT-III sequence, including the immunoglobulin enhancer homology (nucleotide 153-330; Fig. 1). When tested in COS-1 cells, this construct is as active as any of the constructs shown in Fig. 2 (unpublished). Current experiments are focused on the construction of additional deletions to determine whether the same or different sequences are required for full expression in COS and Alexander cells.

The significance of the homologies reported here is not yet clear. It may be that cellular genes contain only a limited number of enhancer elements many of which have fairly extensive homology with each other despite widely different functions of the genes they control. AT-III and light-chain genes might fortuitously represent members of one such subset of enhancers. Alternatively, as B cells are thought to originate in the liver during early embryogenesis^{34,35}, these enhancers might represent common tissue- or stage-specific targets for cellular transcription factors. A distinction between these and other alternatives should be possible when more cellular enhancers have been characterized. In either case, it seems unlikely that the

homologies noted here represent the entire region responsible for tissue specificity. Despite the fact that the AT-III and J_κ-C_κ enhancer elements can function in heterologous cells, it is clear at least for immunoglobulin genes that this is not normally the case³⁶. Other unique cellular factors and/or DNA sequences are likely to be responsible for conferring additional tissue specificity on gene expression.

I thank George Khoury for generously supplying pA₁₀CAT₂ and pSV2CAT and Lloyd Klickstein for the MOPC-41 plasmid. Hunt Potter shared his unpublished results, supplied M12 myeloma cells and introduced me to the technique of electroporation. I also thank Sotirios Karathanasis and Stuart Orkin for advice and support. This work was supported by a National Research Service Award, by a fellowship from the Institute for Pediatric Service of the Johnson & Johnson Baby Products Co. and by NIH Grant ITL 32203.

Cytoplasmic free calcium has been proposed as a regulator of many microtubule-mediated processes, including mitosis. It has been difficult to test this hypothesis because methods for local measurement of free Ca²⁺ in the living cell have not been available. We have used the fluorescent calcium indicator dye Quin-2 (methoxyquinoline-1bis(o-aminophenoxy)ethane-N,N',N',N'-tetraacetic acid), which allows such observations to be made by digital processing of fluorescent images from the light microscope. Here

Fig. 1 Localization of calcium at the mitotic spindle poles of endosperm cells during mitosis. *a*, Bright-field image of a cell in anaphase; *b*, *c*, the same cell observed with 340 and 360 nm excitation after loading with Quin-2; *d*, the I_{340}/I_{360} ratio calculated at each point and redisplayed as an image of the ratio values. Bright areas in *d* correspond to areas of high $[Ca^{2+}]$. Cell wall-free endosperm cells of *Haemanthus Katherinae Baker* were expressed from young ovules onto glass coverslips coated with a thin film of Phytoagar (Gibco), overlain with a thin film of Gelrite (Kelco)²⁷ and perfused with 10 mM citrate buffer, pH 5.2, containing 1 mM $MgCl_2$, 3% glucose and 30 μM Quin-2/AM, for 20 min. Parallel experiments were carried out in medium supplemented with 0.1 mM $CaCl_2$. After loading, the cells were rinsed and incubated in perfusion buffer without the dye for 15 min and cells observed on a Diavert microscope (Leitz) modified for near-ultraviolet excitation¹⁴. Fluorescence-excitation light was passed through narrow band-pass filters centred at 340 and 360 nm, and emitted light was passed through a 500-nm broad bandpass filter (Oriel). (The image-analysis system has been described previously²⁸.) Fluorescent images were obtained with a Dage-MTI model 65 SIT image-intensifier video camera and were recorded on a Panasonic NV8030 videotape recorder with the automatic gain control suppressed. The camera was modified to linearize the intensity response. Images were digitized using a CAT-800 image digitizer (Digital Graphics) housed in a Horizon microcomputer (North Star Computers). The digitizer divides the image into 484×512 picture elements pixels and assigns intensity levels from 0 to 255 using a high speed A to D converter. Six video frames were averaged for each image to reduce noise, and the averaged images were transferred to an LSI 11/23 microcomputer (Digital) with a Gould IP8400 image analyser for further processing. Background values were determined by digitizing images of regions which contained no cells and subtracting these images pointwise from the images of cells. Cell-associated autofluorescence was <10% of the Quin-2 fluorescence with 340 nm excitation. The background-corrected images were then divided pointwise to provide an I_{340}/I_{360} image. The regions corresponding to the cell were identified using a threshold intensity in the 360 nm image, and the I_{340}/I_{360} image of the cell is shown in *d*. The areas of high cytoplasmic Ca^{2+} (high values of I_{340}/I_{360}) correspond to the mitotic spindle poles (arrows). The average cytoplasmic $[Ca^{2+}]$ is ~2-3-fold higher at the spindle poles than in the interchromosomal region. Similar values were observed in 19 other anaphase cells. Scale bar, 100 μm .

we report the application of this technique to the study of local Ca^{2+} concentrations in mitotic endosperm cells of *Haemanthus sp.*, and show that there is transient increase in free Ca^{2+} at the mitotic spindle poles during anaphase. This locally high Ca^{2+} may provide a mechanism for the regional control of microtubules and other cytoskeletal elements during anaphase.

Despite intensive study, the mechanisms of cell division remain poorly understood¹⁻³. Actin filaments⁴ or microtubules⁵ have been suggested as mediators of chromosome movement during mitosis, but the precise role of these cytoskeletal elements is unclear. Several lines of evidence suggest that cytoplasmic Ca^{2+} is important in the regulation of mitosis. Conditions that lower cytoplasmic Ca^{2+} delay the onset of anaphase⁶, and microinjection of Ca^{2+} during metaphase stimulates the transition to anaphase⁷. During anaphase, the spindle pole-to-chromosome microtubules become shorter; in echinoderms these spindle microtubules are very sensitive to Ca^{2+} during anaphase⁸. Calmodulin increases the sensitivity of microtubules to Ca^{2+} both *in vitro*⁹ and *in vivo*¹⁰, and high concentrations of calmodulin have been observed in the mitotic spindle of animal^{11,12} and plant¹³ cells during anaphase. These data suggest a regulatory role for Ca^{2+} in the shortening of the half-spindle, possibly acting through its effect on microtubules.

To determine whether cytoplasmic Ca^{2+} acts as a regulator of mitosis, accurate measurements of changes in Ca^{2+} must be made at each stage of mitosis. Because of the difficulty in obtaining tightly synchronized populations of dividing cells, such measurements must be made on individual cells assigned to a stage of mitosis by direct observation at the time of measure-

ment. Recently, a method has been developed for the measurement of cytoplasmic Ca^{2+} in individual cells using the fluorescent dye Quin-2 (ref. 14). The method is based on the observation that Quin-2 fluorescence excited at 340 nm is highly Ca^{2+} dependent, whereas the Quin-2 fluorescence excited at 360 nm is independent of $[Ca^{2+}]$ (ref. 15). Thus, the ratio of the two intensities (I_{340}/I_{360}) is dependent on Ca^{2+} but independent of changes in dye distribution resulting from changes in cell shape and thickness during mitosis. We have used this method to measure the average cytoplasmic $[Ca^{2+}]$ in rat kangaroo epithelial cells. During mitosis, the average cytoplasmic $[Ca^{2+}]$ was half the interphase value (28 against 53 nm), with no statistically significant variations observed among the mitotic stages¹⁶. These measurements of average $[Ca^{2+}]$ indicated that cytoplasmic Ca^{2+} does change during mitosis, but no evidence was obtained concerning local changes in $[Ca^{2+}]$ which might be required for directed motion. Here we report measurements of local $[Ca^{2+}]$ in mitotic cells.

The intensity ratio method is well suited for measuring local $[Ca^{2+}]$ by image digitization and analysis (see Fig. 1 legend). The intensity values provide a two-dimensional representation of cytoplasmic $[Ca^{2+}]$ within the cell. The horizontal resolution of the method is limited by the thickness of the cell and the optical properties of the microscope. Although the method has been developed using Quin-2, it is suitable for use with dyes of higher quantum efficiency and more favourable spectroscopic qualities, such as Fura-2 (ref. 17).

We used endosperm cells of the African blood lily, *Haemanthus Katherinae Baker*. The cells are extremely large, facilitating

observation of gradients, and their mitosis has been studied extensively¹⁸. The acetoxymethylester of Quin 2 (Quin-2/AM) was added to the cells (Fig. 1), which trapped Quin-2 by conversion of the ester to the tetracarboxylic acid. Cell-associated fluorescence increased ~10-fold with 340 nm excitation and 492 nm emission. During loading, the chromosome movement seems to stop. However, this inhibition is found to persist only for 5 min after removal of Quin-2/AM, after which anaphase progresses normally. For cytoplasmic Ca^{2+} measurements, the cells were incubated in buffer lacking Quin-2/AM for at least 15 min before the observation. Based on observation of several hundred cells, the loading procedure does not block the progression of cells from metaphase to telophase.

Criteria for selection of cells for measurements included: (1) flatness; (2) low refractive index; (3) no starch grains; (4) no debris or other cells covering the cell of interest; (5) observable chromosome movement in anaphase cells. Cells were observed, and I_{340}/I_{360} ratio images obtained, at all stages of mitosis. In interphase cells, the cytoplasmic $[\text{Ca}^{2+}]$ is fairly uniform. However, the cytoplasm of the ratio image is 1.6 times brighter than the nucleus. It is not clear that this can be attributed to a lower $[\text{Ca}^{2+}]$ in the nucleus as the behaviour of Quin-2 in the nuclear environment cannot be readily predicted. It is unlikely that the lower value results from exclusion of dye from the nucleus; when cells are labelled in prometaphase and allowed to proceed through telophase, the newly formed daughter nuclei also have a lower I_{340}/I_{360} fluorescence ratio. The prometaphase cell also exhibits a low ratio in the area of the nucleus despite the breakdown of the nuclear membrane. Cytoplasmic free Ca^{2+} is still evenly distributed. The metaphase cell does not show any readily observed inhomogeneity of $[\text{Ca}^{2+}]$ either along the spindle itself or outside the spindle area.

In anaphase, there is a marked departure from the homogeneous distribution of free Ca^{2+} seen in the previous stages. In 24 out of 28 anaphase cells examined, we observed regions of higher free Ca^{2+} near the mitotic spindle poles (Fig. 1). This distribution is observed in cells in early, mid and late anaphase, indicating that the gradient lasts from 30 to 45 min. Quantitative analysis in 20 of these cells indicated that the I_{340}/I_{360} ratio at the polar region was 1.67 ± 0.08 (s.e.m.) $\times$ higher than the ratio in the region between the chromosomes. This contrasts sharply with metaphase where the I_{340}/I_{360} ratio at the poles was only 1.1 ± 0.04 higher than at the metaphase plate. Eight anaphase cells were excluded from quantitative analysis for the following reasons: (1) Four cells, which did not demonstrate localization at the poles, were not flat. As the thickness of the cell becomes greater, contributions from out-of-focus parts of the cell may interfere with local measurements of intracellular Ca^{2+} ; (2) Four other cells which demonstrated localization of Ca^{2+} at the spindle poles were excluded because the Quin-2 fluorescence was either too high or too low for accurate measurements. In telophase, the cytoplasmic free Ca^{2+} distribution is once again more homogeneous, with lower I_{340}/I_{360} in the daughter nuclei.

To investigate the possibility that in cells loaded with Quin-2, citrate, a Ca^{2+} chelator, caused changes in cytoplasmic distribution, we compared cells incubated in low Ca^{2+} and Ca^{2+} supplemented medium (0.1 mM). In all stages of mitosis the pattern for that stage when incubated in high Ca^{2+} was not significantly different from that of the cells incubated in low Ca^{2+} medium. Sixteen anaphase cells were observed in low Ca^{2+} medium and the intensity ratio at the poles to that of the mid-zone was 1.66 ± 0.07 . Four additional anaphase cells were observed in high Ca^{2+} , and the ratio of Quin-2 fluorescence at the poles to that of the mid-zone (1.68 ± 0.27) was not significantly different from that of the low Ca^{2+} medium. In parallel experiments, whole-cell values of cytosolic Ca^{2+} in cells incubated in high Ca^{2+} medium (52 ± 7 nM, $n=4$) were similar to cells incubated in low Ca^{2+} medium (47 ± 4 nM, $n=11$). These observations

support the existence of large stores of intracellular Ca^{2+} and the existence of efficient Ca^{2+} homeostatic mechanisms in *Haemaphysalis endosperm*.

Our data indicate that cytoplasmic Ca^{2+} is elevated in the cytoplasm near the spindle poles during anaphase. Membrane-limited organelles have been observed along the mitotic spindle^{19,20} which may sequester Ca^{2+} , presumably to release it during anaphase^{21,22}. Our data show that the rate of release into the cytoplasm (and removal elsewhere) is sufficient to maintain a twofold gradient of $[\text{Ca}^{2+}]$ across the cell. Higher concentrations are probably attained near the sites of release, but our measuring procedure averages I_{340}/I_{360} throughout the thickness of the cell. The effect of Quin-2 itself on the gradient is not known, but Quin-2 probably reduces the magnitude of the $[\text{Ca}^{2+}]$ gradient by acting as a Ca^{2+} chelator.

Although the effect of local Ca^{2+} gradients during anaphase is not yet known, certain hypotheses can be suggested. Binding of Ca^{2+} reduces the mobility of calmodulin in the cell¹⁰, probably by causing binding of Ca^{2+} -calmodulin to relatively immobile proteins. Thus, locally high Ca^{2+} may trap calmodulin in the mitotic spindle, leading to the observed inhomogeneous distribution of calmodulin during anaphase¹¹⁻¹³. Ca^{2+} -calmodulin causes disassembly of microtubules^{9,10}, and the high concentrations of Ca^{2+} and calmodulin would be expected to cause the shortening of the kinetochore fibres as the chromosomes approach the poles. Of course, Ca^{2+} is also a regulator of actin-based force-generating systems²³, and locally high Ca^{2+} may activate such a system to provide a motile force.

Transient intracellular Ca^{2+} gradients have been reported for several phenomena, ranging from nerve-cell depolarization²⁴ to sea urchin egg activation²⁵. We have shown that long-lasting Ca^{2+} gradients exist in dividing cells during anaphase which may provide a mechanism for local control of motility within the cells. For example, microtubules could be disassembled by Ca^{2+} calmodulin in one region (for example, the mitotic spindle) while microtubule assembly proceeds elsewhere (for example, the interpolar microtubules)²⁶. These studies are now being extended to other cell types, particularly mammalian cells.

New York
Tokyo

Biology and Fertility of Soils, appearing in 1985, will report on new developments in fundamental and applied aspects of biology and productivity of soils. Edited by a board of respected scientists with expertise in soil biology, soil fertility, soil hygiene and soil biotechnology, the journal will rapidly publish original papers, reviews, and short communications. A hallmark of the journal will be its reports on techniques and methods that evaluate processes, biogeochemical interactions and ecological stresses. **Biology and Fertility of Soils** will also issue special numbers on relevant subjects, calling for comprehensive reviews and reappraisals of concepts.

Environmental threats, such as acid rain and heavy metals, underscore the necessity of a forum for research aimed at broadening the understanding of biological functions, processes, and interactions in soils.

Biology and Fertility of Soils will be particularly useful for soil, plant, and environmental scientists concerned with the increasing demands of agriculture, deforestation, and industrialization.

From the contents of Volume 1 Number 1

- L. L. Goodroad, D. R. Keeney:** Site of nitrous oxide production in field soils
S. I. Ghabbour, J. P. C. Da Fonseca, W. Z. A. Mikhail, H. Shakir: Differentiation of oil fauna in desert agriculture of the Mariut region
F. Ganry, H. G. Diem, J. Wey, Y. R. Dommergues: Inoculation with *Glomus mosseae* improves N_2 fixation by field-grown soybeans
P. Nannipieri, B. Ceccanti, D. Bianchi, M. Bonmati: Fractionation of hydrolase-humus complexes by gel chromatography
M. N. I. Abou Seada, J. C. G. Ottow: Effect of increasing oxygen concentration on total denitrification and nitrous oxide release from soil by different bacteria
A. J. Reinecke, J. M. Venter: Influence of dieldrin on the reproduction of the earthworm *Eisenia fetida* (Oligochaeta)
R. K. Reid, C. P. P. Reid, P. J. Szaniszlo: Effects of synthetic and microbially produced chelates on the diffusion of iron and phosphorus to a simulated root in soil
K. Mengel, D. Steffens: Potassium uptake of rye-grass (*Lolium perenne*) and red clover (*Trifolium pratense*) as related to root parameters

Manuscripts may be submitted for review to any of the editors listed at left. For a copy of instructions to authors, check the appropriate box on the order form and mail it to the Springer-Verlag office nearest you.

UNIVERSITY OF ST ANDREW'S

Department of Anatomy and
Experimental Pathology

CELL/DEVELOPMENTAL BIOLOGIST

Applications are invited for a post doctoral research assistant to work with Dr J McLachlan on the control of cell division in embryonic limb development. This appointment is funded by the Medical Research Council and is for a period of 2 years from October 1st 1985. Experience in tissue culture techniques is desirable.

Starting salary within range £7,520 — £8,920 per annum plus USS

Applications with the names of 3 referees should be sent by 13th September 1985 to Dr J C McLachlan, Department of Anatomy and Experimental Pathology, The University, St Andrew's, Fife KY16 9TS

(7481)A

UNIVERSITY OF ABERDEEN

DEPARTMENT OF BIO-MEDICAL
PHYSICS AND BIO-ENGINEERING
PHYSICIST/ANIMAL
SCIENTIST

Applications are invited for the above post to work at Ayr and Aberdeen in active research team using NMR (with imaging) to study lactation, foetal development and body composition of farm animals. Applicants preferably post-doctoral or with relevant research experience. The appointment is available for a three year period.

Salary within range £7,520 — £10,330 per annum, on the Grade 1A Scale for Other Related Staff, with appropriate placing (scale under review).

Further particulars and application forms from The Secretary, The University, Aberdeen, with whom applications (2 copies) should be lodged by 20 September 1985. (Ref No EL/013). (7497)A

UNIVERSITY OF ABERDEEN

DEPARTMENT OF BIO-MEDICAL
PHYSICS AND BIO-ENGINEERING
PHYSICIST/COMPUTER
SOFTWARE ENGINEER

Applications are invited for the above post in an internationally known NMR imaging team to provide large analysis and computer control data collection in association with study of NMR (with imaging) in farm animals. Applicants preferably post-doctoral or with relevant research experience. The appointment is available for a three year period.

Salary within range £7,520 — £10,330 per annum, on the Grade 1A Scale for Other Related Staff, with appropriate placing (scale under review).

Further particulars and application forms from The Secretary, The University, Aberdeen, with whom applications (2 copies) should be lodged by 20 September 1985. (Ref No EL/012). (7496)A

UNIVERSITY OF EXETER

DEPARTMENT OF PHYSICS
Low Temperature Group

A POSTDOCTORAL RESEARCH ASSISTANT

is required to work on an SERC funded project investigating several aspects of the recently discovered Quantum Evaporation effect. This is the analogue of the photoelectric effect with phonons and atoms which can be achieved in liquid ⁴He at temperatures around 0.1 K.

The appointment will begin 1 October 1985 or soon after, with a starting salary in the range £7,520 — £8,450 per annum. It will run for two years.

Suitable qualified physicists with low temperature experience should apply to Professor A F G Wyatt, Department of Physics, University of Exeter by 9 September 1985 giving the names and addresses of three referees. (7499)A

Research Molecular Biologist and Microbiologist Beckenham, Kent

The Wellcome Research Laboratories are the main research centre for The Wellcome Foundation Ltd, an international group of pharmaceutical and chemical companies with headquarters in the United Kingdom and an annual turnover in excess of £800m.

Within the Biomedical Research Division (Director, Dr J. G. Howard, FRS) the Department of Experimental Immunobiology (Head, Dr F.Y. Llew) undertakes research concerned with the regulation of immunological responses in relation to infectious diseases and mediator functions.

In order to strengthen our current programmes we are now seeking to expand our experienced research team with the following appointments—

Senior Molecular Biologist not less than £11,400

To initiate and direct innovative programmes of work, and collaborate with senior scientists of various disciplines in a range of existing and new research activities. The successful candidate will have at least three years' post doctoral research experience involving the application of expertise in molecular cloning and expression of immunologically relevant materials. He/She will have a record of success and originality in the field of Molecular Biology. Ref. WRL 357

Research Microbiologist £9,400 — £12,500

To contribute to existing programmes aimed at the development of novel methods for the control of clinical bacterial infections. Applicants must possess a PhD in microbiology and extensive experience within the fields of bacteriology and carbohydrate biochemistry. This appointment will initially be of three years' duration with possibility of confirmation to an established position. Ref WRL 358

We offer competitive salaries for both positions, based upon experience. Excellent benefits include assistance with relocation, as appropriate.

Please write with full personal and career details, quoting the appropriate reference number to: Dr. H. Avshu, Personnel Officer, The Wellcome Research Laboratories, Langley Court, Beckenham, Kent BR3 3BS.

... NN

pathologist drug safety evaluation

An opportunity exists in the Pathology Group at SEARLE RESEARCH and DEVELOPMENT Center located in the South of France.

The candidate should have a D.V.M., M.D. or Ph.D degree in Pathology and at least five years experience (preferably in the pharmaceutical industry) in veterinary pathology.

The successful candidate will act as pathologist (slide reading and interpretation) on preclinical safety studies and will be involved in pathology research programs.

SEARLE R & D offers excellent laboratory facilities, competitive salaries, benefits and paid relocation. The Center is located in a particularly attractive part of France between Nice and Cannes, and is a part of G.D. SEARLE and Co., an international pharmaceutical company.

Applications with a full C.V. including current salary should be addressed to

Mr G. du Parc, Personnel Manager,
SEARLE Recherche et Développement
Sophia Antipolis - B.P. 23
06561 VALBONNE Cedex, FRANCE (Ref. N.7)

SEARLE

(W2049)A

MRC CELLULAR IMMUNOLOGY UNIT Associated with the SIR WILLIAM DUNN SCHOOL OF PATHOLOGY University of Oxford CELLULAR IMMUNOLOGIST

Applications are invited for a short-term non-clinical scientific post at postdoctoral level tenable for 3 years in the first instance.

The successful candidate would have the support of a technical assistant and other scientific colleagues and would be required to initiate *in vitro* studies on lymphocyte functions with a particular view to elucidating the role of cell surface molecules. One area of interest could be lymphocyte endothelium interactions but other topics could also be considered.

The appointment could begin at any time from October 1, 1985 onward. Remuneration will be at an appropriate point on the Research Support 1A scale £7,520 — £12,150 (under review). Applications should be sent to Doctor A.F. Williams, MRC Cellular Immunology Unit, Sir William Dunn School of Pathology, University of Oxford, South Parks Road, Oxford OX1 3RE (Telephone Oxford 57321) (7505)A

A PROFESSORSHIP (C2) IN BIOCHEMISTRY

at the Faculty of Chemistry and Pharmacy is to be filled by January 1st, 1986

The successful candidate is expected to partake in research and teaching. His research activities should concentrate in the field of biophysical chemistry. It is required that applicants have completed and have qualified as a lecturer in biochemistry.

Applicant should not exceed the age of 40 years at the time of their appointment.

Applications should be sent to the Dean of the Faculty of Chemistry and Pharmacy, Universitätshauptgebäude, Geschwister-Scholl-Platz 1, D — 8000 München 22 and accompanied by the usual documents (curriculum vitae, certificates, list of publications). (W2158)A

UNIVERSITY OF QUEENSLAND LECTURER (fixed term) — ENTOMOLOGY

Must have a PhD and sound training in entomology. As well as normal duties, job will entail supervision of postgraduate students working for Masters and PhD degrees especially in agricultural entomology.

Salary per annum: \$A26,236 — \$A34,467

Closing date: 10th October, 1985. Ref. 33685.

Additional information and applications forms are available from the Secretary-General, Association of Commonwealth Universities, 36 Gordon Square, London WC1H 0PF.

The University of Queensland is an Equal Opportunity Employer. (W2163)A

THE ANIMAL VIRUS RESEARCH INSTITUTE MOLECULAR BIOLOGIST

Applications are invited for the post of molecular biologist to work on analysis of the DNA genome of capripox virus and its development for use as a eukaryotic vector system. The post is funded by the Overseas Development Administration for four years. The successful candidate will work with Dr Donald Black in the Division of Molecular Biology. He/she should have a PhD degree in Biochemistry or a related subject; experience with molecular cloning and eukaryotic gene analysis would be an advantage.

The salary will be in the scale £7,788 to £10,541 (Higher Scientific Officer Grade). Sick leave and non-contributory superannuation schemes, 22 days annual leave. Accommodation may be available. The AVRI is an equal opportunity employer.

Application to include a curriculum vitae and the names of two referees should be sent as soon as possible to the Secretary, The Animal Virus Research Institute, Ash Road, Pirbright, Woking, Surrey, GU24 0NF Tel 0483 232441. (7498)A

CELL BIOLOGIST UNIVERSITY OF ALABAMA AT BIRMINGHAM

Applications are invited for the position of Assistant Professor (tenure-track) in the Department of Cell Biology and Anatomy, University of Alabama at Birmingham. Candidates must have post-doctoral experience in Cell or Molecular Biology with research interest in one or more of the following areas: (a) cytoskeleton and motility, (b) growth control and cell division, (c) cell structure and function, or (d) neuronal growth and development. Other criteria for appointment will include (1) strongly motivated teaching interests and skills as indicated by outstanding communicative ability and command of subject, (2) highly creative and competitive research potential and (3) interest and potential to contribute to faculty, university and community growth.

Salary and benefits competitive. Submit current curriculum vitae including three letters of reference by October 1, 1985 to: Dr. B. R. Brinkley, Professor and Chairman, Department of Cell Biology and Anatomy, Schools of Medicine and Dentistry, University of Alabama at Birmingham, Birmingham, Alabama 35294.

An Equal Opportunity/Affirmative Action Employer. (NW175)A

UNIVERSITÄT STUTTART

Zentrum Bioverfahrenstechnik

Am Standort Stuttgart wird im Verbund zwischen der Universität Stuttgart und der Fraunhofer-Gesellschaft ein Schwerpunkt Bioverfahrenstechnik aufgebaut.

Im Rahmen dieses Schwerpunktes wird an der Universität Stuttgart ein gut ausgestatteter Kernbereich, bestehend aus den Disziplinen Mikrobiologie, Genetik, Biochemie und Bioverfahrenstechnik eingerichtet, in dem in enger Kooperation Projekte gemeinsam ausgewählt und betrieben werden sollen.

Zu besetzen sind folgende Stellen:

In der Fakultät Chemie eine

C-4 Professur für Technische Biochemie

Der Bewerber soll in der Lage sein, das Fach Biochemie in der Lehre abzudecken. Der Schwerpunkt der Lehre ist die technische Anwendung der Biochemie. Der Bewerber soll auch Ausbildungsfunktionen für Biologen und Verfahrenstechniker übernehmen.

In der Fakultät Verfahrenstechnik eine

C-4 Professur für Bioverfahrenstechnik

Der Bewerber soll hervorragend ausgewiesen sein und über eigene Erfahrungen auf den Gebieten der Reaktionskinetik, der mathematischen Modellierung, der experimentellen Untersuchung und Analyse bioverfahrenstechnischer Prozesse verfügen. Vorausgesetzt werden ferner Aufgeschlossenheit und Erfahrung bezüglich ingenieurtechnischer Problemstellungen und — Lösungen in der Bioverfahrenstechnik. Industriearbeit wird begrüßt.

Bewerbungen mit Lebenslauf, Schriftenverzeichnis und Angaben über die bisherige Tätigkeit werden bis zum 15. Oktober 1985 erbeten. Sie sind für die erstgenannte Stelle zu richten an den Dekan der Fakultät Chemie, Pfaffenwaldring 55, D — 7000 Stuttgart 80, für die letztgenannte Stelle an den Dekan der Fakultät Verfahrenstechnik, Pfaffenwaldring 9, D — 7000 Stuttgart. (W2160)A

POSTDOCTORAL POSITION IN SOLID STATE PHYSICS WITH POSITIVE MUONS ETH ZÜRICH/SWITZERLAND

An open postdoctoral position has become available in the group for Muon Spin Rotation (μ SR) Spectroscopy at the *Institute for Intermediate Energy Physics of the ETH Zurich (IMP)*. The research program of this group involves the study of magnetic and electronic properties of metals, metal alloys and metal hydrides, ranging from simple metals to heavy Fermion systems.

An experimental physicist (Ph.D.) is sought, who is particularly inclined towards experimental work and who is willing to work in a team of 4-5 physicists and other outside collaborators. A strong solid state background or experience in NMR and related methods would be of advantage. The interdisciplinary character of the μ SR-research requires an aptitude in the use and handling of quite different equipment in a variety of measuring tasks (modern fast counting electronics, on-line computing, precision measurements of magnetic fields (NMR), cryostats (including a ^3He - ^4He dilution refrigerator), ovens, temperature measurements, physical characterization of samples e.g. by X-ray and neutron diffraction).

The appointment will be initially for three years with the possibility of extension for another three years. Additional information can be obtained from Dr A. Schenk (Telephone 056/99 32 63).

Applications, containing curriculum vitae, list of publications and references should be sent to:

SIN, Personnel Division
CH-5234 Villigen/Switzerland
Code IMP/31E

Directorate of Planning Services (Minerals Division) Department of the Environment - London

Geologist

The Minerals Division of the Directorate of Planning Services is responsible for the Department's policy and professional advice on minerals and this post will deal with all non-energy minerals.

A major part of the work relates to aggregates. You will represent the Department on a number of Aggregate Working Parties, which are made up of county planning officers and representatives of industry, and act as technical secretary at a national level. You will be concerned with geological and minerals planning research carried out in support of the Department's policy functions and you will provide professional and technical advice for Ministers, senior civil servants and colleagues.

You must have a good honours degree in an appropriate scientific subject and at least 4 years' relevant postgraduate experience.

Appointment as Senior Scientific Officer £11,135 - £14,015 (including £1365 Inner London Weighting) with starting salary according to qualifications and experience.

RELOCATION EXPENSES MAY BE AVAILABLE

For further details and an application form (to be returned by 20 September 1985) write to: Department of the Environment, Room 459, Lambeth Bridge House, London SE1 7SB or telephone 01-211 6466. Please quote ref: SA/39/H.

CORPORATE BIOSCIENCE GROUP PLANT MOLECULAR BIOLOGY GROUP

Due to expansion of existing programmes the Plant Molecular Biology Group at ICI's Runcorn Laboratories have a staff vacancy for a

SCIENTIST with a strong background in PLANT TISSUE CULTURE

To join a team analysing plant gene expression using recombinant gene technology and plant transformation. Applicants should have a good Honours degree in one of the biological sciences, and at least two years of practical experience in plant tissue culture. Knowledge of plant transformation using Agrobacterium vectors would be a definite advantage.

The job is available immediately. Initially, the position will be held at Runcorn but within the next three years the group will transfer to a new Exploratory Plant Sciences Laboratory at ICI Plant Protection Division in Berkshire. Further information can be obtained from Dr. W. Schuch at Runcorn (0928) 511253.

The initial salary will depend on qualifications and experience, but will be in the range of £8,300-£9,300. Applications including names of two referees quoting ref. PMBG to:

Mr. R. Neale,
ICI Corporate Bioscience Group,
IMPERIAL CHEMICAL INDUSTRIES PLC.,
PO BOX 11, The Heath, Runcorn, Cheshire.

Closing date 19th September 1985

UNIVERSITY OF KENT**AT CANTERBURY ■■■■
BIOLOGICAL LABORATORY
POSTDOCTORAL
RESEARCH FELLOW**

Applications are invited for a Post-doctoral Research Fellow to join the new University of Kent — Laboratory of the Government Chemist BIOTRANS project. The post, initially for one year with the possibility of an extension for a further two years, is to investigate the biotransformation of halogenated xenobiotic compounds in the laboratories of Professor A T Bull and Dr D J Hardman. Experience in microbial physiology, biochemistry or biocatalyst immobilization would be an advantage. The salary will be £7520 – £12150 (under review) on the Grade 1A scale. Apply by letter with full curriculum vitae citing the names and addresses of two referees to the Assistant Registrar, Faculty of Natural Sciences, The Registry, University of Kent, CANTERBURY, Kent CT2 7NZ by 20 September 1985. Please quote ref A52/85/N (7511)A

**RESEARCH
ASSOCIATE
POSITIONS**

Positions are now available to study the mechanisms by which peptides obtained from eggs stimulate and/or attract spermatozoa using the sea urchin as a model system.

Positions are also available to pursue similar studies in higher animals including the mammal. Stipends will be commensurate with experience.

Please send curriculum vitae and references to: Dr David L. Garbers, Howard Hughes Medical Institute at Vanderbilt University Medical Center, 711 Light Hall, Nashville, TN 37232. (NW182)A

Biotechnologists

Beecham Pharmaceuticals is a highly successful company with an international reputation for excellence in research and development. Fermentation and enzymatic processes are used in the manufacture of several of the company's products. Improving the efficiency of these processes in order to reduce manufacturing costs is vital for success in today's highly competitive environment and requires an innovative approach, including the application of genetic engineering. These

functions are carried out by multi-disciplinary teams in the Fermentation Development Department which contains well-equipped laboratories and pilot plants.

The following job opportunities have arisen for which the successful candidates must demonstrate a strong motivation in applying their scientific discipline towards industrially-orientated objectives.

Fermentation Pilot Plant Support Laboratory

A Biochemist is required for the Fermentation Pilot Plant Technical Support Section to organise the work of a group of technical assistants. The work will involve participation in planning and monitoring experimental fermentations including data collection and processing as well as directing laboratory

investigations associated with these fermentations.

Applicants should possess a good honours degree in Biochemistry, preferably with additional experience in the study of fermentation processes.

Minifermenter Unit

A vacancy has also arisen in our Minifermenter Unit for a Development Scientist. Working in a well-equipped department, the successful candidate will contribute to the development of existing and new fermentation processes and will be closely involved in the use of modern

instrumentation and computers for data logging and process control. Candidates should have a good honours degree; previous experience of fermentation and computers would be useful, but not essential.

The Beecham Group offer attractive starting salaries backed by excellent conditions of service, including a non-contributory pension and life assurance scheme. Worthing is situated in a pleasant coastal area with many amenities and easy access to the surrounding countryside. Assistance with relocation expenses will be given if appropriate.

Please write or telephone, indicating which job you wish to apply for to: Mr R P Reynolds, Senior Personnel Officer, Employee Relations Department, Beecham Pharmaceuticals, Clarendon Road, Worthing, West Sussex BN14 8QH. Tel: Worthing (0903) 39900, ext 332.

Beecham Pharmaceuticals

**CELL BIOLOGY
AND PHYSIOLOGY
WASHINGTON UNIVERSITY SCHOOL
OF MEDICINE
ST LOUIS, MISSOURI**

The Department of Cell Biology and Physiology, Washington University School of Medicine, St Louis, Missouri, is expanding its commitment to research in the following areas: (i) membrane protein function and biogenesis; (ii) assembly, function, and movement of intracellular organelles; (iii) cell motility and contractility; and (iv) cell-cell and cell-matrix interactions. Individuals who employ novel biophysical and recombinant DNA methodologies are especially encouraged to apply. Tenure track positions are available for successful candidates who will be expected to develop an independent research program and to participate in the training of medical and graduate students.

Please submit curriculum vitae and the names of three references to: Dr Philip Stahl, Department of Cell Biology and Physiology, Washington University School of Medicine, 660 South Euclid Avenue, St Louis, MO 63110.

An Affirmative Action / Equal Opportunity Employer.

**BIOCHEMIST/
MOLECULAR BIOLOGIST**

The Department of Biochemistry and Biophysics is seeking applications for two Assistant or Associate Professorships. These are 12 month, tenure track positions jointly funded by the College of Agriculture and the Texas Agricultural Experiment Station. Outstanding individuals having research interests dealing with the molecular aspects of regulation, structure, mechanism or function in microbial, animal or plant systems are sought. In addition to research, participation in the department graduate and undergraduate teaching programs will be required. A terminal degree in either biochemistry or a related field plus appropriate postdoctoral experience is required.

Applicants should send a curriculum vitae, list of publications, a brief description of current and future research directions, and names of three references to:

Dr. E. G. Sander, Head
Department of Biochemistry and Biophysics
Texas A&M University
College Station, TX 77840-2128

Applications will be accepted until October 15, 1985, or until suitable candidates are found.

The Texas A&M University System is an Affirmative Action/Equal Opportunity

UNIVERSITÄT STUTT GART

Zentrum Bioverfahrenstechnik

Am Standort Stuttgart wird im Verbund zwischen der Universität Stuttgart und der Fraunhofer-Gesellschaft ein Schwerpunkt Bioverfahrenstechnik aufgebaut.

Im Rahmen dieses Schwerpunktes wird an der Universität Stuttgart ein gut ausgestatteter Kernbereich bestehend aus den Disziplinen Mikrobiologie, Genetik, Biochemie und Bioverfahrenstechnik eingerichtet, in dem in enger Kooperation Projekte gemeinsam ausgewählt und betrieben werden sollen.

Als eine der zu besetzenden Stellen ist in der Fakultät Geodätische Biowissenschaften eine

C4 — Professur für Industrielle Genetik

zu besetzen.

In der Lehre ist die Grund- und Fortgeschrittenenausbildung im Fach Mikrobielle Genetik und Gentechnologie für Studenten der Biologie, Biochemie und Bioverfahrenstechnik zu erbringen.

Bewerbungen mit Lebenslauf, Schriftenverzeichnis und Angaben über die bisherige Tätigkeit sind bis zum 15. Oktober 1985 an den Dekan der Fakultät für Geo- und Biowissenschaften, Biologisches Institut, Ulmer Str. 227, D 7000 Stuttgart 60 zu richten. (W2161)A

NORDITA COPENHAGEN

ASSISTANT PROFESSOR IN THEORETICAL NUCLEAR PHYSICS

NORDITA, the Nordic theoretical physics institute, located at the Niels Bohr Institute of Copenhagen University, has an opening starting in January 1986, or later if that is more convenient, for an assistant professor in theoretical nuclear physics. Nuclear physics will be interpreted in the broadest terms including the areas of nuclear structure, intermediate energy physics, the effects of quarks and other degrees of freedom in nuclear phenomena, as well as the phenomena to be expected in ultra relativistic collisions of heavy nuclei.

The successful applicant is expected to guide fellows at roughly the postdoctoral level and to interact with colleagues at NORDITA and elsewhere in the Nordic countries. The position provides excellent opportunities to pursue original research and to have contact with a wide range of developments in theoretical physics. There are good facilities for travelling to other institutes and to meetings outside the Nordic countries; and the assistant professor will be encouraged to invite guest scientists to NORDITA.

The initial appointment will be for three years, with the possibility of renewal up to a total of six years. The annual salary will be in the range of 190,000–270,000 Danish Kroner depending on experience.

Those interested in the appointment should send curriculum vitae, a list of publications and the names of three referees before 1 November 1985 to the Director, Nordita, Blegdamsvej 17, DK-2100 Copenhagen Ø, Denmark. There is no restriction on the nationality of the applicant. Those wishing to recommend suitable candidates are urged to contact the Director. (W2151)A

METEOROLOGICAL ANALYST BUREAU OF METEOROLOGY RESEARCH CENTRE Melbourne Australia

SALARY \$A26,056 — \$A28,831

Applications for the position of Meteorological Analyst in the recently created Bureau of Meteorology Research Centre (BMRC) are invited from Scientists with research experience in the field of atmospheric modelling to conduct research in the Medium Range Prediction Group. The successful applicant will be expected to:

- (i) develop procedures to diagnose and evaluate numerical model performance; and
- (ii) identify the physical and dynamical mechanisms associated with errors in numerical forecasting models.

Qualifications

An appropriate degree or diploma in Science or equivalent qualifications. Research experience in the fields of atmospheric modelling and computational physics is desired. Possession of a PhD is highly desirable.

Conditions

The successful applicant will be offered an initial fixed term of engagement for a period of three years. Re-engagement for a further period may be available. Conditions of service include four weeks annual recreation leave, cumulative sick leave, three months long service leave after ten years, an annual leave loading and a comprehensive superannuation scheme. Assistance with removal costs will also be available, if required.

Enquiries may be directed to Dr W. Bourke, Senior Principle Research Scientist (BMRC). Telephone: Melbourne (03) 669 4425. Applications stating full personal and professional details and the names of referees should be forwarded to:

**DIRECTOR OF METEOROLOGY
GPO BOX 1289K
MELBOURNE, VICTORIA 3001
AUSTRALIA**

(W2156)A

UNIVERSITY OF MARYLAND SCHOOL OF MEDICINE

Department of Biological Chemistry

POSTDOCTORAL RESEARCH ASSOCIATE

Position is available for three years from September 1, 1985 to study molecular mechanisms of hormonal regulation of heart Ca^{2+} channels. Research involves receptor binding, protein phosphorylation, Ca^{2+} flux, and electrophysiological studies using cultured heart cells. Background in biochemistry, cell biology, or pharmacology is essential with a commitment to training in biochemical approaches. Salary negotiable.

Applications along with CV and the names of three references should be sent to: Dr. Terry B. Rogers, Dept. of Biochemistry, Univ. of Maryland, School of Medicine, 660 W. Redwood St., Baltimore, MD, 21201.

Equal Opportunity Employer.

(NW187)A

Director, Hopkins Marine Station Department of Biological Sciences STANFORD UNIVERSITY

The Department of Biological Sciences of Stanford University seeks a distinguished biologist to serve as professor and director of the Hopkins Marine Station. The director will hold an endowed chair and will be appointed as Professor of Biological Sciences at Stanford University. The director will be expected to provide scientific leadership with an established, vigorous research program in the area of cell, developmental, molecular, environmental, organismal, and/or population biology. The director's responsibilities include the provision of leadership for faculty expansion and for development of innovative teaching programs at the Station.

Applicants should submit a curriculum vitae and the names of three persons willing to serve as reference to:

**Chairman, HMS Search Committee
Department of Biological Sciences
Stanford University
Stanford, CA 94305**

Stanford is an equal opportunity employer.

(NW133)A

SUNDERLAND AND TEESIDE POLYTECHNICS

NORTH EAST BIOTECHNOLOGY CENTRE POSTGRADUATE RESEARCH ASSISTANT IN MOLECULAR GENETICS

Salary: £5,181-£5,910 (under review)

The North East Biotechnology Centre (NEBC) is a National Centre for Biotechnology based at Sunderland and Teesside Polytechnics. The Centre has a vacancy in the Biology Dept. at Sunderland Polytechnic for a Research Assistant to undertake a research project involving a molecular analysis of transposable element systems in maize. Post suitable for graduates in biochemistry, molecular biology or botany and experience with recombinant DNA techniques would be an advantage. Candidate will be expected to register for a higher degree.

An application form and further particulars obtained from the Personnel Officer, Sunderland Polytechnic, Langham Tower, Ryhope Road, Sunderland, SR2 7EE, or telephone (0783) 76231 Ext 11.

Closing date: 12 September 1985

(7506)A

RESEARCH ASSOCIATE IN PROTEIN CRYSTALLOGRAPHY

Postdoctoral or more senior position available for protein crystallographer to work on the structure determination of fibrinogen (principal fibrous protein in blood clotting) and troponin/tropomyosin (protein switch in muscle contraction). The Structural Biology Laboratory at Brandeis has exceptional facilities for X-ray diffraction, electron microscopy and image processing, and provides access to a broad range of problems and techniques in macromolecular structure determination.

Candidates with backgrounds in small molecule crystallography or image processing of electron micrographs will also be considered. Please forward résumé and names of three references.

Contact: Professor Carolyn Cohen, Rosenstiel Basic Medical Sciences Research Center, Brandeis University, 415 South Street, Waltham, MA 02254.

An equal opportunity/affirmative action employer. (NW176)A

MARIE CURIE MEMORIAL FOUNDATION RESEARCH INSTITUTE POST DOCTORAL RESEARCH POSITIONS

to study the role of the cellular p53 oncogene in multi-stage carcinogenesis.

1. The role of p53 in SV40 and Adenovirus transformation. Reagents available include p53 deletion mutants that bind SV40T or E1b55k but are defective for cellular immortalization, point mutants that fail to bind the viral oncogene products and p53 antisense retroviral vectors.
2. Investigation of p53 mutants that exhibit enhanced activity in cellular immortalization assays.

These three year positions are funded on the University Lecturer scale.

Applications, C.V. and the names of two referees to Dr. J. Jenkins, MCMF Research Institute, The Chart, Oxted, Surrey, GU8 3PP (0883 333333) (7445)A

Cell Physiologist (PhD)

elf ^{bio}
recherches

Elf Bio Recherches, a subsidiary of Elf Aquitaine and Sanofi, specialises in biotechnology. It is looking for a Cell Physiologist for its laboratory of animal cell physiology and fermentation. This laboratory (2 scientists and 3 technicians) forms part of the recombinant animal cell technology unit. The research activities of this group include the investigation of the role of physiological factors involved in the expression of genes cloned into animal cells. Candidates should have a profound knowledge of animal cell physiology. Experience in medium or large-scale tissue culture will be an advantage. Knowledge of French would be appreciated. Elf Bio Recherches R & D facilities are located in the Toulouse area, in Southern France. Curriculum vitae and list of publications should be sent to Mr Fabre quoting Reference B/T 2018N. (W2149)A

PA

71 bis, allées Jean-Jaurès, 31000 Toulouse, France.
Tel: Toulouse 63.70.63.

MANAGING DIRECTOR

Boyce Thompson Institute at Cornell University

Applications and nominations are invited for the position of Managing Director of Boyce Thompson Institute for Plant Research at Cornell University. Boyce Thompson Institute (BTI) is a non-profit, privately endowed organization conducting research on plants and plant pests. The Institute is located in a facility completed in 1978 on the campus of Cornell University and is affiliated with the College of Agriculture and Life Sciences. BTI has an annual budget of \$7-8 million and employs approximately 125 scientists and support staff, 60 at the Ph.D. level.

The Managing Director serves as chief executive officer and is responsible for formulation of Institute policy, evaluation of productivity of research programs, selection of scientific personnel, recruitment of research support and overall operation of the Institute and interaction with Cornell University administration.

Selection will be based upon experience consistent with the goals of the Institute, which include basic and applied research in the plant sciences relevant to national and world agriculture. Previous scholarly endeavor, organizational ability and success in recruiting research support will be considered.

Applicants should send curriculum vitae, bibliography and names of five professional people acquainted with the applicant's background to Dr. Leonard H. Weinstein, Chairman of the Screening Committee, Boyce Thompson Institute at Cornell University, Ithaca, NY 14853. Nominations should also be sent to Dr. Weinstein. All applications and nominations should be submitted as soon as possible but not later than October 15, 1985.

An Affirmative Action/Equal Opportunity Employer. (NW179)A

DIRECTOR (male or female)

vacancy number 5-2221/2407

The Royal Dutch Academy of Letters, Arts and Sciences for the "Centraalbureau voor Schimmelcultures" at Baarn, The Netherlands.

The "Centraalbureau voor Schimmelcultures" (CBS - Central Institute for Fungal Cultures), with its main Laboratory in Baarn and its smaller yeast department in Delft, is an institute for research into the taxonomy of fungi (including yeasts) and actinomycetes. The CBS also houses, and is responsible for the management of, an extensive collection of fungi, yeasts and actinomycetes. The institute employs 15 scientists and 26 other staff members.

First choice will be given to a taxonomic mycologist but microbiologists with relevant experience or interests will also be considered. The candidate will be expected to hold a doctorate. In addition to being an efficient manager the director should have outstanding scientific qualities. He/she coordinates the entire research programme of the Institute in addition to pursuing his/her own research. He/she also has final responsibility for financial and technical supervision. The position is located in Baarn.

Salary: depending on age and experience, max. Dfl 9495,- per month. Further details can be obtained from the secretary of the selection committee, Professor K. Verhoeff, Willie Commelin Scholten Phytopathological Laboratory, 20 Javalaan, Baarn, The Netherlands (tel. 02154-15654).

Please send your application for 13th September 1985 to the Rijks Psychologische Dienst, Postbus 20013, 2500 EA The Hague, Holland.

(W2162)A

SENSORY NEUROBIOLOGIST

The Department of Neurobiology and Physiology at Northwestern University is seeking applications for a faculty position, at the level of Professor or Associate Professor in the general area of Sensory Neurobiology. The successful candidate will have a strong, well-established program of research, preferably in developmental or cellular/molecular neurobiology dealing with one of the sensory systems.

The Department of Neurobiology and Physiology has strong, well-funded groups in Sensory Neurobiology and in Neuroendocrinology, both representing multidisciplinary approaches to these areas of Neuroscience. The Department currently administers a PhD program; two NIH training programs are centred in the department. The Department also has an undergraduate major leading to a BA, and a BA/MS honours program for exceptional undergraduates.

Interested persons should submit a curriculum vitae and the names of three persons who can provide references to:

Dr. Albert I. Farbman,
Department of Neurobiology and Physiology,
Northwestern University,
Hogan Hall, Evanston, IL 60201.

Northwestern University is an Equal Opportunity/Affirmative Action Employer. (NW167)A

** SENIOR SCIENTIST **

The W. Alton Jones Cell Science Center, Inc., Lake Placid, New York has an immediate opportunity for an innovative and experienced molecular biologist to direct independent research in the field of molecular and cellular biology.

We are seeking a dedicated and talented scientific professional with interest in cell biology and growth factors. The successful candidate will have a doctorate in molecular and cellular biology with at least 3 years postdoctoral experience. Candidates must have the ability to supervise others. Liberal benefits. Salary will commensurate with experience.

Applicants are requested to submit complete curriculum vitae and to have three letters of academic references forwarded by October 1, 1985 to:

Personnel Manager
W. ALTON JONES CELL SCIENCE CENTER,
10 Old Barn Road
Lake Placid, New York 12946

AN AFFIRMATIVE ACTION/EQUAL OPPORTUNITY EMPLOYER

M.R.C. CLINICAL RESEARCH CENTRE
(NORTHWICK PARK HOSPITAL)
WATFORD ROAD, HARROW
MIDDLESEX HA1 3UJ

NON-CLINICAL SCIENTIST

Applications are invited from Electron Microscopists for this 3 year appointment in the Division of Clinical Cell Biology to investigate the uptake and intracellular processing of various ligands by hepatocytes with special reference to the involvement of lysosomes and related organelles. There will be collaboration with other scientific staff of the Division and the section of Histopathology in the use of EM facilities.

Salary will be within the range £10153-£16158 (inclusive of London weighting) depending on qualifications and experience.

For an opportunity to visit the Division contact Dr. T.J. Peters on 01-864 5311 Extn. 2139.

Application forms available from Betty Shaw, Personnel section quoting reference 104/1/3963. Closing date for completed application forms, 19th September, 1985. (7507)A

SENIOR RESPIRATORY PHARMACOLOGIST AT SEARLE

G.D. Searle is a major international Pharmaceutical Company whose Research & Development Division at High Wycombe has several exciting programmes in the field of chemically and biologically derived products.

We are seeking an experienced postdoctoral pharmacologist to lead a new team investigating the pathological mechanisms of human respiratory disease. An all round understanding of respiratory pharmacology is essential and he or she will be expected to contribute expert theoretical and practical knowledge to the project. Frequent interaction with other departments and external academic centres will be necessary. Relevant experience within an

industrial environment would be an advantage, but is not essential.

The Company offers competitive salaries, 23 days holiday, contributory pension fund, health insurance scheme, subsidised cafeteria, recreation club and modern offices in a very pleasant location. Generous relocation assistance will be available in appropriate cases.

Please apply to the Personnel Manager, Searle Research & Development, Lane End Road, Sands, High Wycombe, Bucks. (Tel. High Wycombe 21124 Ext. 3372). Please quote reference B1362.

(7522)A

SEARLE

UNIVERSITY OF ULM

DEPARTMENT OF CLINICAL PHYSIOLOGY AND OCCUPATIONAL MEDICINE

(Director: Prof. Dr. med. T.M. Fiedner)

There is a vacancy to be filled as soon as possible (of 4 to 5 years duration) in the Euratom-Project of radiation-hematology as a scientist (BAT II/b). Final signature of the contract is reserved. Candidates should have a Ph.D. or equivalent with a dissertation in a biomedical field as well as having experience with cell cultures, cell separation methods and/or analysis of regulating factors.

Please send your application along with a list of your publications, certificates, reference letters and curriculum vitae to — Prof. Dr. rer. nat. W. Nothdurft, Abteilung für Klinische Physiologie und Arbeitsmedizin der Universität Ulm, Oberer Eselsberg M 24, 309 D-7900 Ulm/Donau.

(W2164)A

LIVERPOOL SCHOOL OF TROPICAL MEDICINE

Wolfson Molecular Genetics Unit/ Venom Research Unit

RESEARCH ASSISTANT

to join a project, funded by the MRC, investigating the molecular biology of snake venom antigen genes. Applicants should have a good honours degree in a relevant subject; some experience of molecular biology would be an advantage.

The post will be for a period of 3 years with a starting salary of £6,600. The successful applicant would be encouraged to register for a Ph.D.

Applications, including full c.v. and the names of two referees, should be sent by 14 September to Dr J. M. Crampton, Wolfson Molecular Genetics Unit, Liverpool School of Tropical Medicine, Pembroke Place, Liverpool L3 5QA.

(7512)A

SENIOR RESEARCH ASSOCIATE/ POST DOCTORAL ASSOCIATE

Applications are invited from interested persons for the positions of Senior Research Associate/Post Doctoral Associate in the Wits-CSIR Schonland Research Centre for Nuclear Science for initial appointments of 3 years.

The spectrum of research at the Centre is wide and embraces fundamental nuclear and atomic physics as well as the application of nuclear techniques in metallurgy, geology, mineralogy, hydrology and biology.

Further information can be obtained from Mr. Geoff Henning, South African Universities Office, Chichester House, 278 High Holborn, London WC1V 7HE. Interested parties should submit a detailed curriculum vitae, with names and addresses of 3 referees by 30th September 1985.

It is the policy of the University not to discriminate on the grounds of sex, race, colour or national origin.

(W2159)A

UNIVERSITY OF
WITWATERSRAND

MEDICAL RESEARCH COUNCIL

The MRC Tuberculosis and Related Infections Unit at the Hammersmith Hospital, London W12 0HS requires postdoctoral scientists for the following positions:

POSITION "A": A biochemist/molecular biologist interested in the structural analysis of antigenic determinants of mycobacterial proteins recognised by cloned T-cell subsets. Background experience in peptide and/or recombinant DNA technologies would be desirable.

POSITION "B": An immunologist interested in the immunomodulatory function of molecules isolated from mycobacteria cell walls. Background experience in immunobiology and immunogenetics in murine models would be desirable.

POSITION "C": An immunologist interested in genetic (HLA-D) requirements of cellular interactions in the human immune response to mycobacterial antigens. Background experience in lymphocyte tissue culture and/or HLA studies would be beneficial.

All three appointments are for a period of 3 years with a possibility of extension up to 5 years. Remuneration will be based on the University non-clinical academic staff scales. Applications should be submitted to the Director of the Unit, Dr. J. Ivanyi (address above, phone 01-743-4594, Ext. 67). (7493)A

MRC
Medical Research Council

Faculty Position available, tenure-track, in molecular genetics, with a special interest in membranes. Applicants should have research background in recombinant DNA technology (preferably also in somatic cell genetics) and working knowledge of membrane proteins. M.D. and/or Ph.D. in appropriate field required. Successful candidate will hold tenure-track appointment (Assistant or Associate Professor, depending upon qualifications) in Department of Physiology and Molecular Biophysics at Baylor College of Medicine. Joint appointments in relevant academic departments also possible. Laboratory space and basic equipment provided and initial laboratory support available. Successful candidate will devote majority of his/her effort to establishing and maintaining an independent research program related to the main interests of the Department. The Department is building a strong program in membrane biophysics with expertise in electrophysiology, membrane biochemistry, reconstitution, and modelling. **Send vita, a brief description of past and present research experience, and names of three or more references to**

**Dr. A. M. Brown, Incoming Chairman,
Physiology and Molecular Biophysics Department**

**Baylor College of Medicine,
One Baylor Plaza,
Houston, Texas 77030.**

An Equal Opportunity A/A Employer

(NW58)A

BIOCHEMIST

to study long-term biochemical regulation of membrane channels within an established multidisciplinary program investigating molecular substrates of learning and memory. High resolution, two-dimensional gel electrophoresis; HPLC, auto-radiography; enzymatic assays (eg. kinases, adenylate cyclase, phosphatase, etc); protein synthesis, recombinant DNA techniques; and artificial membranes are examples of desirable areas of expertise.

Candidates with a PhD and/or MD and at least two years post-doctoral experience preferred. Salary range \$25,000-\$35,000 with excellent benefits.

Submit resume to Personnel Office, Marine Biological Laboratory, Woods Hole, MA 02543 by September 20, 1985

The MBL is an Affirmative Action/Equal Opportunity Employer.

(NW181)A

CLINICAL SCIENTIST

Astra is an international pharmaceutical company with a strong commitment to research. The Astra Clinical Research Unit in Edinburgh has an opportunity for an experienced clinical scientist to participate in our expanding programme of clinical trials in the field of gastroenterology.

The successful candidate should be able to communicate effectively and possess a post-graduate qualification in a life science discipline, with ideally 2 or 3 years relevant experience in the pharmaceutical industry.

A competitive salary and benefits package will be offered.

Applications enclosing a detailed C.V. should be marked Confidential and addressed to:

**THE DIRECTOR OF CLINICAL RESEARCH

10 York Place
Edinburgh, EH1 3EP
SCOTLAND**

(7524)A

UNIVERSITY OF NOTTINGHAM

DEPARTMENT OF APPLIED
BIOCHEMISTRY AND
FOOD SCIENCE

Applications are invited for a
RESEARCH ASSISTANT

to work on neutral protease activity in muscle of farm species. The proposed starting date is November 1st 1985. The project is in association with a large international company and it is hoped to publish the results in the scientific literature. The project is planned to last three years and will be supervised by Dr R G Bardsley and Professor P J Buttery. Suitable applicants will have a thorough training in biochemistry or a related subject. Knowledge of protein separation techniques would be an advantage. Preference will be given to applicants with previous postgraduate experience. A desire to relate their studies to problems of agricultural importance would be a great advantage.

The Department has well equipped laboratories for biochemical studies with farm animals and it is situated on the Sutton Bonington Campus of the University, some 6 miles north of Loughborough.

Salary will be on the research and analogous staff scales with a starting salary up to £8,920 (under review) with USS benefits.

Applications giving the names of two academic referees and including a curriculum vitae should be addressed to the Secretary, University of Nottingham School of Agriculture, Sutton Bonington, Nr Loughborough, Leics, LE12 5RD to arrive as soon as possible. (7500)A

THE INSTITUTE OF CANCER RESEARCH, AND THE ROYAL MARSDEN HOSPITAL

CLINICAL RESEARCH
ASSISTANT/DATA
COLLECTOR

Applications are invited for the above post in the Section of Radiotherapy, Sutton, Surrey. The holder of the post will be particularly involved with handling clinical data pertaining to patients with malignant lymphoma, entering such data on to a computer terminal and working closely with clinicians and statisticians in the analysis of treatment results. The post would be suitable for a non-clinical science graduate.

Salary in the range of £5738 - £8096 p.a. + £648 p.a. Outer LWA depending on qualifications and experience.

Applicants are advised that in the majority of The Institute's premises, smoking is prohibited.

Applications in duplicate with the names and addresses of two referees should be sent to the Personnel Officer, The Institute of Cancer Research, 17A Onslow Gardens, London, SW7 3AL, quoting refer-

THE NATURE CONSERVANCY COUNCIL

Specialist in Scientific
Data-Handling

**HIGHER SCIENTIFIC
OFFICER/SENIOR
SCIENTIFIC OFFICER**

Applications are invited for the above permanent post within the Chief Scientist Directorate based at the Council's Great Britain House, Peterborough. The holder will be responsible for maintaining and developing computer systems for the general support of scientific staff and in the development of the computerisation of NCC's licensing records, as well as other duties.

Qualifications. Candidates should have a degree in an appropriate subject and at least 2-4 years post graduate experience. Essential expertise will include a sound knowledge of data management for scientific purposes and of scientific data analysis. Preference will be given to candidates with experience of managing biological information and analysis.

Salary, depending on qualifications and experience.

HSO £7,785 rising to £10,541

SSO £9,772 rising to £12,653.

For an application form and further details of the post please contact, Miss B A Meredith, Person I, Nature Conservancy Council, Northminster House, Peterborough PE1 1UA, to whom completed forms should be returned by September 1985.

The Nature Conservancy Council is an equal opportunity employer. (7504)A

CHARING CROSS MEDICAL RESEARCH CENTRE

IMMUNOLOGY UNIT
RESEARCH ASSISTANT

Applications are invited from workers with wide experience in biochemistry, immunochemistry and cellular immunology (in vitro and vivo assays) for a position as research assistant to work with Dr M Feldmann on a project to analyse mechanisms of HLA Class II antigen regulation in disease. Preference will be given to candidates with an interest in immune regulation and capable of independent research.

Appointment will be for 1 year first instance, with starting salary the appropriate point of Research 1A scale, depending on age, qualifications and experience.

Applications (with curriculum vitae, and name of two referees) should be sent to:

The Administrator, Charing Cross Medical Research Centre, Lurg Avenue, Hammersmith, London W6 8LW

Applications should arrive by.

THE AUSTRALIAN NATIONAL UNIVERSITY

Research School of
Earth Sciences

POSTDOCTORAL FELLOW/ RESEARCH FELLOW/ SENIOR RESEARCH FELLOW IN GEOPHYSICAL FLUID DYNAMICS

Applications are invited from suitably qualified men and women for appointment as Postdoctoral Fellow Grade 1, Research Fellow or Senior Research Fellow in Geophysical Fluid Dynamics in the Research School of Earth Sciences. Double-diffusive convection is a central theme of the research of the Geophysical Fluid Dynamics Group headed by Professor J S Turner. Candidates are sought with interests in one or both of the following fields: (a) Laboratory studies of fluid dynamical processes in the interior of the earth including layered magnetic intrusions, variable viscosity in magma mixing, the withdrawal of fluid from magma chambers, diapir motion and large-scale convection in the mantle; (b) Laboratory and theoretical studies of mixing in the ocean. Applications from candidates with backgrounds in petrology or tectonophysics who are interested in quantitative modelling of problems in category (a) would be particularly welcome.

Closing date: 27 September 1985.
Ref: ES 11/7/1.

Conditions of appointment: Salary will be in accordance with qualifications and experience within the range: Postdoctoral Fellow Grade 1 \$A22,614-\$25,905 pa; Research Fellow \$A26,236-\$34,467 pa; Senior Research Fellow \$A36,649-\$43,715 pa; current exchange rate: £A1 = UK51p.

Appointment will be: Senior Research Fellow/Research Fellow normally up to three years with the possibility of extension to maximum of five years; Postdoctoral Fellow normally two years, with the possibility of extension to maximum of three years.

Grants are provided towards travel and removal, though special conditions may apply to persons appointed to externally funded positions. Assistance towards housing is given to an appointee from outside Canberra. Eligible appointees will be required to join the Superannuation Scheme for Australian Universities. Maternity leave is available. The University reserves the right not to make an appointment or to make an appointment by invitation at any time.

Applications should be submitted to the Acting Registrar, Australian National University, GPO Box 4, Canberra, ACT2601, Australia. Applicants should quote the reference No. when submitting applications and when requesting further particulars which are also available from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

The University is an equal opportunity employer.

CAREER OPPORTUNITY ONCOGENE SCIENCE, INC.

Is seeking to expand its staff at Long Island, NY research facilities for programs in

**Oncogene and growth factor research
in order to develop products for early
detection -- monitoring -- treatment
of human cancer.**

— Position Available —

DIRECTOR OF DIAGNOSTIC R&D PROGRAMS

Responsibilities include management of basic research and product development programs for human cancer diagnostics including strategic R&D planning and coordination of contract research with corporate sponsors. Successful candidate will have Ph.D. with experience in management of research and development programs in industrial setting particularly in the area of immunodiagnostics; knowledge of oncogene/growth factor research would be an asset.

Send resume to Scientific Director, Oncogene Science Inc.,
222 Station Plaza North, Suite 330, Mineola, NY 11501.

**Competitive salary. Liberal benefits.
Equity participation.**

(NW189)A

Equal Opportunity Employer

UNIVERSITY OF CAMBRIDGE

Post-graduate/post-doctoral

RESEARCH ASSISTANT NEUROENDOCRINOLOGIST

To join multi-disciplinary neuroendocrine research group in MRC supported project to investigate the neural basis of photorefractoriness in seasonal breeding. Background in endocrinology/neuroscience preferable.

Post available autumn 1985 for three years. 1A salary scale.

Applications and further details: Mrs J Penton, Dept of Anatomy, University of Cambridge, Downing Site, Camb CB2 3DY. Please arrange for 2 referee's reports to

RADIOCHEMIST

engaged in various research and development activities in the field of radiochemistry leading to commercial applications in medicine and industry. Review existing production processes, assess and solve problems associated with specifications, quality cost and safety. BA in Chemistry, 3-4 yrs. exp. \$673.75 pr. wk., job sit/interview Burbank.

Send this ad and your resume to:

Job # NOF 5147,
P.O. Box 9560,
Sacramento,
Calif. 95823-0560,
not later than Sept 15 1985.

(NW195)

FACULTY POSITION MOLECULAR BIOLOGIST

Tenure track opening for a molecular biologist at the Assistant or Associate Professor level in the Department of Chemistry and Biochemistry at Texas Tech University for the Fall semester of 1986. Experience with recombinant DNA techniques and/or related molecular biological methods required. Prior to October 16, 1985, applicants should forward a resume and description of proposed research and arrange to have three letters of recommendation sent to: Professor Pill-Soon Song, Department of Chemistry and Biochemistry, Texas Tech University, Lubbock, Texas 79409. Texas Tech University is an EO/AA employer. (NW174)A

TWO RESEARCH POSITIONS IN THE NEUROSCIENCES:

Molecular Neurobiologist/Molecular Geneticist

Applications are invited for molecular neurobiologists and/or molecular geneticists, by the Mental Health Research Institute of The University of Michigan. The Institute's scientists have research interests in a variety of areas including membrane phospholipids, PET scanning, neuropeptides, molecular biology, phosphoproteins, biological psychiatry, and neuroendocrinology.

Level of appointment and salary will be commensurate with experience and qualifications. Applicants should have a Ph.D. and/or M.D., at least two years post-doctoral research training, and a strong commitment to a research career in the neurosciences.

Successful applicants will devote the majority of their time to the establishment of original, independent, research programs within the Institute. It is also expected that the applicant will hold a joint appointment in an appropriate academic department of the University. Access to graduate students and post-doctoral fellows is via relevant departments and interdepartmental degree programs. An interdisciplinary training program provides stipends for M.D. and Ph.D. research fellows. Investigators' salaries are supported by the Institute.

The deadline is December 15, 1985. Applications should be accompanied by a curriculum vitae, a statement of research interests, selected papers, and the names of three references to **Stanley Watson, Ph.D., M.D., Associate Director, Mental Health Research Institute, 205 Washtenaw Pl., The University of Michigan, Ann Arbor, MI 48109**.

(NW190)A

The University of Michigan

An equal opportunity/affirmative action employer

UNIVERSITY OF BRISTOL

DEPARTMENT OF ZOOLOGY

Postdoctoral position in

MOLECULAR NEUROBIOLOGY

Applications are invited from scientists holding a PhD in Biochemistry, Molecular Genetics, or a related field, with experience in DNA manipulation and hybridisation techniques, and a record of research in any aspect of the control of transcription in eukaryotic cells.

The project, which is funded by the Wellcome Trust, aims to investigate the control of expression regulatory peptides implicated in cellular differentiation and synapse formation in mammalian neurones.

Laboratory facilities will be provided in the newly-established Molecular Genetics Unit at Bristol.

An appointment will be made at the University Academic Staff Range 1A at a starting salary of £7,520 — £9,390 per annum.

Initial enquiries may be made to Dr. L. W. Haynes, Department of Zoology, The University of Bristol, Woodlands Rd, Bristol BS8 1U (0272 24161 ext 57) to whom applications, accompanied by cv and three names of three referees should be addressed before 4 October.

(7518)A

The University of Alberta

Department of Microbiology Edmonton, Canada

The Department of Microbiology, University of Alberta, invites applications for an independent research position from qualified individuals with demonstrated research and teaching abilities in molecular virology, or in the use of biochemical approaches to basic and applied problems in microbiology. Candidates should have a recent Ph.D. and relevant post-doctoral experience.

The position is a 5 year term appointment at the Assistant Professor level (approximate salary \$30,000), and will be contingent upon a successful application for a competitive award from an external agency. Duties include development of an independent research programme, graduate student supervision and some appropriate classroom teaching.

The Department of Microbiology has 10 permanent staff members with research interests which include basic and applied aspects of microbiology, virology, cell biology and immunology. Active collaborative interests are also maintained with the faculties of Medicine, Dentistry, Engineering, Agriculture/Forestry, etc. The department offers undergraduate, M.Sc. and Ph.D. programmes.

The university has an enrolment of 28,000 full-time students and is located in Edmonton, a city of 700,000, which is the provincial capital of Alberta.

Applications, containing a curriculum vitae, names and addresses of 3 referees, and a concise but specific description of research interests and proposed work should be sent to:

**Chairman, Selection Committee, Department of Microbiology
The University of Alberta, EDMONTON, Alberta, Canada T6G 2E9**

The University of Alberta is an equal opportunity employer, but in accordance with Canadian immigration requirements, priority will be given to Canadian citizens and permanent residents of Canada.

(NW185)A

This advertisement appeared in the 1 August 1985 issue
with an incorrect salary.

NORDITA COPENHAGEN

ASSISTANT PROFESSOR IN THEORETICAL CONDENSED MATTER PHYSICS AND RELATED SUBJECTS

NORDITA, the Nordic theoretical physics institute, located at the Niels Bohr Institute of Copenhagen University has an opening starting in January 1986, or later if that is more convenient, for an assistant professor in theoretical condensed matter physics, or chaos, or in the physics or biomolecules.

The successful applicant is expected to guide fellows at roughly the postdoctoral level and to interact with colleagues at NORDITA and elsewhere in the Nordic countries. The position provides excellent opportunities to pursue original research and to have contact with a wide range of developments in theoretical physics. There are good facilities for travelling to other institutes and to meetings outside the Nordic countries; and the assistant professor will be encouraged to invite guest scientists to NORDITA. The initial appointment will be for three years, with the possibility of renewal up to a total of six years. The annual salary will be in the range of 190,000-270,000 Danish Kroner depending on experience.

Those interested in the appointment should send curriculum vitae, a list of publications and the names of three referees before 1 November 1985 to the Director, Nordita, Blegdamsvej 17, DK-2100 Copenhagen Ø, Denmark. There is no restriction on the nationality of the applicant. Those wishing to recommend suitable candidates are urged to contact the Director.

(W2152)A

**THE UNIVERSITY OF
PAPUA NEW GUINEA**
Port Moresby

Applications are invited from suitably qualified and experienced persons for the following position

**LECTURER/SENIOR
LECTURER IN BIOLOGY
DEPARTMENT—
W021006/85**

Applications are invited from qualified biologist with teaching and research experience in invertebrate biology. The successful applicant will be required to co-ordinate team taught courses in invertebrate biology and crop protection/industrial biology as well as participate in introductory courses. A research interest in terrestrial invertebrate biology, especially applied entomology, is desirable. The University maintains a large invertebrate teaching/ reference collection and hence an interest in animal curation would be an advantage. Experience in a tropical developing country would also be desirable.

Salaries: Senior Lecturer K21255, Lecturer Grade 2 K19405, Lecturer Grade 1 K17555, per annum, plus gratuity

Other conditions: The successful applicant will be normally offered a contract for a three year period ending at the end of a semester. The gratuity entitlement is based on 24% of salary earned and is payable in instalments or lump sum and is taxed at a flat rate of 2%. In addition to the salaries quoted above, the main benefits include support for approved research; rent-free accommodation, financial assistance towards the cost of transporting personal effects to and from PNG; 6 weeks annual recreation leave with some airfares available after each 18 months of continuous service; generous education subsidies for children attending schools in PNG and overseas, a salary continuation scheme to cover extended illness or disability. Applicants wishing to arrange secondment from their home institutions will be welcomed. The terms and conditions are under review.

Applications, will be treated as strictly confidential and should include a full curriculum vitae, a recent small photograph and the names and addresses of three referees. In order to expedite the appointment procedure, applicants are advised to ask their referees to send confidential reports directly to the University without waiting to be contacted. Applications should be forwarded to the Deputy Registrar (Staffing), University of Papua New Guinea, PO Box 320, University Post Office, Papua New Guinea, by 20 September 1985. Candidates in UK should so send a copy of their application to the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. (W2167)A

when replying to
these advertisements.

THE AUSTRALIAN NATIONAL UNIVERSITY

Applications are invited from suitably qualified women and men for appointment to the following positions

JOHN CURTIN SCHOOL OF MEDICAL RESEARCH

Department of Experimental Pathology

FELLOW/SENIOR FELLOW IN CANCER BIOLOGY

Cancer Research was initiated in the Department of Experimental Pathology in 1982 with research activity concerned with analysing the biological basis of tumour metastasis and malignancy. The Department plans to commit a substantial proportion of its resources to this area and seeks to appoint a Fellow or Senior Fellow to lead this research activity. Preference will be given to applicants with strengths in aspects of cancer cell biology relevant to malignancy and pathogenesis.

The current research effort is well developed in the areas of cell biology, somatic cell genetics and protein chemistry and is expected to incorporate an increasing component of molecular biology. The tumour metastasis and malignancy program will thus provide a focus for the further dissemination of molecular biology techniques into other activities within the Department.

Further particulars are available on request; enquiries to the Head of Department, Professor P C Doherty, FAA, (062) 492524.

Closing date: **27 September 1985** Ref: JC 8.8.1

Department of Pharmacology

FELLOW/SENIOR FELLOW IN NEUROPHARMACOLOGY

Applications are invited from neuropharmacologists/neurophysiologists experienced in investigating transmitter actions at a cellular level in the mammalian central nervous system using microelectrophoretic and intra/extracellular recording techniques, for appointment as Fellow or Senior Fellow, to undertake independent research in the area of neurotransmission and to interact with other researchers with interests in identification of transmitters and the study of transmitter and drug action at central synapses. Preference will be given to applicants whose interests lie predominantly in the area of excitatory amino acid neurotransmission, studies under in vivo conditions.

Further particulars are available on request; enquiries to the Head of Department, Professor D R Curtis, FAA, FRS, (062) 492037

Closing date: **27 September 1985**. Ref: JC.8.8.2.

RESEARCH SCHOOL OF EARTH SCIENCES

**POSTDOCTORAL FELLOW/RESEARCH FELLOW IN
EXPERIMENTAL PETROLOGY**

The appointee will work in the Petrochemistry Group with Professor A E. Ringwood and Dr T. Irifune in the field of experimental petrology, and will also have adequate opportunity to pursue independent experimental research in fields of interest to the Petrochemistry Group.

Candidates are sought who are particularly interested in applying the methods of experimental petrology to geochemical, petrological and geophysical processes occurring in subduction zones and in the subcontinental lithosphere. Topics of interest to the group include high pressure phase transformations and mantle petrology in subduction zones including their bearing on geodynamical processes, the petrogenesis of subduction-related magmas and the geochemical evolution of the mantle. The group is also interested in the petrology and geochemistry of the subcontinental lithosphere, including problems relating to the origin of diamonds and kimberlites. Alternatively, applications from candidates who wish to apply the techniques of experimental petrology to broader aspects of planetology, including the internal constitution and origin of the moon, would also be welcomed.

Laboratory facilities available to the Petrochemistry Group include a wide range of solid pressure media, high P-T apparatus (to 180 kb, 3000deg C) together with diamond anvil systems equipped with laser heating. High temperature furnaces equipped for experimentation under controlled oxygen fugacities are also available. Extensive facilities for chemical microanalyses, X-ray and other studies of high pressure samples and phases also exist within the school. They include two electronprobe microanalyzers, X-ray diffraction apparatus, 300 KV transmission electron microscope and ultrasonic equipment for measurements of elastic properties of minerals.

Enquiries to Mr D. Glenn (062) 49-2865

Closing date: **18 October 1985**. Ref: ES.1 8.1

FACULTY OF SCIENCE

Department of Forestry

**LECTURERS IN SOIL SCIENCE/WOOD SCIENCE/FIRE SCIENCE AND
MANAGEMENT (THREE POSITIONS)**

Soil Science: The appointee will be responsible for teaching a second-year undergraduate course in forest soils and will contribute to some later year courses. Qualifications: A PhD in soil science and a proven potential for research. Experience and expertise in forest soils would be an advantage but in the absence of such experience the appointee must be willing to develop an interest and expertise in forest soil science.

Wood Science: The appointee will be responsible for teaching a second year undergraduate course in wood science with an emphasis on anatomy in relation to wood properties and will also participate in teaching a later course dealing with chemical and physical properties of wood in relation to wood utilisation. Qualifications: A PhD in wood science or related discipline and a proven potential for research.

Fire Science and Management: The appointee will be responsible for the teaching of fire science (flammability of fuels, fire behaviour, fire weather) and the practical application of fire management in forested lands and also will be expected to liaise with CSIRO forest fire researchers, with State forest services and with other organisations responsible for rural fire management. Qualifications: A PhD in forest fire science or in an appropriate related discipline (e.g. physics, micrometeorology) with a willingness to apply this expertise to forest fire science and management. Applicants without such qualification but with considerable experience in Forest fire science and management are also encouraged to apply. A proven potential for independent research is essential.

The successful applicant in each position will be required to carry out independent research and supervise postgraduate students in the specified field.

Closing date: **27 September 1985**. Ref: FS8.8.1.

CONDITIONS OF APPOINTMENT: Salary will be in accordance with qualifications and experience within the range: Postdoctoral Fellow Grade 1 \$A22,614 — \$25,905 p.a.; Research Fellow \$A26,236 — \$34,467 p.a.; Fellow \$A30,585 — \$40,975 p.a.; Senior Fellow \$A41,029 — \$47,823 p.a.; Lecturer \$A26,236 — \$A34,467 p.a.; current exchange rate: \$A1 = UK50p.

Appointment will be Research Fellow normally up to three years with the possibility of extension to maximum of five years; Postdoctoral Fellow normally two years, with the possibility of extension to maximum of three years. Appointment as Fellow or Senior Fellow is for an initial period of five years with the possibility, following review, of reappointment to retiring age 65. Appointment as Lecturer will be for four years in the first instance with the possibility, after review, of appointment to retiring age.

Grants are provided towards travel and removal. Assistance towards housing is given to an appointee from outside Canberra. Eligible appointees will be required to join the Superannuation Scheme for Australian Universities. Maternity leave is available. The University reserves the right not to make an appointment or to make an appointment by invitation at any time. Applicants should quote the advertisement reference when submitting applications, and when requesting further particulars, which are also available from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Applications should be submitted to the Acting Registrar of the University, GPO Box 4, Canberra, ACT 2601, Australia.

THE UNIVERSITY IS AN EQUAL OPPORTUNITY EMPLOYER

(W2165)A

FACULTY POSITION IN ASTRONOMY THE PENNSYLVANIA STATE UNIVERSITY The Department of Astronomy

invites applications for a tenure track faculty appointment. This is a position recently added to the existing staff of nine regular faculty members and seven postdoctoral research associates in the Department. While our primary goal is to find an outstanding young astronomer appropriate for appointment at the assistant professor level, an appointment at a higher rank is also possible for an exceptionally qualified candidate. A few years postdoctoral experience is desired. Any area of theoretical or observational astronomy and astrophysics will be considered. Teaching experience is important, but outstanding research ability is the most essential qualification, as the appointee is expected to carry out a vigorous research program.

Department facilities include the Black Moshannon Observatory 1.6m telescope (equipped with high and low resolution fiber-coupled CCD spectrographs); a supermicro image processing computer (for VLA and CCD data reduction); access to a Cyber 205 supercomputer; and laboratories for the development of X-ray reflecting mirrors, detectors, and shuttle experiments.

The position can be filled as soon as a qualified candidate is found. Applications received by November 1 will receive first round consideration. Interested applicants are requested to send to the undersigned a curriculum vitae, a summary of proposed research activity, teaching experience, and the names of at least three referees.

Dr. Satoshi Matsushima, Head, Department of Astronomy, 525 Davey Laboratory, University Park, PA 16802, Tel: 814-865-0410.

The Pennsylvania State University is an Equal Opportunity/Affirmative Action Employer.

(NW180)A

UNIVERSITY OF LONDON Royal Holloway and Bedford New College POSTDOCTORAL RESEARCH FELLOW AND RESEARCH TECHNICIAN (Grade 5)

to work with Dr R A Dixon, Department of Biochemistry, on the structure and expression of plant genes involved in resistance to fungal pathogens. Both positions are for 3 years, and will be funded by the Agricultural and Food Research Council. Experience in recombinant DNA techniques is essential, the technical post will largely involve DNA sequencing.

Starting salaries will be £7,101 (technician), and up to £10,153 (postdoctoral fellow), both inclusive of London Allowance.

Applications, including a curriculum vitae and the names and addresses of two referees, should be sent to the Personnel Officer, Royal Holloway and Bedford New College, Egham Hill, Egham, Surrey, TW20 0EX (7502)A

UNIVERSITY OF NOTTINGHAM DEPARTMENT OF AGRICULTURE AND HORTICULTURE Vacancies are available from 1st October 1985 for:—

(I) POST DOCTORAL RESEARCH FELLOW (II) GRADUATE RESEARCH ASSISTANT

Salaries in the range of £7,520 — £8,920 and £6,600 — £7,520 respectively. These posts are funded by grants from MAFF and the EEC Commission to carry out work in co-operation with the Plant Breeding Institute, Cambridge on agronomic and physiological studies in novel forms of winter and spring beans in relation to breeding objectives. Both posts are for a period of 2 years in the first instance.

Applicants should send a full Curriculum vitae and the names of two referees to Dr P D Hebblethwaite, School of Agriculture, University of Nottingham, Sutton Bonington, Loughborough, Leics. LE12 5RD by 18th September 1985 (7501)A

UNIVERSITY OF UTAH

As part of a cooperative program with the Department of Biology, the Department of Chemistry is inviting applications for a tenure-track Assistant Professorship for individuals whose research interests are in the area of structure and function of biological macromolecules. The selected candidate is expected to demonstrate excellence and creativity in research and to play an active role in teaching. Preference will be given to individuals who apply modern chemical methods to the study of proteins or nucleic acids in areas which complement existing programs.

Send résumé including a description of research plans and three letters of reference by 10/1/85 to Professor C.D. Poulter, Department of Chemistry, University of Utah, Salt Lake City, Utah 84112. The University of Utah is an equal opportunity/affirmative action employer (NW1918)A

UNIVERSITY OF BIRMINGHAM Faculty of Medicine and Dentistry

DEPARTMENT OF PHYSIOLOGY RESEARCH FELLOW

Applications invited for a 2 year post doctoral appointment funded by the Medical Research Council to work on Synaptic physiology and pharmacology of sympathetic preganglionic neurones using an in vitro preparation. Experience with tissue slice preparations would be an advantage.

Salary in range £7,520 — £12,150 with superannuation maximum starting £8,920

Further details may be obtained from Professor J H Coote, Department of Physiology, The Medical School, University of Birmingham, B15 2TJ.

Applicants should send a cv including list of publications and names of 2 referees to the Assistant Registrar, Medical School, Birmingham B15 2TJ, by 21 September 1985. (7490)A

UNIVERSITY OF BIRMINGHAM DEPARTMENT OF SPACE RESEARCH POST-DOCTORAL RESEARCH FELLOW (REF E2)

Required, as a member of a team, to develop, test and integrate software for the mission operations and data processing associated with the wide field soft X-ray camera to be flown on Rontgensatellit in 1987, leading to a participation in the data analysis. Tenable for up to twenty seven months from 1/10/85 in the first instance and funded by the SERC on the Research Fellow 1A scale £7,520 — £12,150 plus superannuation.

For further particulars phone 021 472 1301 ext 2559, quoting reference E2.

No formal application form. Three copies of application including full curriculum vitae and naming three referees to Assistant Registrar (Science), PO Box 363, Birmingham B15 2TT, by 13 September 1985. (7523)A

MICROBIOLOGY POSTDOCTORAL POSITION

available January, 1985, to study membrane functions of H influenzae. Experiments involve manipulation of genes encoding outer membrane proteins and related functions. Support for up to three years.

Applicants should submit curriculum vitae and names of three referees to Dr Terrence Stull, Department of Microbiology, Medical College of Pennsylvania, 3300 Henry Avenue, Philadelphia, PA 19129. (NW1901)A

THE ROCKEFELLER UNIVERSITY POSTDOCTORAL POSITION

Available October 1985 investigate the effects of chromatin structure on DNA replication in cultured animal cells.

Send cv and names of three referees to: Box HOS W21 The Rockefeller University 1230 York Avenue, New York NY 10021. (NW178)A

POSTDOCTORAL POSITION

Immediately available at the University of California in San Diego. The position is for two years to work on the development of chimeric antibodies. Applicants should have some experience in molecular biology techniques.

Send curriculum vitae and references to: Dr. Roland Newman, University of California, San Diego Cancer Center, T-011, La Jolla, CA 92093.

(NW177)A

UNIVERSITY OF QUEENSLAND RESEARCH FELLOW — BIOCHEMISTRY

To join a group currently investigating gene expression in resistant susceptible cereals infected with rusts and powdery mildew fungi. Experience in recombinant DNA technology and DNA sequencing an advantage.

Salary per annum \$A26,236 \$A34,467. Please supply names of three referees. Closing date: 1 September, 1985. Ref: 33085

Application forms are available from the Secretary-General Association of Commonwealth Universities, 36 Gordon Square London WC1H 0PF.

The University of Queensland an Equal Opportunity Employer (W2157).

POSTDOCTORAL POSITION

available immediately to study zymology/regulation of processing of cytosolic protein precursor(s) of two chloroplast-localized glutamate dehydrogenase isoenzymes involved in NH_3 assimilation. Experience required in protein chemistry/enzymology, in vitro translation of poly(A)⁺ RNA, and Western blotting procedures. Salary \$18,000 per year. Dr. Robert Schmidt, Department of Microbiology and Cell Science, 10 McCarty Hall, University of Florida 32611. Affirmative Action/Equal Opportunity Employer. (NW197)A

NMR INSTRUMENTATION SPECIALIST

The Pennsylvania State University College of Medicine seeks candidates for the position of NMR INSTRUMENTATION SPECIALIST

Primary responsibilities include day-to-day operation and maintenance of spectrometer 1.9 T and Bruker AM400WB spectrometers as well as electronics design and construction. Excellent opportunities for collaborative research in biophysical and biomedical applications of NMR. Candidates should possess the equivalent of an MS or PhD degree with substantial NMR experience.

Competitive salary and excellent benefits. Send 2 copies of résumé including salary requirement and names of three references to: Department of Personnel Services, The Milton S. Eshelman Medical Center of the Pennsylvania State University, P.O. Box 850, Hershey, PA 17033 (717) 534-8440. An Equal Opportunity/Affirmative Action Employer. (NW186)A

NATURE CONSERVANCY COUNCIL HIGHER SCIENTIFIC OFFICER/SENIOR SCIENTIFIC OFFICER Fen Peatlands Specialist

Applications are invited for the above permanent post to be based in the Nature Conservancy Council's headquarters in Peterborough. The post holder will be required to review and plan the long-term needs and strategy for conservation of fen peatlands as well as to supply information and advice to NCC and others on fenland conservation. The successful applicant will be required to represent NCC at meetings and on committees and through general liaison with appropriate bodies, institutions and people.

Qualifications: Applicants should have a degree in an appropriate subject with at least four years postgraduate experience related to the post and have a good record of published work. Experience of working in nature conservation and of speaking in public, including committee work, would be preferable.

Salary depending on qualifications and experience: HSO £7,785 rising to £10,541, SSO £9,772 rising to £12,653.

For an application form and for further details of the post please contact Miss B A Meredith, Personnel, Nature Conservancy Council, Northminster House, Peterborough, PE1 1UA, to whom completed forms should be returned by 19 September 1985.

The Nature Conservancy Council is an equal opportunity employer.

UNIVERSITY OF LONDON Royal Free Hospital School of Medicine

DEPARTMENT OF BIOCHEMISTRY AND CHEMISTRY RESEARCH ASSISTANT GRADE 1A

To work on the nature of lipoprotein-binding to platelets and the mechanism of lipoprotein-induced platelet potentiation. Applicants should not be more than 28 years old, have a PhD in biochemistry or a related subject and preferably have experience in receptor studies.

The post is for three years, supported by a grant from the Medical Research Council to Dr K R Bruckdorfer.

Further details from the School Office, RFHSM, Rowland Hill Street, London, NW3 2PF (01-794-0500 extn 4262) to which full curriculum vitae and the names and addresses of two academic referees should be sent by 11 September 1985. Please quote reference KRB/RA. (7516)A

WEST MIDDLESEX HOSPITAL

Isleworth, Middlesex

DEPARTMENT OF RHEUMATOLOGY

Applications are invited from suitable qualified people for a position funded by Action Research for the Crippled Child to investigate immunological mechanisms in scleroderma. Experience in cell lines and culture essential.

Salary up to £12,690 (including London Weighting).

For further information please contact Carol Black at the above address. Telephone 01 568 2842. (7495)A

MEDICAL RESEARCH COUNCIL CLINICAL & POPULATION CYTOGENETICS UNIT BIOLOGIST

Applications are invited for a Short-Term Non-Clinical Scientific post in the above Unit, tenable for 3 years from October 1985. Candidates of immediately post-doctoral or equivalent status, and having some experience in cytogenetics or relevant molecular biology will be preferred. The appointee will work with a group using DNA probes in studies on chromosome anomalies in normal and malignant human cells.

Remuneration will be at an appropriate point on the scales for University non-Clinical academic staff. Further details from, and applications, with names and addresses of two referees, to the Administrator, MRC Clinical and Population Cytogenetics Unit, Western General Hospital, Crewe Road, Edinburgh EH4 2XU, by September 9th, 1985, quoting reference HJ/2989.

Faculty Positions available at Assistant, Associate and Full Professor levels in the newly established Center for Biotechnology. The Center consists of three divisions: (i) Hybridoma Technology; (ii) Recombinant DNA Technology and (iii) Cellular and Molecular Neurobiology.

Applicants should have research background in one of these areas. Experience and interest in biotechnological applications are desirable but not required.

Please send résumé, a brief description of research experience and future goals, and names of several references to:

Dr. Dominic Man-Kit Lam, Director

**The Center for Biotechnology
Baylor College of Medicine
Houston, Texas 77030**

Louisiana Geological Survey at Louisiana State University
has one anticipated

Research Position

B.S. or M.S. in wetlands ecology/botany or marine science; knowledge of wetland soils, plant communities; 2 or more years' experience in wetlands ecology research. Knowledge of air photo interpretation, photogrammetry, geologic/hydrologic characteristics of wetlands preferred.

To participate in field work monitoring wetlands changes in coastal Louisiana; prepare publications; interact with other ongoing coastal investigations of a more geologic nature.

Send résumé, 3 references and publications to: Dr Lindsay Nakashima, Louisiana Geological Survey, Box G, Baton Rouge, LA 70893, by 9/30/85. An Affirmative Action/Equal Opportunity Employer (NW193)A

THE UNIVERSITY OF ALABAMA AT BIRMINGHAM DEAN OF THE SCHOOL OF OPTOMETRY

The University of Alabama at Birmingham is seeking applications and nominations for the position of Dean of the School of Optometry. The Dean is the chief administrative officer of the School of Optometry and is responsible to the Senior Vice President for Health Affairs for the administration of all educational and research programs conducted by the School of Optometry.

The School of optometry is one of six health professional schools in the UAB Medical Center (the others are Medicine, Dentistry, Nursing, Public Health, and Community and Allied Health). The Medical Center schools are closely related through cooperative programs and collaborative research. Programs offered by the School of Optometry include the professional curriculum in optometry, graduate programs (M.S. and Ph.D.) in physiological optics, optometric residency training, continuing education for practicing optometrists, and basic and applied vision research. The research activities are supported in part by a Vision Research Center Grant from the National Eye Institute.

Applications and nominations should include a curriculum vitae, the names of three references, and any other supporting material deemed appropriate. To be assured of full consideration, these should be submitted by December 31, 1985, to:

**Dr Joseph F. Volker
Chairman
School of Optometry Dean Search Committee
The University of Alabama at Birmingham
Box 85 SDB
University Station
Birmingham AL 35294**

UAB is an affirmative action, equal opportunity employer

UNIVERSITY OF FLORIDA Institute of Food and Agricultural Sciences DEAN FOR RESEARCH

Responsible for basic and applied research programs in agriculture and related areas. The statewide research programs are located in 23 on-campus departments, 23 outlying centers, the School of Forest Resources and Conservation, and the College of Veterinary Medicine. The Dean reports to the Vice President for Agricultural Affairs. Earned doctorate degree in agriculture or closely related scientific fields is required

Applicants are to submit a résumé and names of five references by October 15, 1985 to G. W. Isaacs, Agricultural Engineering Department, Rogers Hall, Gainesville, FL 32611. (NW184)A

THE UNIVERSITY OF ADELAIDE

invites applications from both men and women for the following two positions.

TWO LECTURESHIPS IN DEPARTMENT OF AGRONOMY (Tenurable)

in the Waite Agricultural Research Institute

Applicants should have wide interests, and a demonstrated research competence, in field-oriented aspects of agronomic constraints to crop and pasture production. Their interests might range from the influence of management on plant development and production to systems analysis. Persons with experience in any aspect of agronomy are encouraged to apply: the two examples given below which are not intended to be exclusive represent areas of research that the Department would consider to be appropriate

Crop Water Relations. Applicants in this field would have experience in plant water relations with a demonstrated capacity for field research and be capable of developing a research program into the limitations imposed by water on the yield of annual crops

Weed Science. Applicants in this field would have experience in weed biology or weed ecology and be capable of developing a research program on the interaction of weed populations with herbicides and the cultural practices of crop cultivation. A knowledge of weed taxonomy may be an advantage

The Department of Agronomy has eleven academic staff positions

including the two currently being advertised. Research activities include crop nutrition, pasture management, crop physiology, herbicide resistance; cereals and grain legume genetics and breeding

Further information may be obtained from Professor C.J. Driscoll (tel. (08) 372 2444 Ext 279)

Holders of full-time tenured or tenurable academic appointments have the opportunity to take leave without pay on a half-time basis for a specific period of up to ten years when this is necessary for the care of children

It is University policy to encourage women to apply for consideration for appointment to tenurable academic appointments

Information about the general conditions of all appointments may be obtained from the Senior Assistant Registrar (Personnel), at the University.

Salary per annum. \$A26,235 × 7 — \$A34,467.

Applications, in duplicate, quoting reference numbers E1068 and E1072, and giving full personal particulars (including whether candidates hold Australian permanent residency status), details of academic qualifications and names and addresses of three referees, should reach the Senior Assistant Registrar (Personnel), at the University of Adelaide, GPO Box 498, Adelaide, South Australia 5001 (telex: UNIVAD AA89141) not later than 25 October 1985

The University reserves the right to make enquiries of any person regarding any candidate's suitability for appointment, not to make an appointment or to appoint by invitation (W2166)A

PRE- AND POST-DOCTORAL POSITIONS

Pre- and post-doctoral positions are currently available in a multi-disciplinary program of studies of vascular structure and function, in particular with respect to hypertension and diabetes.

Applicants for pre-doctoral positions will be expected to have obtained a good degree in either Anatomy, Physiology or Pharmacology, or other degree with related course work. Stipends of \$8,000 (Cdn) per annum are available on a competitive basis.

Annual salary for the post-doctoral positions commences at \$19,200 (Cdn) and a relocation allowance is available

Send curriculum vitae, statement of research interests, and the names of three academic references to:

Dr. T. M. Scott, Professor of Anatomy, Faculty of Medicine, Memorial University of Newfoundland, St. John's, Newfoundland, Canada A1B 3X6. (NW183)A

FACULTY POSITION IN GENETICS UNIVERSITY OF WASHINGTON

Applications are invited for an Assistant Professor position in Genetics with a beginning date between September 1986 and September 1987.

Candidates should have a Ph.D. degree, postdoctoral experience and demonstrated accomplishments in research.

Responsibilities will include teaching and research. Interested persons should submit a curriculum vitae, a description of research plans and three letters of reference to:

**Chairman, Search Committee
Department of Genetics, SK-50
University of Washington
Seattle, Washington 98195**

The University of Washington is an Equal Opportunity Employer (NW194)A

UNIVERSITY OF LONDON Wye College POSTDOCTORAL OR POSTGRADUATE RESEARCH ASSISTANT

In The Molecular Genetics of Plant Disease

Applications are invited for an AFRC funded post to apply molecular biology to studies on the determinants of pathogenicity in the fireblight disease caused by *Erwinia amylovora*. The appointment is tenable for 3 years and will involve collaboration with the John Innes Institute and East Malling Research Station. Salary will depend on qualifications and experience. Starting date, 1st November or a mutually convenient date.

Candidates should have experience in microbial genetics or biochemical plant pathology

Enquiries and applications, including a curriculum vitae and the names of two referees, should be sent to Dr J.W. Mansfield, Plant Sciences Department, Wye College, Ashford, Kent, TN25 5AH. Closing date 12 September 1985 (7525)A

OXFORDSHIRE HEALTH AUTHORITY The Churchill Hospital DEPARTMENT OF MEDICAL GENETICS

Applications are invited for graduates with an appropriate or upper second class hon degree for the post of Senior Officer (basic grade) in Cytogenetics Laboratory of above Department. This laboratory provides a chromosome diagnosis service to the Oxford Region and Scientific Officer will, after training if necessary, be capable of culturing a range of human tissues, processing the cultures, preparing chromosome slides and analysing preparations. The salary will be in the range of £5,937 — £8 depending upon qualifications and experience

Application form and description from the Personnel Officer, The Churchill Hospital, Headington, Oxford.

Closing date — 12th September 1985. (7528)

SEMINARS & SYMPOSIA

International Symposium on Artificial Organs,
Biomedical Engineering & Transplantation

THE SALT PALACE • SALT LAKE CITY, UTAH, U.S.A. • JANUARY 20-23, 1986

In honour of the 75th birthday of W. J. Kolff, the father of artificial organs

A state-of-the-art scientific program featuring international **scientific papers competition** with **four £10,000 prizes**. Deadline for abstracts **September 1, 1985**.

Sponsored by the University of Utah Research Foundation, the American Society for Artificial Internal Organs, the International Society for Artificial Organs, the Biomedical Engineering Society and the Society for Biomaterials

For additional information write, telex or call:

International Symposium Registration Center
P.O. Box 17413
Washington-Dulles International Airport
Washington, DC 20041 USA

Phone (703) 471-5761 Telex. 899133 (WHITEPO) (NW115)M

FELLOWSHIPS

EMBO

EUROPEAN MOLECULAR BIOLOGY ORGANIZATION SHORT TERM FELLOWSHIPS in molecular biology

The European Molecular Biology Organisation awards, to scientists working in Europe and Israel in the field of molecular biology and allied disciplines, short term fellowships of one week up to three months duration. The fellowships are to support collaborative research between laboratories in different countries and provide a travel grant and subsistence allowance. Applications may be made at any time and are decided upon soon after the receipt of application.

Applications for exchanges between laboratories within any one country cannot be considered. Fellowships involving transatlantic travel are awarded only in extremely exceptional circumstances.

Application forms and further details may be obtained from Dr J. Tooze, Executive Secretary, European Molecular Biology Organization, 69 Heidelberg 1, Postfach 102240, F.R.G. (W1577)E

CHARING CROSS MEDICAL RESEARCH CENTRE

Immunology Unit

POSTDOCTORAL RESEARCH FELLOWSHIP IN IMMUNOLOGY

Applications are invited for a Research Fellowship funded by MRC to work in the group of Dr Marc Feldmann on a project to examine mechanism of immunological tolerance using human T cell clones in vitro. Preference will be given to candidates with experience of T cell cloning with an interest in immune regulation.

Appointment will be for 3 years, starting October 1st, 1985, with starting salary at the appropriate point of Research 1A scale, depending on age, qualifications and experience.

Applications (with curriculum vitae, publications list and name of two referees) should be sent to: The Administrator, Charing Cross Medical Research Centre, Lurgan Avenue, Hammersmith, London W6 8LW. (7509)E

POSTDOCTORAL FELLOWSHIP

Available now to work on molecular genetics of immunoglobulin regulation. Must have experience in mRNA purification, translation assays, reverse transcription and cDNA cloning and sequencing. One year fellowship assured with possibility of further funding. Desire unusually self-motivated individual to work in University of Texas Medical School (Houston) following approx. 2 month skills — apprenticeship in Philadelphia.

Apply: Dr. Benjamin Wolf, University of Pennsylvania, School of Veterinary Medicine, 3800 Spruce Street, Philadelphia, PA 19104. (NW196)E

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE

(University of London)

JUNIOR RESEARCH FELLOWSHIP

Applications are invited for a Junior Research Fellowship tenable in the Department of Physiology from 1 October 1985. Applicants should have (or expect to obtain) a First or Upper Second Class Honours Degree in Physiology, Pharmacology or related Biological Science.

The successful applicant will be expected to register for a Ph D.

Enquiries regarding the nature and range of available projects should be addressed to Professor K M Sayer, Department of Physiology, Royal Free Hospital School of Medicine, Rowland Hill Street, London NW3 2PF (01-794 0500, Ext. 4301). (7514)E

CHARING CROSS MEDICAL RESEARCH CENTRE

Immunology Unit

POSTDOCTORAL RESEARCH FELLOW IN MOLECULAR BIOLOGY

Applications are invited for a Research Fellowship to work in Dr Marc Feldmann's group in a project to analyse mechanisms of HLA Class II antigen regulation in disease. Candidates should hold or expect to obtain a doctorate in Molecular Biology, Biochemistry or relevant experience.

Appointment will be for 3 years on the appropriate point of Research 1A scale, depending on age, qualifications and experience.

Applications (with curriculum vitae, publications list and name of three referees) should be sent to: The Administrator, Charing Cross Medical Research Centre, Lurgan Avenue, Hammersmith, London W6 8LW. (7508)E

THE UNIVERSITY OF WESTERN AUSTRALIA Perth

UNIVERSITY RESEARCH FELLOWSHIPS (POSTDOCTORAL)

Up to four Research Fellowships will be offered, to be taken up as soon as possible in 1986, but no later than twelve months after the date of offer. Appointment will normally be for two years in the first instance. Fellowships may be renewed for a third year, but only in competition with new applications. Fellows who are appointed for two years in the first instance shall be required to join the Superannuation Scheme for Australian Universities (SSAU). The Fellowships will be tenable in the following academic departments for work in the broad areas stated below.

Anatomy and Human Biology
Biochemistry

Civil Engineering

Mathematics
Microbiology

Pharmacology
Physics

Physiology

The Field of Stereology

Analysis of gene expression using recombinant DNA technology
Investigation of mixing in a stratified fluid

Group theory and combinatorics
Molecular analysis on flavivirus genomes

Drug Metabolism

Electron Scattering in Atomic Physics

Molecular biology of hepatic carcinogenesis

The Fellowships are intended for younger, accomplished research worker who have held a PhD or equivalent qualification for not more than five years and who by publication and in other ways have demonstrated significant research capability, they are not normally available to immediate PhD graduates of the University of Western Australia. Commencing Salary will be within the range of \$A22,614 — \$A25,905 per annum. The removal allowance for an appointee from outside Australia is currently a maximum of \$A3,616.

Applications in duplicate setting out full personal particulars, qualifications and relevant experience should reach the Staffing Officer, University of Western Australia, Nedlands, Western Australia 6009, by 30th September 1985. Copies of the principles governing University Research Fellowships are available from the Staffing Officer, or from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. Applicants should arrange for three referees to write to the Staffing Officer before the closing date. (W2154)E

Scientific Research Fellowships

ROYAL AIRCRAFT ESTABLISHMENT, FARNBOROUGH

There are vacancies for Research Fellows at RAE Farnborough to take part in a wide range of interesting and challenging research. The work is at the forefront of aerospace science and technology, and examples of the many research topics available are —

- Signal Processing/Pattern Recognition
- Airborne Communications/Navigation
- Aircraft and Helicopter Simulators/Man Machine Interface
- IKBS applied to aircraft systems
- Computational Fluid Dynamics
- Aerodynamics, thermodynamics and mechanical aspects of gas turbines
- Application of advanced materials to airframe structures

Research staff have access to large modern test facilities including wind tunnels, moving base simulators, advanced computer and graphics systems, a variety of aircraft for flight tests, engine research rigs, etc.

Successful candidates will be encouraged to establish links with Universities and other Research organisations and be given the opportunity to publish and present their work at International level.

Qualifications and Salary

Candidates must have a good Honours Degree or equivalent, show evidence of research ability and have at least 2-3 years postgraduate research experience. Fellowships are awarded for periods of 3 to 5 years and remuneration is assessed in the range £7,334 to £15,573 pa.

For more information and application forms contact **Staff Personnel Branch, Royal Aircraft Establishment, Farnborough, Hants GU14 6TD. Please quote reference: (N)**

Closing date for applications. 20th September 1985. The Civil Service is an equal opportunity employer (7494)E

CONFERENCES & COURSES

**The New York Academy of Sciences
Conference on
ADVANCES IN ELECTRON AND LIGHT
Optical Imaging in Biology
and Medicine**

March 18-21, 1986

Barbizon-Plaza Hotel, New York City

The conference will have a broad scope in covering both methodology and significant results obtained with a variety of imaging and preparatory techniques; including cryomicroscopy, image processing, high and intermediate high voltage electron microscopy, scanning transmission electron microscopy, electron probe X-ray microanalysis, electron energy loss spectroscopy, photo-electron microscopy, acoustic microscopy, X-ray microscopy, digitally processed and scanning confocal light microscopy.

Chairman: Andrew P. Somlyo, M.D., Director, Pennsylvania Muscle Institute, University of Pennsylvania School of Medicine, Philadelphia, PA 19104.

Inquiries should be addressed to: Conference Department, The New York Academy of Sciences, 2 East 63rd Street, New York, NY 10021.

(NW200)C

**ANNOUNCING NATURE'S FIFTH
INTERNATIONAL CONFERENCE**

**UPDATE IN
MOLECULAR
BIOLOGY
1985**

**Genes and
Systems in
Development**

October 7, 8, 9, 1985

Sheraton-Palace Hotel, San Francisco
Presented in conjunction with the University
of California at San Francisco

- Poster Sessions
- Tax-Deductible
- CMEs will be awarded
- Registration Fee

Early Registration Fee \$350 (before September 15)

Gala conference dinner \$29.50 per person.

Conference Themes

Day 1: Systems | Day 2: Cells | Day 3: Genes

FELLOWSHIPS

**RESEARCH
FELLOWSHIPS**

Gonville and Caius College intends to elect to one or more Research Fellowships to commence 1st October 1986. The Fellowships are open to all graduates of or research students in a University of the British Isles who were born after 1st September 1957. Applications for the Fellowships must be received by 7th October 1985.

Full particulars may be obtained from the Master's Secretary, Gonville and Caius College, Cambridge CB2 1TA.

**UNIVERSITY OF LONDON
King's College London (KQC)
MSc DEGREE IN
GENERAL BIOCHEMISTRY**

Both part-time and full-time courses will commence in October 1985 and will be held at the Campden Hill site, Kensington. The part-time course extends over two academic years and involves attendance for one afternoon and one evening per week. The full-time course extends over one academic year and involves a research project.

Qualifications: Candidates should normally hold a first or second class honours degree (or an approved equivalent qualification) in a science subject. Graduates in Medicine, Dentistry or Veterinary Medicine are also admitted. The course is inappropriate to recent graduates from honours Biochemistry courses.

For further information and application forms write, in the first instance, to the Secretary, Biochemistry Department, King's College London (KQC), Atkins Building, Campden Hill, London, W8 7AH
(7520)C

ASSISTANTSHIPS

DURHAM UNIVERSITY

DEPARTMENT OF PHYSICS

Applications are invited for a

**POSTDOCTORAL
SENIOR RESEARCH
ASSISTANTSHIP**

tenable for three years. The successful applicant will participate in a theoretical research programme of study of physical and chemical processes in the interstellar medium.

Initial salary in the range £7,520 — £8,920 (under review) with superannuation.

Applications (3 copies), naming three referees should be sent by 16 September 1985 to the Registrar, Science Laboratories, South Road, Durham DH1 3LE, from whom further particulars may be obtained.

MARINE BIOLOGIST. Ph.D. 1985. Desperately seeks research or industrial employment, anything considered. Experience with benthic fauna in field and laboratory. Experienced diver. Box No. 7521 c/c Nature, 4 Little Essex Street London WC2R 3LF (7521)B

The Pharmacia Vertical Electrophoresis System

Doing more... and more

Pharmacia is known and respected worldwide for the excellence of its electrophoresis products and experience. Typical of our expertise in this field is the Vertical Gel Electrophoresis System. At its heart lies the GE 2/4 LS Electrophoresis Apparatus; a rugged, versatile unit packed with time- and trouble-saving features. This one unit will run all your routine gels in either slabs or rods.

More flexibility

Means designing a complete system with components that work together perfectly

Combined with the innovative electronics of the digital Power Supply EPS 500/400 and the Volthour Integrator VH-1, the GE 2/4 LS is unbeatable.

More innovation

Means setting new standards with the Electronic Power Supply and Volthour Integrator

Choose from a range of gel rod and slab casting kits or, for speed and quality, use Pharmacia precast gels PAA 2/16 and PAA 4/30.

More choice

Means a range of gel casting apparatus and 16 types of gel rod and slab cassette kits

Your system is complete with the Gel Destainer GD-4 and the Gel Slab Drier GSD-4.

More services

Means a comprehensive package of technical literature to help you to get even more out of your Electrophoresis System

Do DISC-PAGE, SDS-PAGE, Gradient PAGE or High Resolution 2-D electrophoresis. In fact, do it all with the Pharmacia Vertical Gel Electrophoresis System.

Contact your Pharmacia representative today for a complete information package
